Conclusions: The hematocrit target of <45% was associated with a lower incidence of CV death, major thrombotic events, and superficial veinous thrombosis in patients with polycythemia vera.
H42 Hematology

Myeloproliferative Neoplasms

- gout (hyperuricemia)
  - due to increased cell turnover
- characteristic physical findings
  - plethora (ruddy complexion) of face (70%), palms
  - splenomegaly (70%), hepatomegaly (40%)

Investigations
- see Erythrocytosis, H6
- must rule out secondary polycythemia if high Epo level

Treatment
- phlebotomy to keep hematocrit <45%
- hydroxyurea (prior thrombosis or symptoms, severe coronary artery disease, refractory to phlebotomy)
- low-dose Aspirin® (for antithrombotic prophylaxis, will also treat erythromelalgia)
- allopurinol: as needed
- antihistamines: as needed

Prognosis
- 10-20 yr survival with treatment
- complicated by thrombosis, hemorrhage, leukemic transformation (AML)

Idiopathic Myelofibrosis

Definition
- excessive bone marrow fibrosis leading to marrow failure
- characterized by anemia, extramedullary hematopoiesis, leukoerythroblastosis, teardrop red cells in peripheral blood and hepatosplenomegaly

Epidemiology
- rare, median age at presentation is 65 yr

Pathophysiology
- abnormal myeloid precursor postulated to produce dysplastic megakaryocytes that secrete fibroblast growth factors
  - stimulates fibroblasts and stroma to deposit collagen in marrow
  - increasing fibrosis causes early release of hematopoietic precursors leading to:
    - leukoerythroblastic blood film (primitive RBCs and WBCs present in blood)
    - migration of precursors to other sites: extramedullary hematopoiesis (leading to hepatosplenomegaly)

Clinical Features
- anemia (severe fatigue is most common presenting complaint, pallor on exam in >60%)
- weight loss, fever, night sweats → secondary to hypermetabolic state
- splenomegaly (90%) → secondary to extramedullary hematopoiesis; may cause early satiety
- hepatomegaly (70%) → may get portal hypertension
- bone and joint pain → secondary to osteosclerosis, gout
- signs of extramedullary hematopoiesis (depends on organ involved)

Investigations
- CBC: anemia variable platelets, variable WBC
- biochemistry: increased ALP (liver involvement, bone disease) increased LDH (2ª to ineffective hematopoiesis), increased uric acid (increased cell turnover), increased B12 (2º to increased neutrophil mass)
- blood film: leukoerythroblastosis with teardrop RBCs, nucleated RBCs, variable polychromasia, large platelets, and megakaryocyte fragments
- JAK2 PCR and calreticulin PCR
- bone marrow aspirate: “dry tap” in as many as 50% of patients (no blood cells aspirated)
- bone marrow biopsy (essential for diagnosis): fibrosis, atypical megakaryocytic hyperplasia, thickening and distortion of the bony trabeculae (osteosclerosis)

Treatment
- allogeneic stem cell transplant is potentially curative
- JAK2 inhibitors (Ruxolitinib)
- symptomatic treatment
  - transfusion for anemia
  - erythropoietin: 30-50% of patients respond
  - androgens for anemia (e.g. danazol has shown transient response with response rates of <30%)
  - hydroxyurea for splenomegaly, thrombocytosis, leukocytosis, systemic symptoms
    - nterferon-a (as second line therapy)
    - splenectomy (as third line therapy; associated with high mortality and morbidity)
  - radiation therapy for symptomatic extramedullary hematopoiesis, symptomatic splenomegaly

Efficacy and Safety of Low-dose Aspirin® in Polycythemia Vera

Study: Double-blind, placebo-controlled, RCT
Participants: 518 patients with polycythemia vera (PV) with no clear indication for, or contraindication to, ASA therapy.
Intervention: Patients received either low-dose ASA 100 mg daily (n=263) or placebo (n=255) and were followed for up to 5 yr.
Primary Outcome: Cumulative rate of (I) nonfatal MI, nonfatal stroke, or death from cardiovascular causes and the cumulative rate of (II) the previous 3 plus PE and major venous thrombosis.
Results: Primary outcomes (I) and (II) were reduced with treatment compared to placebo (RR 0.41, p = 0.03 and RR 0.4, p = 0.03, respectively). There were no differences in overall or cardiovascular mortality and major bleeding episodes.
Conclusion: Low-dose ASA can safely prevent thrombotic complications in patients with PV.

Myelofibrosis can be either primary (idiopathic) or occur as a transformation of an antecedent PV or ET

A “leukoerythroblastic” blood film (RBC and granulocyte precursors) implies bone marrow infiltration with malignancy (e.g. leukemias, solid tumour metastases) or fibrosis (e.g. IMF)

IMF typically has a dry BM aspirate and teardrop RBCs (aspiration gives no blood cells)

A Double-Blind, Placebo-Controlled Trial of Ruxolitinib for Myelofibrosis

Study: Double-blind RCT of 309 patients with myelofibrosis randomized to ruxolitinib or placebo
Outcome: Primary outcome was reduction in spleen volume of >35% at 24 wk. Secondary outcomes were durability of response, symptom burden, and overall survival.
Results: A greater proportion of patients on ruxolitinib had reduction in spleen volume >35% (41.9% vs. 0.7%) and this was sustained in 67% at 48 wk. Ruxolitinib also led to greater symptom improvement (46% vs. 5.5%) and less mortality (13 vs 24). There was no difference in rate of discontinuation due to adverse events (11.0% vs. 10.6%) but anemia and thrombocytopenia were more common with ruxolitinib.
Conclusions: Ruxolitinib reduced spleen size, improved symptoms and improved survival, compared with placebo.
Prognosis
- Dynamic International Prognostic Scoring System (DIPSS) Plus for IMF uses 5 risk factors along with karyotype, platelet count, and transfusion status to predict survival
  - presence of constitutional symptoms; age >65; hemoglobin <100 g/L; leukocyte count >25,000/mm³; circulating blast cells ≥1%
  - based on the calculated score, a patient's IMF is categorized as "low", "intermediate 1", "intermediate 2", or "high" with a mean survival of 185, 78, 35, and 16 mo, respectively
- risk of transformation to AML (8-10%)

Essential Thrombocythemia

Definition
- overproduction of platelets in the absence of recognizable stimulus
- must rule out secondary thrombocythemia

Epidemiology
- increases with age; F:M = 2:1, but F=M at older age

Diagnosis (2008 WHO Criteria) requires meeting all four criteria:
1. sustained platelet count >450 x 10⁹/L
2. bone marrow biopsy specimen showing proliferation mainly of the megakaryocytic lineage with increased number of enlarged, mature megakaryocytes; no significant increase or left shift of neutrophil granulopoiesis or erythropoiesis
3. not meeting WHO criteria for PV, primary myelofibrosis, bcr-abl CML, or myelodysplastic syndrome or other myeloid neoplasms
4. demonstration of JAK2 V617F or calreticulin (or in its absence another clonal marker), no evidence for reactive thrombocytosis

Clinical Features
- often asymptomatic
- vasomotor symptoms (40%)
  - headache (common), dizziness, syncope
  - erythromelalgia (burning pain of hands and feet, dusky colour, usually worse with heat, caused by platelet activation → microvascular thrombosis)
- thrombosis (arterial and venous)
- bleeding often GI; associated with platelets >1,000 x 10⁹/L
- constitutional symptoms, splenomegaly
- pregnancy complications; increased risk of spontaneous abortion
- risk of transformation to AML (0.6-5%), myelofibrosis

Investigations
- CBC: increased platelets; may have abnormal platelet aggregation studies or vWD studies
- JAK2 PCR assay; if negative, CALR PCR assay
- bone marrow hypercellularity, megakaryocytic hyperplasia, giant megakaryocytes
- increased K⁺, increased PO₄³⁻ (2⁺ to release of platelet cytoplasmic contents)
- diagnosis: exclude other myeloproliferative disorders and reactive thrombocytosis

Treatment
- low dose ASA if previous history of thrombotic event, ≥1 cardiovascular risk factors, older, or symptomatic
- cytoreductive therapy if thrombosis or thrombotic symptoms: hydroxyurea (HU) (1st line therapy), anagrelide, interferon-α, or 32P (age >80 or lifespan <10 yr)

Etiology of Secondary Thrombocythemia
- Infection
- Inflammation (IBD, arthritis)
- Malignancy
- Hemorrhage
- Iron deficiency
- Hemolytic anemia
- Post splenectomy
- Post chemotherapy

Anagrelide vs. Hydroxyurea for Essential Thrombocythemia: ANAHYDRET Study, A Randomized Controlled Trial
Blood 2013;121:1720-8
Study: Prospective, non-inferiority, RCT. Majority of patients followed beyond 1 yr
Population: 259 previously untreated, high-risk patients with essential thrombosis as per the WHO guidelines.
Intervention: Patients were randomized to receive either non-immediate release formulation of anagrelide or hydroxyurea.
Outcome: Examined platelet counts, hemoglobin levels, leukocyte count, and occurrence of ET-related events.
Results: The hazard ratio (HR) of developing thrombocytemia was 1.19 (95% CI 0.61-2.30). The HR for a reduction of hemoglobin was 1.63 (95% CI 0.57-4.81), and 0.92 (95% CI 0.37-1.48) for leukocytosis. There was no statistical difference in occurrence of major or minor arterial or venous thrombosis, severe or minor bleeding events, or rate of discontinuation between the two arms.
Conclusions: In patients with ET, anagrelide is non-inferior to hydroxyurea in the prevention of thrombotic complications.
Lymphoid Malignancies

Acute Lymphoblastic Leukemia

Definition
- malignant disease of the bone marrow in which early lymphoid precursors proliferate and replace the normal hematopoietic cells of the marrow
- WHO subdivides ALL into two types depending on cell of origin
  - 1. B-cell: precursor B lymphoblastic leukemia
  - 2. T-cell: precursor T lymphoblastic leukemia
- the French-American-British (FAB) classification (L1, L2, L3) is no longer encouraged, as morphology is not prognostic

Clinical Features
- see Acute Myeloid Leukemia, H37 for full list of symptoms
- distinguish ALL from AML based on Table 32
- clinical symptoms usually secondary to:
  - bone marrow failure: anemia, neutropenia (50% present with fever; also infections of oropharynx, lungs, perianal region), thrombocytopenia
  - organ infiltration: tender bones, lymphadenopathy, hepatosplenomegaly, meningeal signs (headache, N/V, visual symptoms; especially in ALL relapse)

Investigations
- CBC: increased leukocytes >10 x 10⁹/L (occurs in 50% of patients); neutropenia, anemia, or thrombocytopenia
- may have increased uric acid, K⁺, PO₄³⁻, Ca²⁺, LDH
- PT, aPTT, fibrinogen, D-dimers for DIC
- leukemic lymphoblasts lack specific morphological (no granules) or cytochemical features, therefore diagnosis depends on immunophenotyping
- cytogentics: Philadelphia (Ph) chromosome in ~25% of adult ALL cases
- CXR: patients with ALL may have a mediastinal mass
- LP prior to systemic chemotherapy to assess for CNS involvement (ensure adequate platelet count and PT/PTT)

Treatment
- eliminate abnormal clonal cells
  1. induction chemotherapy: to induce complete remission (undetectable leukemic blasts, restore normal hematopoiesis)
  2. consolidation and/or intensification of chemotherapy
    - consolidation: continuing same chemotherapy to eliminate subclinical leukemic cells
    - intensification: high doses of different (non-cross-reactive) chemotherapy drugs to eliminate cells with resistance to primary treatment
  3. maintenance chemotherapy: low dose intermittent chemotherapy over prolonged period (2-3 yr) to prevent relapse
  4. prophylaxis: CNS radiation therapy or methotrexate (intrathecal or systemic)
- hematopoietic stem cell transplantation: potentially curative (due to pre-implant myeloablative chemoradiation and post-implant graft-versus-leukemia effect) but relapse rates and non-relapse mortality high

Prognosis
- depends on response to initial induction or if remission is achieved following relapse
- good prognostic factors: young, WBC <30 x 10⁹/L, T cell phenotype, absence of Ph chromosome, early attainment of complete remission
- achievement of first remission: 60-90%
- childhood ALL: 75% long-term remission (>5 yr)
  - higher cure rates in children because of better chemotherapy tolerance, lower prevalence of BCR-Abl fusion gene (associated with chemotherapeutic resistance)
- adult ALL: 30-40% 5 yr survival

75% of ALL occurs in children < 6 yr old; second peak at age 40
**Lymphomas**

**Definition**
- collection of lymphoid malignancies in which malignant lymphocytes accumulate at lymph nodes and lymphoid tissues
  - leading to lymphadenopathy, extranodal disease, and constitutional symptoms

**Hodgkin Lymphoma**

**Definition**
- malignant proliferation of lymphoid cells with Reed-Sternberg cells (thought to arise from germinal centre B-cells)

**Epidemiology**
- bimodal distribution with peaks at 20 yr and >50 yr
- association with Epstein-Barr virus in up to 50% of cases, causal role not determined

**Clinical Features**
- asymptomatic lymphadenopathy (70%)
  - non-tender, rubbery consistency
  - cervical/supraclavicular (60-80%), axillary (10-20%), inguinal (6-12%)
  - splenomegaly (50%) ± hepatomegaly
  - mediastinal mass
    - found on routine CXR, may be symptomatic (cough)
    - rarely may present with SVC syndrome, pleural effusion
  - systemic symptoms
    - B symptoms (especially in widespread disease; fever in 30%), pruritus
  - non-specific/paraneoplastic
    - alcohol-induced pain in nodes, nephrotic syndrome
  - starts at a single site in lymphatic system (node), spreads first to adjacent nodes
    - disease progresses in contiguity with lymphatic system

**Investigations**
- CBC
  - anemia (chronic disease, rarely hemolytic), eosinophilia, lymphopenia, platelets normal or increased early, decreased in advanced disease
- biochemistry
  - HIV serology
  - liver enzymes and/or LFTs (liver involvement)
  - renal function tests (prior to initiating chemotherapy)
  - ALP, Ca²⁺ (bone involvement)
  - ESR, LDH (monitor disease progression)
- imaging
  - CXR, CT chest (lymph nodes, mediastinal mass), CT abdomen/pelvis (liver or spleen involvement)
  - PET scans have replaced gallium scans

American Society of Hematology Choosing Wisely Recommendation
Limit surveillance CT scans in asymptomatic patients after curative-intent treatment for aggressive lymphoma

- Ann Arbor staging can be used for both Hodgkin and non-Hodgkin lymphoma, but grade/histology is more important for non-Hodgkin lymphoma because the outcome differs significantly depending on type of lymphoma
- Prognostic scores are different for indolent versus aggressive lymphomas
- Highly aggressive lymphomas act like acute leukemias

Hodgkin lymphoma is distinguished from non-Hodgkin lymphoma by the presence of Reed-Sternberg cells

Hodgkin lymphoma classically presents as a painless, non-tender, firm, rubbery enlargement of superficial lymph nodes, most often in the cervical region
• cardiac function assessment (MUGA scan or echocardiography): for patients at high risk of pre-treatment cardiac disease (age >60, history of HTN, CHF, PUD, CAD, MI, CVA, malnourished), treatment can be cardiotoxic
  • PFTs: if history of lung disease (COPD, smoking, previous radiation to lung)
  • excisional lymph node or core biopsy confirms diagnosis
  • bone marrow biopsy to assess marrow infiltration (only necessary if B-symptoms, stage III or IV, bulky disease or cytopenia)

Treatment
  • stage I-II: chemotherapy (ABVD) followed by involved field or involved site radiotherapy (XRT)
  • stage III-IV: chemotherapy (ABVD) with XRT for bulky disease
  • relapse, resistant to therapy: high dose chemotherapy, autologous stem cell transplant
  • PET scan results essential in clarifying disease response

Complications of Treatment
  • cardiac disease: secondary to XRT, adriamycin is also cardiotoxic
  • pulmonary disease secondary to bleomycin (interstitial pneumonitis)
  • infertility: recommend sperm banking
  • secondary malignancy in irradiated field
    • <2% risk of MDS, AML (secondary to treatment, usually within 8 yr)
    • solid tumours of lung, breast; >8 yr after treatment
  • non-Hodgkin lymphoma
  • hypothyroidism: post XRT

Prognosis
  • Hasenclever adverse prognostic factors:
    1. serum albumin <40 g/L
    2. hemoglobin <105 g/L
    3. male
    4. stage IV disease
    5. age ≥45 yr
    6. leukocytosis (WBC >1.5 x 10⁹/L)
    7. lymphocytopenia (lymphocytes <0.06 x 10⁹/L or <8% of WBC count or both)
  • prognostic score
    • each additional adverse prognostic factor decreases freedom from progression at 5 yr (FFP)

Non-Hodgkin Lymphoma

Definition
  • malignant proliferation of lymphoid cells of progenitor or mature B- or T-cells

Classification
  • multiple classification systems exist at present and may be used at different centres
  • can originate from both B- (85%) and T- or NK- (15%) cells
    • B-cell NHL: e.g. diffuse large B-cell lymphoma, follicular lymphoma, Burkitt’s lymphoma, mantle cell lymphoma
    • T-cell NHL: e.g. mycosis fungoides (skin), TCL-NOS, anaplastic large cell lymphoma
  • WHO/REAL classification system: 3 categories of NHLs based on natural history
    • indolent (35-40% of NHL): e.g. follicular lymphoma, small lymphocytic lymphoma/CLL, mantle cell lymphoma
    • aggressive (~50% of NHL): e.g. diffuse large B-cell lymphoma
    • highly aggressive (~5% of NHL): e.g. Burkitt’s lymphoma

Clinical Features
  • painless superficial lymphadenopathy, usually >1 lymph node region
  • usually presents as widespread disease (exception is aggressive lymphoma)
  • constitutional symptoms not as common as in Hodgkin lymphoma
  • cytopenia: anemia ± neutropenia ± thrombocytopenia can occur when bone marrow is involved
  • abdominal signs
    • hepatosplenomegaly
    • retroperitoneal and mesenteric involvement (second most common site of involvement)
    • oropharyngeal involvement in 5-10% with sore throat and obstructive apnea
    • extranodal involvement: most commonly GI tract; also testes, bone, kidney
    • CNS involvement in 1% (often with HIV)

Investigations
  • CBC
    • normocytic normochromic anemia
    • autoimmune hemolytic anemia rare
    • advanced disease: thrombocytopenia, neutropenia, and leukoerythroblastic anemia
  • peripheral blood film may show lymphoma cells
• flow cytometry of peripheral blood lymphocytosis is valuable for low-grade NHL
• biochemistry
  ■ increase in uric acid
  ■ abnormal LFTs in liver metastases
  ■ increased LDH (rapidly progressing disease, poor prognostic factor)
• staging: CT neck, chest, abdomen, pelvis and bone marrow biopsy
• PET is useful for monitoring response to treatment and evaluation of residual tumour following therapy in aggressive histological disease
• diagnosed by
  ■ lymph node biopsy: excisional biopsy preferred, FNA unreliable
  ■ bone marrow biopsy: not optimal for diagnosis as BM involved in only 30% of high grade lymphomas

Treatment
• localized disease (e.g. GI, brain, bone, head and neck)
  ■ radiotherapy to primary site and adjacent nodal areas
  ■ adjuvant chemotherapy
• surgery: splenic marginal zone lymphoma
• indolent lymphoma: goal of treatment is symptom management
  ■ watchful waiting
  ■ radiation therapy for localized disease
  ■ bendamustine plus rituximab, an anti-CD20 antibody, is superior to CHOP + rituximab (CHOP R) for advanced stage disease (StiLL trial)
• aggressive lymphoma: goal of treatment is curative
  ■ combination chemotherapy: CHOP is mainstay, plus rituximab if B-cell lymphoma
  ■ radiation for localized/bulky disease
  ■ CNS prophylaxis with high-dose methotrexate if certain sites involved (testicular)
  ■ relapse, resistant to therapy: high dose chemotherapy, autologous SCT
• highly aggressive lymphoma
  ■ Burkitt lymphoma: short bursts of intensive chemotherapy “CODOX-M” chemotherapy regimen also often used ± IVAC with Rituximab
  ■ CNS prophylaxis and tumour lysis syndrome prophylaxis

Complications
• hypersplenism
• infection
• autoimmune hemolytic anemia and thrombocytopenia
• vascular obstruction (from enlarged nodes)
• bowel perforation
• tumour lysis syndrome (particularly in very aggressive lymphoma) see Tumour Lysis Syndrome, H52

Prognosis
• follicular lymphoma: Follicular Lymphoma International Prognostic Index is used (5 adverse prognostic factors): age >60; >4 nodal areas; elevated LDH; Lugano stage III-IV; hemoglobin <120 g/L
  ■ based on calculated risk, mean 5 yr survival ranges from 53-91%
  ■ rarely curative, typically relapsing and remitting course with risk of transformation to aggressive lymphoma such as diffuse large B-cell lymphoma
• diffuse large B-cell lymphoma: The International Prognostic Factor Index is used (5 adverse prognostic factors): age >60; Ann Arbor stage (III-IV); performance status (ECOG/Zubrand 2-4); elevated LDH; >1 extranodal site
  ■ based on calculated risk, mean 5 yr survival ranges from 26-73%
  ■ ~40% rate of cure

**Chronic Lymphocytic Leukemia**

**Definition**
- indolent disease characterized by clonal malignancy of mature B-cells

**Epidemiology**
- most common leukemia in Western world
- mainly older patients; median age 70 yr
- M>F

**Pathophysiology**
- accumulation of neoplastic lymphocytes in blood, bone marrow, lymph nodes, and spleen

**Clinical Features**
- 25% asymptomatic (incidental finding)
- 5-10% present with B-symptoms (≥1 of: unintentional weight loss ≥10% of body weight within previous 6 mo, temperature >38ºC or night sweats for ≥2 wk without evidence of infection, extreme fatigue)
- lymphadenopathy (50-90%), splenomegaly (25-55%), hepatomegaly (15-25%)
- immune dysregulation: autoimmune hemolytic anemia (DAT positive), ITP, hypogammaglobulinemia + neutropenia
- bone marrow failure: late, secondary to marrow involvement by CLL cells

**Investigations**
- CBC: clonal population of B lymphocytes >5 x 10⁹/L
- peripheral blood film
  - lymphocytes are small and mature
  - smudge cells
- flow cytometry (CD5, CD20dim, CD23)
- cytogenetics: FISH (dictates response therapy and prognosis)
- bone marrow aspirate
  - lymphocytes >30% of all nucleated cells
  - infiltration of marrow by lymphocytes in 4 patterns: nodular (10%), interstitial (30%), diffuse (35% worse prognosis), or mixed (25%)

**Natural History and Treatment**
- natural history: indolent and incurable; most cases show slow progression
- small minority present with aggressive disease; usually associated with chromosomal abnormalities (e.g. p53 deletion)
- first line therapy is dictated by cytogenetic status and patient co-morbidities
  - observation if early, stable, asymptomatic
  - treatment options vary by region; ideal first line therapy should include a monoclonal CD20 agent (e.g. rituximab, obinutuzumab)
    - commonly fludarabine + cyclophosphamide + rituximab (FCR) in fit patients with normal CrCl; bendamustine + rituximab (BR) in less fit
    - chlorambucil + anti-CD20 obinutuzumab in the elderly
    - corticosteroids, IVIg: especially for autoimmune phenmenonradiotherapy
- molecular therapies
  - Idelalisib – PI3K inhibitor
  - Ibr timib – BTK (Bruton’s tyrosine kinase) inhibitor

Rouleaux formation on peripheral blood smear, if not artifact, denotes hyperglobulinemia (but not necessarily monoclonality)

Smudge cells are artifacts of damaged lymphocytes from slide preparation.
**Prognosis**
- 9 yr median survival, but varies greatly
- prognosis predicted by Rai staging and cytogenetic status
- low risk: lymphocytosis in blood and bone marrow only
- intermediate risk: lymphocytosis with enlarged nodes in any site or splenomegaly, hepatomegaly
- high risk: lymphocytosis with disease-related anemia (<110 g/L) or thrombocytopenia (<100 x 10⁹/L)

**Complications**
- bone marrow failure
- immune complications: AIHA, ITP, immune deficiency (hypogammaglobulinemia, impaired T-cell function)
- polyclonal or monoclonal gammopathy (often IgM)
- hyperuricemia with treatment
- 5% undergo Richter's transformation: aggressive transformation to diffuse large B-cell lymphoma (see Table 35)

**Multiple Myeloma**

**Definition**
- neoplastic clonal proliferation of plasma cells producing a monoclonal immunoglobulin resulting in end organ dysfunction
- usually single clone of plasma cells, although biclonal myeloma also occurs; rarely non-secretory

**Epidemiology**
- incidence 3 per 100,000, most common plasma cell malignancy
- increased frequency with age; median age of diagnosis is 68 yr; M>F

**Pathophysiology**
- malignant plasma cells secrete monoclonal antibody
  - 95% produce M protein (monoclonal Ig = identical heavy chain + identical light chain, or light chains only)
    - IgG 50%, IgA 20%, IgD 2%, IgM 0.5%
    - 15-20% produce free light chains or light chains alone found in either:
      - serum as an increase in the quantity of either kappa or lambda light chain (with an abnormal kappa:lambda ratio)
      - urine has Bence-Jones protein
  - <5% are non-secretors

**Clinical Features and Complications**
- bone disease: pain (usually back), bony tenderness, pathologic fractures
  - lytic lesions are classical (skull, spine, proximal long bones, ribs)
- increased bone resorption secondary to osteoclast activating factors such as PTHrP
- anemia: weakness, fatigue, pallor
  - secondary to bone marrow suppression
- weight loss
- infections
  - usually *S. pneumoniae* and Gram-negatives
  - secondary to suppression of normal plasma cell function
- hypercalcemia: N/V confusion, constipation, polyuria, polydipsia
  - secondary to increased bone turnover
- renal disease/renal failure
  - most frequently causes cast nephropathy (see Nephrology, NP32)
- bleeding
  - secondary to thrombocytopenia, may see petechiae, purpura
  - can also be caused by acquired von Willebrand disease
- extramedullary plasmacytoma
  - soft tissue mass composed of monoclonal plasma cells, purplish colour
- hyperviscosity: may manifest as headaches, stroke, angina, MI
  - secondary to increased viscosity caused by M protein
- amyloidosis
  - accumulation of insoluble fibrillar protein (Ig light chain) in tissues; can cause infiltration of any organ system: cardiac infiltration – diastolic dysfunction, cardiac arrhythmias, syncope, sudden death; GI involvement – malabsorption, beefy large or laterally scalloped tongue; neurologic involvement – orthostatic hypotension, carpal tunnel syndrome
  - may cause Factor X deficiency if fibrils bind Factor X → bleeding (raccoon eyes)
  - neurologic disease: muscle weakness, pain, paresthesias
  - radiculopathy caused by vertebral fracture, extramedullary plasmacytoma
- spinal cord compression (10-20% of patients) is a medical emergency

**Amyloid**
The general term for a variety of proteinaceous materials that have a similar structural organization and are abnormally deposited in tissues

Found in a variety of clinical disorders and can cause systemic (e.g. MM [light chains]) or localized amyloidosis (e.g. Alzheimer disease [AB amyloid])
Investigations

- **CBC**
  - normocytic anemia, thrombocytopenia, leukopenia
- **biochemistry**
  - increased Ca\(^{2+}\), increased ESR, decreased anion gap, increased Cr, albumin, β2-microglobulin (as part of staging), proteinuria (24 h urine collection)
- **monoclonal proteins**
  - serum protein electrophoresis (SPEP): demonstrates monoclonal protein spike in serum in 80% (i.e. M protein)
  - urine protein electrophoresis (UPEP): demonstrates light chains in urine = Bence-Jones protein (15% secretes only light chains)
  - immunofixation: demonstrates M protein and identifies Ig type; also identifies light chains
  - serum free light chain quantification: kappa and lambda light chains, calculated ratio
- **bone marrow aspirate and biopsy**
  - often focal abnormality; greater than 10% plasma cells, abnormal morphology, clonal plasma cells; send for FISH or cytogenetics (prognostic implications)
- **skeletal series (X rays), MRI if symptoms of cord compression**
  - presence of lytic lesions and areas at risk of pathologic fracture
  - bone scans are not useful since they detect osteoblast activity
- **β2-microglobulin, LDH, and CRP are poor prognosticators**

Diagnosis

- **International Myeloma Working Group Criteria**
  1. serum or urinary monoclonal protein
  2. presence of clonal plasma cells in bone marrow (>60% without “CRAB”) or a plasmacytoma
  3. presence of end-organ damage related to plasma cell dyscrasia, such as:
     - increased serum Ca\(^{2+}\)
     - lytic bone lesions
     - anemia
     - renal failure

Treatment

- treatment is non-curative
- **treatment goals**
  - improvement in quality of life (improve anemia, reverse renal failure, bony pain)
  - prevention of progression and complications
  - increase overall survival
- **autologous stem cell transplant if <65 yr old**
  - usually preceded by 4-6 mo of cytoreductive therapy: steroid based with novel agents (i.e. immunomodulatory drugs or proteasome inhibitors)
- **chemotherapy if >65 yr old or transplant ineligable**
  - melphalan, prednisone, cyclophosphamide and proteasome inhibitor (i.e. bortezomib)
  - dexamethasone and bortezomib if ARF; bortezomib ± dexamethasone in light chain amyloidosis
- **supportive management**
  - bisphosphonates for those with osteopenia or lytic bone lesions (requires renal dosing)
  - local XRT for bone pain, spinal cord compression
  - kyphoplasty for vertebral fractures to improve pain relief and regain height
  - treat complications: hydration for hypercalcemia and renal failure, bisphosphonates for severe hypercalcemia, prophylactic antibiotics, erythropoietin for anemia, DVT prophylaxis
- **all patients will relapse; choice of retreatment regimen depends on duration of remission, organ involvement, patient's comorbidities, and preferences**

Prognosis

- **ISS - International Staging System (β2-microglobulin and albumin) used to stage and estimate prognosis**
  - revised ISS for risk stratification: combination of original ISS, cytogenetic profile (i.e. p53 mutation associated with poor survival and resistance to chemotherapy) and LDH
  - median survival based on stage, usually 3-7 yr
Monoclonal Gammopathy of Unknown Significance

**Definition**
- presence of M protein in serum in absence of any clinical or laboratory evidence of a plasma cell dyscrasia or lymphoproliferative disorders
  - incidence: 0.15% in general population, 5% of people >70 yr of age
  - asymptomatic

**Diagnosis**
- presence of a serum monoclonal protein (M protein) at a concentration <30 g/L
- <10% plasma cells in bone marrow
- absence of hyperCalcemia, Renal insufficiency, Anemia, Bone disease related to the plasma cell proliferative process (absence of “CRAB”)
- 0.3-1% of patients develop a hematologic malignancy each yr
  - patients with M protein peak ≥15 g/L or patients with IgA or IgM MGUS are at higher risk of malignant transformation
  - patients with abnormal serum free light chains ratio are at increased risk of malignant transformation
- monitor with annual history, physical, CBC, Cr, calcium, albumin, serum protein electrophoresis (considered pre-malignant)

Lymphoplasmacytic Lymphoma
(Waldenstrom’s Macroglobulinemia)

**Definition**
- proliferation of lymphoplasmacytoid cells
  - presence of monoclonal IgM paraprotein

**Clinical Features**
- chronic disorder of elderly patients; median age 64 yr
- symptoms: weakness, fatigue, bleeding (oronasal), weight loss, recurrent infections, dyspnea, CHF (triad of anemia, hyperviscosity, plasma volume expansion), neurological symptoms, peripheral neuropathy, cerebral dysfunction
- signs: pallor, splenomegaly, hepatomegaly, lymphadenopathy, retinal lesions
- key complication to avoid: hyperviscosity syndrome
  - because IgM (unlike IgG) confined largely to intravascular space

**Investigations and Diagnosis**
- bone marrow shows plasmacytoid lymphocytes
- bone lesions usually not present
- blood work rarely see hypercalcemia
- cold hemagglutinin disease possible: Raynaud’s phenomenon, hemolytic anemia precipitated by cold weather
- normocytic anemia, rouleaux, high ESR if hyperviscosity not present

**Treatment**
- Bendamustine – R/R-CVP chemotherapy, alkylating agents (chlorambucil), nucleoside analogues (Iluadabine), rituximab, or combination therapy
- corticosteroids
- plasmapheresis for hyperviscosity: acute reduction in serum IgM

Complications of Hematologic Malignancies

Hyperviscosity Syndrome

**Definition**
- refers to clinical sequelae of increased blood viscosity (when relative serum viscosity >5-6 units), resulting from increased circulating serum IgGs or from increased cellular blood components in hyperproliferative disorders (e.g. multiple myeloma, leukemia, PV)
- Waldenstrom's macroglobulinemia accounts for 85% of cases

**Clinical Features**
- hypervolemia causing: CHF, headache, lethargy, dilutional anemia
- CNS symptoms due to decreased cerebral blood flow: headache, vertigo, ataxia, stroke
- retina shows venous engorgement and hemorrhages
- bleeding diathesis
  - due to impaired platelet function, absorption of soluble coagulation factors (e.g. nasal bleeding, oozing gums)
- ESR usually very low

**Treatment**
- plasmapheresis, chemotherapy
**Tumour Lysis Syndrome**

**Definition**
- group of metabolic complications that result from spontaneous or treatment-related breakdown of cancer cells
- more common in diseases with large tumour burden and high proliferative rate (high grade lymphoma, leukemia)

**Clinical Features**
- metabolic abnormalities
  - cells lyse, releasing K⁺, uric acid, PO₄³⁻ (increased levels)
  - PO₄³⁻ binds Ca²⁺ (decreased Ca²⁺)
- complications
  - lethal cardiac arrhythmia (increased K⁺)
  - acute kidney injury (formerly known as renal failure) see Nephrology, NP18

**Treatment**
- prevention
  - aggressive IV hydration
  - allopurinol or rasburicase
  - correction of pre-existing metabolic abnormalities
  - dialysis

---

**Blood Products and Transfusions**

**Blood Products**
- RBCs, platelets and coagulation factors (frozen plasma [FP], cryoprecipitate, factor concentrates) are available for transfusion
- donated blood (1 U = 450-500 mL) is fractionated into these various components
  - centrifugation separates whole blood into RBCs and platelet-rich plasma
  - platelet-rich plasma is further fractionated into platelets and plasma
  - need to pool together multiple units to obtain therapeutic amounts
  - FP (previously known as FFP) is plasma frozen within 24 h of collection
  - cryoprecipitate is the high MW precipitate generated when FP is thawed at low temperatures

**Specialized Products**
- irradiated blood products
  - prevent proliferation of donor T-cells in potential or actual bone marrow transplant recipients
  - used for immunocompromised patients or for patients on purine analogue chemotherapy, first-degree relatives, HLA-matched products and intrauterine transfusions, Hodgkin lymphoma
- CMV-negative blood products
  - potential transplant recipients
  - neonates
  - AIDS patients
  - seronegative pregnant women

**Blood Groups**

<table>
<thead>
<tr>
<th>Group</th>

<td>A</td>
<td>Anti-B</td>
</tr>
<tr>
<td>B</td>
<td>B</td>
<td>Anti-A</td>
</tr>
<tr>
<td>AB</td>
<td>A and B</td>
<td>Nil</td>
</tr>
</tbody>
</table>

In Canada, blood products are leukodepleted via filtration immediately after donation; therefore it is considered:
- Low in lymphokines, resulting in a lower incidence of febrile nonhemolytic transfusion reactions
- CMV negative (because CMV is found in leukocytes)

**Red Blood Cells**

**Packed Red Blood Cells**
- stored at 4°C
- transfuse within 42 d of collection, otherwise cell lysis may result in hyperkalemia
- infuse each unit over 2 h (max of 4 h)

**Indications for Packed RBC Transfusion**
- Hb <70 g/L; this may change as per patient's tolerance or symptoms
  - maintain Hb between 70 and 100 g/L during active bleeds
  - consider maintaining a higher Hb for patients with:
    - CAD/unstable coronary syndromes
    - uncontrolled, unpredictable bleeding
    - impaired pulmonary function
    - increased O₂ consumption

1 unit of pRBC will increase Hb by approximately 10 g/L or increase Hct by 4%

**American Society of Hematology Choosing Wisely Recommendation**
Do not transfuse more than the minimum number of RBC units necessary to relieve symptoms of anemia or to return the patient to a safe hemoglobin range (70-80 g/L) in stable non-cardiac patients
Selection of Red Cells for Transfusion

- when anticipating an RBC transfusion, the following should be ordered:
  - group and screen: determines the blood group and Rh status of the recipient as well as the presence of autoantibodies vs. major/minor blood group antigens in the patient's serum
  - cross-match: involves mixing the recipient's blood with potential donor blood and looking for agglutination (takes 30-45 min)
- when blood is required, several options are available
  - 1st line: fully crossmatched blood, electronic crossmatch is becoming more widely used (not always available in emergency situations)
  - 2nd line: donor blood of the same group and Rh status as the recipient
  - 3rd line: O- blood for females of reproductive age; O+ blood for all others

Table 37. Platelet Products

<table>
<thead>
<tr>
<th>Product</th>
<th>Indication</th>
</tr>
</thead>
<tbody>
<tr>
<td>Random Donor (Pooled)</td>
<td>Thrombocytopenia with bleeding</td>
</tr>
<tr>
<td>Single Donor Platelets</td>
<td>Potential BMT recipients</td>
</tr>
<tr>
<td>HLA Matched Platelets</td>
<td>Refractory to pooled or single donor platelets, presence of HLA antibodies</td>
</tr>
</tbody>
</table>

- stored at 20-24°C
  - random donor platelets are transfused from a pool of 4 units; this should increase the platelet count by \( \geq 15 \times 10^9/L \)
  - single donor platelets (transfused as single units) should increase the platelet count by 40-60 \( \times 10^9/L \)
  - if an increase in the platelet count is not seen post-transfusion: autoantibodies (i.e. ITP), alloantibodies, consumption (bleeding, sepsis), or hypersplenism may be present

</table>
Acute Blood Transfusion Reactions

IMMUNE

Acute Hemolytic Transfusion Reactions
ABO incompatibility resulting in intravascular hemolysis secondary to complement activation, occurs immediately after transfusion
- most commonly due to incorrect patient identification
- risk per unit of blood is <1 in 40,000
- presentation: fever, chills, hypotension, back or flank pain, dyspnea, hemoglobinuria
- acute renal failure (<24 h) and DIC
- treatment
  - stop transfusion
  - notify blood bank and check for clerical error
  - maintain BP with vigorous IV fluids ± inotropes
  - maintain urine output with diuretics, crystalloids, dopamine

Febrile Nonhemolytic Transfusion Reactions
- due to alloantibodies to WBC, platelets or other donor plasma antigens, and release of cytokines from blood product cells
- occurs within 0-6 h of transfusion
- risk per unit of blood is 1 in 100 (minor), 1 in 10,000 to 40,000 (severe)
- presents with fever ± rigors, facial flushing, headache, myalgia, hypotension
- treatment
  - rule out hemolytic reaction or infection
  - if temperature <38ºC, continue with transfusion but decrease rate and give antipyretics
  - if temperature >38ºC, stop transfusion, give antipyretics and anti-histamine

Allergic Nonhemolytic Transfusion Reactions
- alloantibodies (IgE) to proteins in donor plasma result in mast cell activation and release of histamine
- occurs mainly in those with history of multiple transfusions or multiparous women
- risk per unit of blood is 1 in 100
- presents mainly as urticaria and occasionally with fever
- can present as anaphylactoid reaction with bronchospasm, laryngeal edema, and hypotension, but this occurs mainly in IgA deficient patients that have anti-IgA antibodies
- treatment
  - mild: slow transfusion rate and give diphenhydramine
  - moderate to severe: stop transfusion, give IV diphenydramine, steroids, epinephrine, IV fluids, and bronchodilators

Transfusion-Related Acute Lung Injury
- new-onset acute lung injury that occurs during transfusion or within 6 h of transfusion completion
- insidious, acute onset of pulmonary insufficiency
- profound hypoxemia (PaO2/FiO2 <300 mmHg)
- bilateral pulmonary edema on CXR
- pulmonary artery wedge pressure <18 mmHg
- no clinical evidence of left atrial hypertension
- pathogenesis uncertain; perhaps due to binding of donor antibodies to WBC of recipient and release of mediators that increase capillary permeability in the lungs
- typically occurs 2-4 h post transfusion and resolves in 24-72 h
- risk per unit of blood is 1 in 10,000
  - is currently the leading cause of transfusion-related morbidity and mortality
- treatment: supportive therapy (oxygen)
  - inform blood bank; patient and donor testing will be arranged

NONIMMUNE

Transfusion-Associated Circulatory Overload
- due to impaired cardiac function and/or excessive rapid transfusion
- presentation: dyspnea, orthopnea, hypotension, tachycardia, crackles at base of lung, and increased venous pressure
- incidence: 1 in 700 and is becoming more common
- treatment: transfuse at lower rate, give diuretics and oxygen

Bacterial Infection
- Gram-positive: S. aureus, S. epidermidis, Bacillus cereus
- Gram-negative: Klebsiella, Serratia, Pseudomonas, Yersinia
- overall risk is 1 in 100,000 for RBC and 1 in 10,000 for platelets
- never store blood >4 h after bag has left blood bank
- treatment: stop transfusion, blood cultures, IV antibiotics, fluids
Hyperkalemia
- due to K⁺ release from stored RBC
- risk increases with storage time and if blood is irradiated and risk decreases if given fresh blood
- occurs in 5% of massively transfused patients
- treatment: see Nephrology, NP13

Citrate Toxicity
- occurs with massive transfusion in patients with liver disease – patients are unable to clear citrate from blood
- citrate binds to Ca²⁺ and causes signs and symptoms of hypocalcemia
- treatment: IV calcium gluconate (10 mL for every 2 units of blood)

Dilutional Coagulopathy
- occurs with massive transfusion (>10 units)
- pRBC contains no clotting factors, fibrinogen, cryoprecipitate, or platelets
- treatment: FFP, cryoprecipitate, and platelets

Delayed Blood Transfusion Reactions

**IMMUNE**

Delayed Hemolytic
- due to alloantibodies to minor antigens such as Rh, Kell, Duffy, and Kidd
- level of antibody at time of transfusion is too low to cause hemolysis; later the level of antibody increases due to secondary stimulus and causes extravascular hemolysis
- occurs 5-7 d after transfusion
- presentation: anemia and mild jaundice
- treatment: no specific treatment required; important to note for future transfusion
- N.B. serologic transfusion reactions are the development of alloantibodies in the absence of frank hemolysis

Transfusion-Associated Graft Versus Host Disease
- transfused T-lymphocytes recognize and react against “host” (recipient)
- occurs 4-30 d following transfusion
- most patients already have severely impaired immune systems (e.g. Hodgkin lymphoma or leukemia)
- presentation: fever, diarrhea, liver function abnormalities and pancytopenia
- can be prevented by giving irradiated blood products

**NONIMMUNE**

Iron Overload
- due to repeated transfusions over long period of time (e.g. β-thalassemia major)
- can cause secondary hemochromatosis
- treatment: iron chelators or phlebotomy if no longer requiring blood transfusion and not anemic

Viral Infection Risk
- HBV 1 in 1.1 to 1.7 million
- HCV 1 in 5 to 7 million
- HIV 1 in 8 to 12 million
- Human T-lymphotropic virus (HTLV) 1 in 1 to 1.3 million
- other infections include EBV, CMV, WNV (West Nile virus)
**Common Medications**

### Antiplatelet Therapy

- see Figure 11a, Platelet Activation Cascade, H26

![Image of mechanisms of action of antiplatelet therapy](Image)

**Figure 15. Mechanisms of action of antiplatelet therapy**

**Table 40. Antiplatelet Therapy**

<table>
<thead>
<tr>
<th>Medication</th>
<th>Mechanism of Action</th>
<th>Dose/Route of Administration</th>
<th>Onset/Peak/Duration</th>
<th>Specific Side Effects</th>
<th>Remarks</th>
</tr>
</thead>
</table>
| **Aspirin® (ASA)** | Irreversibly acetylates COX, inhibiting TXA2 synthesis, thus inhibiting platelet aggregation | Single loading 200-300 mg PO, followed by dose of 75-100 mg PO daily | Onset: 5-30 min Peak: 0-25-3 h Duration: 3-6 h | GI ulcer/bleeding Tinnitus Bronchospasm Angioedema Reye’s syndrome in pediatric patients | - Indicated for stroke/MI prophylaxis
- Reduce incidence of recurrent MI
- Decrease mortality in post-MI patients
- Contraindicated in patients with GI ulcers |
| **Aggrenox® (ASA + Dipyridamole)** | Dipyridamole increases intracellular cAMP levels, which inhibits TXA2 synthesis, leading to decreased platelet aggregation | 1 capsule PO bid Peak: 75 min | | Dyspepsia N/V Abdominal pain Cardiac failure Hemorrhoids | - More effective than ASA in secondary prevention of stroke
- Dipyridamole potentiates antiplatelet action of ASA |
| **Clopidogrel (Plavix®)** | Irreversibility inhibit ADP binding to platelets, thus decreased platelet aggregation | 75-300 mg PO daily | Onset: 2 h Peak: 1 h | URI Chest pain Flu-like syndrome Depression UTI GI hemorrhage Pancytopenia | Prevention of cardiovascular events in high-risk patients
Clopidogrel is a prodrug requiring two-step activation to active metabolite CYP2C19 poor metabolizers have diminished response to clopidogrel
Cautions with hepatic/renal impairment |
| **Prasugrel (Effient®)** | Same as clopidogrel | 5-10 mg PO daily | Onset: 30 min | Dizziness H/A Nervousness Blurry vision | Alternative to clopidogrel for prevention of cardiovascular events in high-risk patients
Higher potency compared to clopidogrel
No significant drug-drug interaction, although more data is required |

</tbody>
</table>

Adverse Reactions of Heparin
- Hemorrhage: depends on dose, age, and concomitant use of antiplatelet agents or thrombolytics
- Heparin-induced thrombocytopenia: associated with venous or arterial thrombosis (see Table 22, H29)
- Osteoporosis: with long-term use

Low Molecular Weight Heparin (enoxaparin, dalteparin, tinzaparin)
- Increased bioavailability compared to normal heparin
- Increased duration of action
- SC route of administration
- Do not need to monitor aPTT
- Adverse reactions less common than UFH
- Patients with renal failure (CrCl <30 mL/min) can accumulate LMWH, therefore must adjust dose
- Only partially reversible with protamine sulfate
- HIT is less common

# Landmark Hematology Trials

## Hematologic Malignancies and Related Disorders

<table>
<thead>
<tr>
<th>Trial</th>
<th>Reference</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hodgkin Lymphoma: ABVD vs. MOPP</td>
<td>NEJM 1992;327:1478-84</td>
<td>In Hodgkin lymphoma, ABVD regimen has equal or better free and overall survival to MOPP + ABVD, but less myelotoxicity; ABVD is standard chemotherapy for Hodgkin lymphoma.</td>
</tr>
<tr>
<td>CHOP</td>
<td>NEJM 1993;328:1002-6</td>
<td>In NHL, CHOP has lowest incidence of fatal toxic reactions and shows no significant difference from 3 other regimens in response or disease-free/overall survival; CHOP is the standard for advanced NHL.</td>
</tr>
<tr>
<td>R-CHOP</td>
<td>NEJM 2002;346:235-42</td>
<td>Addition of rituximab to CHOP increases complete response rate and prolongs event-free survival and overall survival in elderly with DLBCL.</td>
</tr>
<tr>
<td>CML: Imatinib vs. IFN + Cytarabine</td>
<td>NEJM 2003;349:994-1004</td>
<td>In patients with chronic-phase CML, imatinib was more effective than IFNα + cytarabine in inducing cytogenetic response and freedom from progression to accelerated phase/blast crisis.</td>
</tr>
<tr>
<td>CLL8</td>
<td>Lancet 2010;376:1164-74</td>
<td>Rituximab plus fludarabine and cyclophosphamide (FRD) improves progression-free and overall survival compared with fludarabine and cyclophosphamide alone (FC) in the treatment of CLL.</td>
</tr>
<tr>
<td>VISTA</td>
<td>JCO 2010;28:2259-66</td>
<td>Bortezomib plus melphalan and prednisone (MPV) is superior to melphalan and prednisone (MP) in overall survival of non-transplant-eligible multiple myeloma patients.</td>
</tr>
<tr>
<td>MInT Group</td>
<td>Lancet 2011;12:1013-1022</td>
<td>Rituximab added to CHOP-like chemotherapy improved long-term outcomes for young patients with good-prognosis DLBCL.</td>
</tr>
<tr>
<td>StIL</td>
<td>Lancet 2013;381(9873):1203-10</td>
<td>Bendamustine plus rituximab is superior to R CHOP in terms of progression-free survival and fewer toxic effects in patients with previously untreated indolent lymphoma.</td>
</tr>
<tr>
<td>Ibrutinib vs. Ofatumumab in previously treated CLL</td>
<td>NEJM 2014;371:213-223</td>
<td>Ibrutinib, as compared with ofatumumab, significantly improved progression-free survival, overall survival, and response rate among patients with previously treated CLL or SLL.</td>
</tr>
</tbody>
</table>

## Thrombosis

<table>
<thead>
<tr>
<th>Trial</th>
<th>Reference</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLOT</td>
<td>NEJM 2003;349:146-53</td>
<td>In patients with cancer and acute venous thromboembolism, LWMH was more effective than warfarin in reducing the risk of recurrent thromboembolism without increasing the risk of bleeding.</td>
</tr>
<tr>
<td>PT1</td>
<td>NEJM 2005;353:35-6</td>
<td>Hydroxyurea plus low-dose ASA is superior to anagrelide plus low-dose ASA for patients with essential thrombocythemia at high risk for vascular events.</td>
</tr>
<tr>
<td>ESPRIT</td>
<td>Lancet 2006;367:1665-73</td>
<td>ASA plus dipyridamole is recommended over ASA alone as antithrombotic therapy after cerebral ischemia of arterial origin.</td>
</tr>
<tr>
<td>Dabigatran vs. Warfarin in VTE</td>
<td>NEJM 2009;361:2342-52</td>
<td>In the treatment of venous thromboembolism, dabigatran is as effective as warfarin and also has a similar safety profile; note: many problems in the trial, making it less pivotal in having drug approval.</td>
</tr>
<tr>
<td>E NSTEIN-PE</td>
<td>NEJM 2012;366:1287-1297</td>
<td>Among patients with acute PE, rivaroxaban is noninferior to warfarin in preventing recurrent VTE, and is associated with similar bleeding rates.</td>
</tr>
<tr>
<td>AMPLIFY</td>
<td>NEJM 2013;369:799-808</td>
<td>In patients with VTE who have completed 6-12 months of anticoagulation, long-term apixaban treatment reduces recurrent VTE or all-cause mortality without increasing rates of major bleeding.</td>
</tr>
<tr>
<td>RE-VERSE AD</td>
<td>NEJM 2015;373:511-520</td>
<td>Idarucizumab for dabigatran reversal.</td>
</tr>
</tbody>
</table>

## Blood Products and Transfusion

<table>
<thead>
<tr>
<th>Trial</th>
<th>Reference</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>Platelet Transfusion Threshold</td>
<td>NEJM 1997;337:1870-5</td>
<td>The risk of major bleeding in patients with AML undergoing induction chemotherapy was similar whether the platelet-transfusion threshold was set at 20 or 10; use of the lower threshold reduced platelet usage by 21.5%.</td>
</tr>
<tr>
<td>TRICC BP</td>
<td>NEJM 1999;340:409-17</td>
<td>A restrictive strategy of red-cell transfusion (when Hb &lt;70) is at least as effective as and possibly superior to a liberal transfusion strategy (when Hb &lt;100) in ICU patients; one possible exception is patients with an acute MI or unstable angina.</td>
</tr>
<tr>
<td>Dose of Platelet Transfusion</td>
<td>NEJM 2010;362:600-13</td>
<td>Low dose prophylactic platelet transfusion decreases total number of platelets transfused but increases number of transfusions but not incidence of bleeding in patients with hypoproliferative thrombocytopenia.</td>
</tr>
<tr>
<td>Transfusion in High-Risk Patients after Hip Surgery</td>
<td>NEJM 2011;365:2453-2462</td>
<td>A liberal transfusion strategy (Hb &lt;100), as compared with a restrictive strategy (anemia symptoms or at physician discretion for Hb &lt;80), did not reduce rates of death or inability to walk independently on 60-day follow-up or reduce in-hospital morbidity in elderly patients at high cardiovascular risk.</td>
</tr>
<tr>
<td>Therapeutic Platelet Transfusion</td>
<td>Lancet 2012;380:1309-16</td>
<td>Therapeutic platelet transfusions (when bleeding occurs) may be used if severe bleeding can be identified early in autologous stem-cell transplant patients; prophylactic transfusion (when platelets &lt;10) should remain standard of care in AML patients.</td>
</tr>
<tr>
<td>Transfusion Strategies for Acute Upper GI Bleeding</td>
<td>NEJM 2013;368:11-21</td>
<td>As compared with a liberal transfusion strategy (Hb &lt;90), a restrictive strategy (Hb &lt;70) significantly improved outcomes in patients with acute upper gastrointestinal bleeding.</td>
</tr>
</tbody>
</table>

## Other

<table>
<thead>
<tr>
<th>Trial</th>
<th>Reference</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSH</td>
<td>NEJM 1995;332:1317-22</td>
<td>Hydroxyurea is effective in reduction of complications and clinical manifestations of sickle cell disease.</td>
</tr>
<tr>
<td>ITP: Dexamethasone</td>
<td>NEJM 2003;349:831-6</td>
<td>A four-day course of high-dose dexamethasone is effective initial therapy for adults with immune thrombocytopenic purpura.</td>
</tr>
<tr>
<td>CRASH-2</td>
<td>Health Technol Assess 2013;17(10):1-79</td>
<td>Early administration of TXA safely reduced the risk of death in bleeding trauma patients and is highly cost-effective. Treatment beyond 3 hours of injury is unlikely to be effective.</td>
</tr>

**Principles of Microbiology**

### Bacteriology

**Bacteria Basics**
- bacteria are prokaryotic cells that divide asexually by binary fission
- Gram stain divides most bacteria into two groups based on their cell wall
  - Gram positive (GP): thick, rigid layer of peptidoglycan
  - Gram negative (GN): thin peptidoglycan layer + thicker outer membrane composed of lipoproteins and lipopolysaccharides
- clinical significance: GN thick outer membrane makes it resistant to penicillin’s mechanism of action
- acid-fast bacilli (AFB): high mycolic acid content in cell wall, “acid fast” as washout phase with acid-alcohol is ineffective in acid-fast bacteria, e.g. Mycobacteria, Nocardia
- “atypical” bacteria: not seen on Gram stain and difficult to culture
  - obligate intracellular bacteria: e.g. Chlamydia, Chlamydia phila
  - bacteria lacking a cell wall: Mycoplasma
  - spirochetes: e.g. Treponema pallidum
- O2 can be either vital or detrimental to growth
  - obligate aerobes: require O2
  - obligate anaerobes: require environment without O2
  - facultative anaerobes: can survive in environments with or without O2

**Mechanisms of Bacterial Disease**
1. adherence to and colonization of skin or mucous membranes
   - fimbriae (pili): microfilaments extending through the cell wall attach to epithelial cells (e.g. E. coli in the urinary tract)
2. invasion or crossing epithelial barriers
3. evasion of host defense system through inhibition of
   - phagocytic uptake via polysaccharide capsule (e.g. S. pneumoniae, N. meningitidis, H. influenzae) or surface proteins (e.g. Staphylococcus, Streptococcus)
4. toxin production
   - exotoxins are secreted by living pathogenic bacteria and cause disease even if the bacteria is not present (e.g. Clostridium)
   - endotoxins are structural components of GN bacterial cell walls, and may be shed by live cells or released during cell lysis
5. intracellular growth
   - obligate intracellular: Rickettsia, Chlamydia, Chlamydia phila
   - facultative intracellular: Salmonella, Neisseria, Brucella, Mycobacteria, Listeria, Legionella
6. biofilm
   - an extracellular polysaccharide network forming mesh around the bacteria (e.g. S. epidermidis) which can coat prosthetic devices such as IV catheters

### Figure 2. Laboratory identification of bacterial species
Virology

Viral Basics
- Viruses are infectious particles consisting of RNA or DNA covered by a protein coat
  - Infect cells and use host metabolic machinery to replicate
  - Nucleic acid can be double stranded (ds) or single stranded (ss)
  - Can be enveloped or naked
- Virions are mature virus particles that can be released into the extracellular environment
- Host susceptibility is governed by the host cell and virus surface proteins (viral tropism) and cellular immunity

Viral Disease Patterns
1. Acute infections (e.g., adenovirus)
   - Host cells are lysed in the process of virion release
   - Some produce acute infections with late sequelae (e.g., measles virus induces subacute sclerosing panencephalitis)
2. Chronic infections (>6 mo): (e.g., HBV, HIV)
   - Host cell machinery is used to produce and chronically release virions
3. Latent infections
   - Viral genome remains latent in host cell nucleus
   - Can reactivate (e.g., HSV, VZV)

Mycology

Fungal Basics
• fungi are eukaryotic organisms, they can have the following morphologies
  1. yeast (unicellular)
  2. moulds, also known as filamentous fungi (multicellular with hyphae)
  3. dimorphic fungi (found as mould at room temperature but grow as yeast-like forms at body temperature)

<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>Membrane Sterol</td>
</tr>
<tr>
<td>-----------------</td>
</tr>
<tr>
<td>Bacteria</td>
</tr>
<tr>
<td>Human Cell</td>
</tr>
<tr>
<td>Fungi</td>
</tr>
</tbody>
</table>

Mechanisms of Fungal Disease
• primary fungal infection by
  ■ overgrowth of normal flora (e.g. Candida species)
  ■ inhalation of fungal spores
  ■ traumatic inoculation into skin
• toxins produced by fungi (e.g. ingestion aflatoxins)
  ■ allergic reactions to fungi (e.g. bronchopulmonary aspergillosis)

Parasitology

Parasite Basics
• parasite: an organism that lives in or on another organism (host) and damages the host in the process
  ■ parasites with complex life cycles require more than one host to reproduce
    ■ reservoir host: maintains a parasite and may be the source for human infection
    ■ intermediate host: maintains the asexual stage of a parasite or allows development of the parasite to proceed through the larval stages
    ■ definitive host: allows the parasite to develop to the adult stage where reproduction occurs
• 2 major groups of parasites: protozoa and helminths
  ■ see Tables 26 and 27 for examples of clinically important parasites

<table>
<thead>
<tr>

<tr>
<td>Eosinophilia unusual</td>
</tr>
<tr>
<td>Indefinite life span</td>
</tr>
</tbody>
</table>

*Adult Ascaris (roundworm) does not cause eosinophilia; migratory larval phases of Ascaris, however, cause high-grade eosinophilia

Characteristics of Parasitic Disease
• symptoms are usually proportional to parasite burden
• tissue damage is due to the parasite and host immune response
• chronic infections may occur with or without overt disease
• immunocompromised hosts are more susceptible to manifestations of infection, reactivation of latent infections, and more severe disease
• eosinophilia may suggest a parasitic infection

Mechanisms of Parasitic Disease
1. mechanical obstruction (e.g. ascariasis, clonorchiasis)
2. competition with host for resources (e.g. anemia in hookworm disease, vitamin B12 deficiency in diphyllobothriasis)
3. cytotoxicity leading to abscesses and ulcers (e.g. amoebiasis, leishmaniasis)
4. inflammatory
  ■ acute hypersensitivity (e.g. pneumonitis in Loeffler's syndrome)
  ■ delayed hypersensitivity (e.g. egg granulomas in schistosomiasis)
  ■ cytokine-mediated (systemic illness of malaria, disseminated strongyloidiasis)
5. immune-mediated injury
  ■ autoimmune (e.g. myocarditis of Chagas disease, tissue destruction of mucocutaneous leishmaniasis)
  ■ immune complex (e.g. nephritis of malaria, schistosomiasis)
Transmission of Infectious Diseases

Nosocomial Infections

- **Definition:** Infections acquired >48 h after admission to a healthcare facility OR within 30 d from discharge risk factors: prolonged hospital stay, antibiotic use, surgery, hemodialysis, intensive care, colonization with a resistant organism, immunodeficiency
- Patients with nosocomial infections have higher mortality, longer hospital stays, and higher healthcare costs
- Hand hygiene is an essential precaution

*Use of contact precautions for VRE varies depending on institutional policies.
**Not available in Canada
Respiratory Infections

Pneumonia

- see Pediatrics, P80

Definition
- infection of the lung parenchyma

Etiology and Risk Factors
- impaired lung defenses
  - poor cough/gag reflex (e.g. illness, drug-induced)
  - impaired mucociliary transport (e.g. smoking, cystic fibrosis)
  - immunosuppression (e.g. steroids, chemotherapy, AIDS/HIV, DM, transplant, cancer)
- increased risk of aspiration
- impaired swallowing mechanism (e.g. impaired consciousness, neurologic illness causing dysphagia, mechanical obstruction)
- no organ sm identified in 75% of hospitalized cases, and >90% of ambulatory cases

*See Pediatrics, P91, Table for Common Causes and Treatment of Pneumonia at Different Ages

Clinical Presentation
- cough (± sputum), fever, pleuritic chest pain, dyspnea, tachypnea, tachycardia
- elderly often present atypically; altered LOC sometimes the only sign
- evidence of consolidation (dullness to percussion, bronchial breath sounds, crackles)
- features of parapneumonic effusion (decreased air entry, dullness to percussion)
- complications: ARDS, lung abscess, parapneumonic effusion/empyema, pleuritis ± hemorrhage

Investigations
- pulse oximetry to assess severity of respiratory distress
- CBC and differential, electrolytes, urea, Cr, ABG (if respiratory distress), troponin/CK, LFTs, urinalysis
- sputum Gram stain/C&S, blood C&S, ± serology/viral detection, ± pleural fluid C&S (if effusion >5 cm or respiratory distress)
- CXR±CT chest shows distribution (lobar consolidation or interstitial pattern), extent of infiltrate ± cavitation
- bronchoscopy ± washings for:
  - (1) severely ill patients refractory to treatment and (2) immunocompromised patients

Treatment
- ABC, O2, IV fluids, consider salbutamol (nebulized or MDI)
- determine prognosis and need for hospitalization and antibiotics

Criteria for Hospitalization

*Not available in Canada

| Study: Systematic review of articles assessing the sensitivity and specificity of clinical exam maneuvers for the diagnosis of adult community-acquired pneumonia. Results: The presence of fever or immunosuppression had a positive likelihood ratio (LR) of 2, while a history of diabetes had an LR of 3; however, these traits are not confirmatory. The presence of an abnormality in any vital sign, including tachycardia, tachypnea, or fever had a +LR ranging from 2-4, which was not significantly affected by different cut-points. The absence of vital sign abnormality had a -LR ranging from 0.5-0.8. The combination of respiratory rate <30/min, heart rate <100/min, and temperature <37.8°C had a -LR of 0.18. Findings on chest exam raised the likelihood of diagnosis, but were uncommonly seen in studies. For example, presence of asymmetric breath sounds essentially confirmed the diagnosis, but was only present in 4% of patients. In patients with a clinical diagnosis, but normal radiographs, only ~10% will develop radiographic findings in 72 h. |

**Prevention**

- Public Health Agency of Canada recommends the following:
  - Vaccine for influenza A and B annually for all ages ≥ 6 mo
  - Pneumococcal polysaccharide vaccine (Pneumovax®) for all adults >65 yr and in younger patients 24 mo of age and older at high risk for invasive pneumococcal disease (e.g. functional or anatomic asplenia, congenital or acquired immunodeficiency)
  - Pneumococcal conjugate vaccine (Prevnar-13®) for all children ≤5 yr, and for children and adolescents at high risk for invasive pneumococcal disease who are 5-17 yr and who have not previously received Prevnar-13 (CDC recommends giving Prevnar-13 to all adults at high risk for invasive pneumococcal disease)
Influenza

Definitions and Etiology
- influenza viruses A and B
- influenza A further divided into subtypes based on envelope glycoproteins
  - hemagglutinin (H) and neuraminidase (N)
- seasonal (epidemic) influenza
  - main circulating influenza viruses: influenza A (H1N1), influenza A (H3N2) and influenza B
  - associated with antigenic drift (gradual, minor changes due to random point mutations)
  - may create a new viral subtype resulting in a seasonal epidemic (disease prevalence is greater than expected)
  - outbreaks occur mainly during winter months (late December to early March)
- pandemic influenza
  - associated with antigenic shift: abrupt, major changes due to mixing of two different viral strains from different hosts
  - may create a new viral strain resulting in a pandemic outbreak (worldwide)
  - antigenic shift occurs only in type A
- transmission: droplet, possibly airborne

</tbody>
</table>

Clinical Presentation
- incubation period 1-4 d and symptoms typically resolve in 7-10 days
- acute onset of systemic (fever, chills, myalgias, arthralgias, H/A, fatigue) and respiratory symptoms (cough, dyspnea, pharyngitis)
- complications: respiratory (viral pneumonia, secondary bacterial pneumonia, otitis media, sinusitis), muscular (rhabdomyolysis, myositis), neurologic (encephalitis, meningitis, transverse myelitis, Guillain-Barré syndrome)
- severe disease more likely in the elderly, children, pregnant women, patients with immunocompromise, asthma, COPD, CVD, diabetes and obesity

Investigations
- diagnosis is primarily clinical based on symptoms during the influenza season
- nasopharyngeal swabs for RT-PCR (gold standard), or rapid antigen detection (DFA, direct fluorescent antigen) detection
- serology: rarely used for clinical management

Treatment and Prevention
- primarily supportive unless severe infection or high-risk of complications
- neuraminidase inhibitors: zanamivir (Relenza®) and oseltamivir (Tamiflu®) for treatment and prophylaxis against types A and B
  - decreases duration (by ~1 d) and severity of symptoms if given within 48 h of onset
  - treatment beyond 48 h time window may be warranted in immunosuppressed and critically ill patients
- vaccine for influenza A and B viruses is recommended annually for all ages ≥ 6 mo
  - vaccine is reformulated each year to reflect circulating influenza A and B strains

Beware! Do Not Confuse H. influenzae with Influenza Virus
H. influenzae: a bacterium (Types A, B, C, D, E; F, refer to capsule)
Influenza: a virus (Types A and B refer to strain)
Skin and Soft Tissue Infections

Cellulitis

Definition
• acute infection of the skin principally involving the dermis and subcutaneous tissue

Etiology
• common causative agents: S. aureus, β-hemolytic streptococci
• immunocompromised patients or water exposure: may also include GN rods and fungi
• risk factors
  ■ trauma with direct inoculation, recent surgery
  ■ peripheral vascular disease, lymphedema DM, cracked skin in feet/toes (tinea pedis)

Clinical Presentation
• pain, edema, erythema with indistinct borders ± regional lymphadenopathy, systemic symptoms (fevers, chills, malaise)
• can lead to ascending lymphangitis (visible red streaking in skin along lymphatics proximal to area of cellulitis)

Investigations
• CBC and differential, blood C&S if febrile
• skin swab ONLY if open wound with pus

Treatment
• antibiotics: cephalexin (broader coverage if risk factors for GN rods)
• if extensive erythema or systemic symptoms, consider cefazolin IV
• if MRSA is suspected, alternative therapy should be prescribed (see A Simplified Look at Antibiotics, ID47)
• limb rest and elevation may help reduce swelling

Necrotizing Fasciitis

Definition
• life- and limb-threatening infection of the deep fascia characterized by rapid spread

Etiology
two main forms
• Type I: polymicrobial infection – aerobes and anaerobes (e.g. S. aureus, Bacteroides, Enterobacteriaceae)
• Type II: monomicrobial infection with GAS, and less commonly S. aureus

Clinical Presentation
• pain out of proportion to clinical findings and beyond border of erythema
• edema, ± crepitus (subcutaneous gas from anaerobes), ± fever
• infection spreads rapidly
• patients may rapidly become very sick (tachycardia, hypotension, lightheadedness)
• late findings
  ■ skin turns dusky blue and black (secondary to thrombosis and necrosis)
  ■ induration, formation of hemorrhagic bullae

Investigations
• clinical/surgical diagnosis – do NOT wait for results of investigations before beginning treatment
• blood and tissue C&S
• serum CK (elevated CK usually means myonecrosis – a late sign)
• plain film x-ray (soft tissue gas may be visualized)
• surgical exploration for debridement of infected tissue

Treatment
• resuscitation with IV fluids
• emergency surgical debridement to confirm diagnosis and remove necrotic tissue (may require amputation)
• IV antibiotics
  ■ unknown organism: meropenem or piperacillin/tazobactam + clindamycin IV ± vancomycin if MRSA is considered
  ■ Type I (polymicrobial): piperacillin/tazobactam + clindamycin IV
  ■ Type II (monomicrobial): cefazolin (or cloxacillin) + clindamycin IV; with confirmed GAS infection, penicillin G + clindamycin IV
  ■ with Type II, evaluate for streptococcal toxic shock syndrome and the need for IV Ig
Gastrointestinal Infections

Acute Diarrhea

- see Gastroenterology, G15 and Pediatrics, P34

Epidemiology
- one of the top five leading causes of death worldwide, according to the World Health Organization
- significant morbidity in developed countries (over 900,000 hospitalizations in the United States each year)

Definition
- passage of ≥3 loose or liquid stools/d OR >200 g stool/d for >2 d but ≤14 d

Approach to Acute Diarrhea
- rationale
  - the vast majority of acute diarrhea is caused by infection
  - in most cases, acute diarrheal illness is viral and/or self-limited, and lasts <3 d
  - investigations are costly and are necessary only in certain circumstances
- therefore the evaluation of acute diarrhea involves
  - identifying characteristics of the illness or patient that warrant further investigation
  - assessing volume status to determine appropriate method of rehydration

Physical Exam
- volume status: appearance, level of alertness, pulse, BP, orthostatic vitals, JVP, mucous membranes, skin turgor, capillary refill
- abdominal exam: pain, guarding, peritoneal signs

Treatment
- rehydration is mainstay of treatment
  - oral rehydration therapy
  - IV rehydration if oral intake insufficient to replace fluid loss
  - antidiarrheal agents reduce duration of diarrhea: loperamide, bismuth salicylate
    - delays excretion of causative pathogens
  - contraindications: diarrhea with fever, bloody stool or diarrhea caused by C. difficile
- antibiotic therapy is rarely indicated because:
  - most acute diarrheal illness is viral and self-limited
  - antibiotics can eradicate normal gut flora, predisposing patient to C. difficile infection
  - antibiotics prolong the shedding of Salmonella and other causes of bacterial diarrhea
  - in EHEC infection, antibiotics may increase the risk of HUS

Initial Assessment

Any of:
- fever
- blood in stool
- severe abdominal pain ± peritoneal signs
- profuse diarrhea with signs of hypovolemia
- hospitalized or recent use of antibiotics
- age ≥65 yr with comorbidities
- immunocompromised (chemotherapy, HIV)
- diarrhea >7 d in duration
- exposure to suspicious foods or untreated water
- sexual contacts: MSM

Investigations

Routine Tests:
- Stool C&S for EHEC, stool for Shiga toxin
- Stool C&S for Campylobacter, Salmonella, and Shigella

Special Tests
- Stool C&S for EHEC, stool for Shiga toxin A and B
- Stool O&P for Giardia, Cryptosporidium, E. histolytica

Indication

Blood in stool

Recent use of antibiotics or hospitalized

Age ≥65 yr with comorbidities

Immunocompromised

Diarrhea >7 d

Exposure to untreated water

HIV

MSM

Indications for Antimicrobial Therapy

Absolute Indications:
- infection with S. typhi, Shigella, C. difficile, Cryptosporidium, E. histolytica
- immunocompromised patients

Relative Indications:
- infection with V. cholerae, non-typhoid Salmonella, Campylobacter, Yersinia, Giardia, ETEC
- decision to treat is determined by severity of illness (see Tables 13 and 14 for information on common pathogens)

Causes of Acute Bloody Diarrhea

CHES
- Campylobacter
- Hemorrhagic E. coli (e.g., O157:H7)
- Entamoeba histolytica
- Salmonella
- Shigella

Treat Symptoms

Rehydration

Antidiarrheal agents

bismuth salicylate

loperamide

Illness persists

Illness resolves

</table>
Traveller’s Diarrhea

- see Acute Diarrhea, ID11

Epidemiology
- most common illness to affect travellers
- up to 50% of travellers to developing countries affected in first 2 wk and 10-20% after returning home

Etiology
- bacterial (80-90%): E. coli most common (ETEC), Campylobacter, Shigella, Salmonella, Vibrio (non-cholera); wide regional variation (e.g. Campylobacter more common in Southeast Asia)
- viral: norovirus, rotavirus, and astrovirus account for 5-8%
- protozoal (rarely): Giardia, Entamoeba histolytica, Cryptosporidium, and Cyclospora for ~10% in long-term travellers
- pathogen-negative traveller’s diarrhea common despite exhaustive microbiological workup

Treatment
- rehydration is the mainstay of therapy
  - rehydrate with sealed beverages
  - in severe fluid loss, use oral rehydration solutions (1 package in 1 L boiled or treated water)
  - treat symptoms: antidiarrheal agents (e.g. bismuth salicylate, loperamide)
  - empiric antibiotics in moderate or severe illness: ciprofloxacin or azithromycin or rifaximin
  - note: there is increasing fluoroquinolone resistance in causative agents, especially in South and Southeast Asia

Prevention
- proper hygiene practices
  - avoid consumption of: foods or beverages from establishments with unhygienic conditions (e.g. street vendors), raw fruits or vegetables without a peel, raw or undercooked meat and seafood
  - avoid untreated water
  - bismuth salicylate (Pepto-Bismol®): 60% effective (2 tablets qid according to CDC website)
  - CDC Guidelines: antibiotic prophylaxis not recommended
  - increased risk of infection with resistant organisms
  - high risk groups (e.g. immunocompromised) likely to be infected with pathogen not covered by standard antimicrobial agents

Bismuth salicylate (Pepto-Bismol®) can cause patients to have black stools, which may be mistaken for melena
Chronic Diarrhea

• Dukoral®: oral vaccine that offers protection against V. cholerae (efficacy ~80%) and ETEC (efficacy ~50-67%)
  • PHAC recommends that it may be considered for the following situations (not recommended for routine use in travellers):
    - short-term travellers >2 yr old who are high-risk (e.g. chronic illness) for whom there is an increased risk of serious consequences for traveller’s diarrhea (e.g. chronic renal failure, CHF, type 1 DM, inflammatory bowel disease)
    - immunosuppressed
    - history of repeat traveller’s diarrhea
    - increased risk of acquiring traveller’s diarrhea (gastric hypochlorhydria or young children >2 yr),
    - travellers to cholera endemic countries at increased risk of exposure
  • two vaccines against Salmonella typhi are available and their effectiveness is estimated to be between 50-70%

Chronic Diarrhea

• see Gastroenterology, G16

Peptic Ulcer Disease (H. pylori)

• see Gastroenterology, G11

Bone and Joint Infections

Septic Arthritis

Routes of Infection
  • hematogenous
    - contiguous osteomyelitis common in children
  • direct inoculation via skin/trauma
  • iatrogenic (surgery, arthroscopy, arthrocentesis)

Etiology
  • gonococcal
    - N. gonorrhoeae: previously accounted for 75% of septic arthritis in young sexually active adults
  • non-gonococcal
    - S. aureus: affects all ages, rapidly destructive, accounts for most non-gonococcal cases of septic arthritis in adults (especially in those with rheumatoid arthritis)
    - Streptococcus species (Group A and B)
    - Gram-negatives: affect neonates, elderly, IV drug users, immunocompromised
    - S. pneumoniae: affects children
    - Kingella kingae: affects children aged <4 yr of age
    - Haemophilus influenzae type B (Hib) now rare due to Hib vaccine: consider in unvaccinated children
    - Salmonella spp.: characteristic of sickle cell disease
    - coagulase-negative Staphylococcus species: prosthetic joints
  • if culture negative: partially-treated infection (prior to oral antibiotics), reactive arthritis, rheumatic fever, less common bacterial causes such as Borrelia spp. (Lyme disease) or Tropheryma whipplei (Whipple’s disease), and non-infectious causes

Risk Factors
  • gonococcal
    - age (<40 yr), multiple partners, unprotected intercourse, MSM
  • non-gonococcal
    - most affected children are previously healthy with no risk factors: occasionally preceding history of minor trauma
    - bacteremia (extra-articular infection with hematogenous seeding, endocarditis)
    - prosthetic joints/recent joint surgery
    - underlying joint disease (rheumatoid arthritis, osteoarthritis)
    - immunocompromise (DM, chronic kidney disease, alcoholism, cirrhosis)
    - loss of skin integrity (cutaneous ulcer, skin infection)
    - age >80 yr

Clinical Presentation of Gonococcal Arthritis
  • two forms (although often overlap)
    - bacteremic form
    - systemic symptoms: fever, malaise, chills
    - gonococcal triad: migratory polyarthritis, tenosynovitis, dermatitis (pustular skin lesions)
    - septic arthritis form
    - local symptoms in involved joint: swelling, warmth, pain, inability to bear weight, marked decrease in range of motion)
Clinical Presentation of Non-Gonococcal Arthritis

- acute onset of pain, swelling, warmth, decreased range of motion ± fever and chills; in children, refusal to weight bear
- most often in large weight-bearing joints (knee, hip, ankle) and wrists
- usually monoarticular (polyarticular risk factors: rheumatoid arthritis, endocarditis, GBS)

Investigations

- consider rheumatologic causes for monoarthritis (see Rheumatology, RH3)
- gonococcal: blood C&S, as well as endocervical, urethral, rectal, and oropharyngeal testing
- non-gonococcal: blood C&S
- arthrocentesis (synovial fluid analysis) is mandatory: CBC and differential, Gram stain, C&S, examine for crystals
  - infectious = opaque, increased WBCs (>15,000/mm³); likelihood of infection increases with increasing WBCs, PMNs >90%, culture positive
  - growth of N. gonorrhoea from synovial fluid is successful in <50% of cases
  - ± plain x-ray: assess for osteomyelitis, provides baseline to monitor treatment

Treatment

- medical
  - empiric IV antibiotics: specific choice depends on clinical scenario; for most adults, vancomycin + ceftriaxone is reasonable; for fully vaccinated children, cefazolin or cefoxitin IV unless MRSA is a consideration – delay may result in joint destruction
  - Gram stain and cultures guide subsequent treatment
  - gonococcal: ceftriaxone + azithromycin, for concurrent treatment of C. trachomatis
  - non-gonococcal: antibiotics against Streptococcus spp. (2-3 wk IV/PO), S. aureus (4 wk IV minimum), or GNB (4 wk)
  - surgical drainage if (see Orthopedics, OR10)
    - persistent positive joint cultures on repeat arthrocentesis
    - hip joint involvement
    - prosthetic joint
    - daily joint aspirations until culture sterile; no need to give intra-articular antibiotics
    - physiotherapy

Prognosis

- gonococcal: responds well after 24-48 h of initiating antibiotics (usually complete recovery)
- non-gonococcal: in children, generally good outcome if treated promptly; in adults, up to 50% morbidity (decreased joint function/mobility)

Diabetic Foot Infections

Etiology

- neuropathy, peripheral vascular disease, and hyperglycemia contribute to foot ulcers that heal poorly, and are predisposed to infection
- organisms in mild infection: S. aureus, Streptococcus spp.
- organisms in moderate/severe infection: polymicrobial with aerobes (S. aureus, Streptococcus, Enterococcus, GNB) and anaerobes (Peptostreptococcus, Bacteroides, Clostridium)

Clinical Presentation

- not all ulcers are infected
- consider infection if: probe to bone (see below), ulcer present >30 d, recurrent ulcers, trauma, PVD, prior amputation - loss of protective sensation, renal disease, history of walking barefoot
- diagnosis of infected ulcer: ≥2 of the cardinal signs of inflammation (redness, warmth, swelling, pain) OR the presence of pus
- ± crepitis, osteomyelitis, systemic toxicity
- visible bone or probe to bone → osteomyelitis
- infection severity
  - mild = superficial (no bone/joint involvement)
  - moderate = deep (beneath superficial fascia, involving bone/joint) or erythema >2 cm
  - severe = infection in a patient with systemic toxicity (fever, tachypnea, leukocytosis, tachycardia, hypotension)

Investigations

- curettage specimen from ulcer base, aspirate from an abscess or bone biopsy (results from superficial swabs do not represent organisms responsible for deeper infection)
- blood C&S if febrile
- assess for osteomyelitis by x-ray (although not sensitive in early stages) or MRI if high clinical suspicion
  - if initial x-ray normal, repeat 2-4 wk after initiating treatment to increase test sensitivity

Treatment

- evaluate for early surgical debridement ± revascularization or amputation
- eliminate/reduce pressure and provide regular local wound care
- mild: cephalixin or clindamycin

---

Does this Patient with Diabetes have Osteomyelitis of the Lower Extremity? JAMA 2008;299:806-813 Study: Systematic literature review. 21 studies. Population: 1,027 adult patients with DM being investigated for osteomyelitis. Intervention: Various aspects of history, physical exam, laboratory tests, and diagnostic imaging studies versus bone biopsy. Primary Outcome: Diagnostic utility. Results: No studies examined any part of history taking. Temperature, ulcer characteristics (erythema, swelling, purulence), elevated WBC, skin swabs, and soft tissue cultures were not useful. Nuclear imaging has poor specificity for osteomyelitis (62%-88.5%), and MRIs have greater accuracy in detecting osteomyelitis.

*NS = not significant
• moderate: clindamycin + ciprofloxacin or moxifloxacin PO, ceftriaxone or ertapenem IV ± MRSA coverage
• severe: piperacillin/tazobactam or meropenem IV ± vancomycin if MRSA known or suspected
• encourage glycemic control

Osteomyelitis

• see Orthopedics, OR9

Cardiac Infections

Infective Endocarditis

Definition
• infection of cardiac endothelium, most commonly the valves
• classifications: acute vs. subacute, native valve vs. prosthetic valve, right sided vs. left sided
• leaflet vegetations are made of platelet-fibrin thrombi, WBCs, and bacteria

Risk Factors and Etiology
• predisposing conditions
  • high risk: prosthetic cardiac valve, previous IE, congenital heart disease (unrepaired, repaired within 6 mo, repaired with defects), cardiac transplant with valve disease (surgically constructed systemic-to-pulmonary shunts or conduits)
  • moderate risk: other congenital cardiac defects, acquired valvular dysfunction, hypertrophic cardiomyopathy
  • low/no risk: secundum ASD or surgically repaired ASD < VSD, PDA, MV prolapse, ischemic heart disease, previous CABBG
• opportunity for bacteremia: IVDU, indwelling venous catheter, hemodialysis, poor dentition, DM, HIV
• frequency of valve involvement MV >> AV > TV > PV
  • but in 50% of IVDU related IE the tricuspid valve is involved

Organisms in bold are the most common isolates
1. Streptococcus includes mainly viridans group streptococci
2. Other includes less common organisms such as:
  • Streptococcus galalactiae (previously known as S. bovis; usually associated with underlying GI malignancy, cirrhosis)
  • Culture-negative organisms including nutritionally-deficient streptococci; HACEK, Bartonella, Coxiella, Chlamydia, Legionella, Brucella
  • Candida
3. IVDU endocarditis pathogens depend on substance used to dilute the drugs (i.e. tap water = Pseudomonas, saliva = oral flora, toilet water = GI flora)

Clinical Presentation
• systemic
  • fever (80-90%), chills, weakness, rigors, night sweats, weight loss, anorexia
• cardiac
  • dyspnea, chest pain, clubbing (subacute)
  • regurgitant murmur (new onset or increased intensity)
  • signs of CHF (secondary to acute MR, AR)
• embolic/vascular
  • petechiae over legs, splinter hemorrhages (linear, reddish-brown lesion within nail bed)
  • Janeway lesions (painless, 5 mm, erythematous, hemorrhagic pustular lesions on soles/palms)
  • focal neurological signs (CNS emboli), H/A (mycotic aneurysm)
  • splenomegaly (subacute)
  • microscopic hematuria, flank pain (renal emboli) ± active sediment
• immune complex
  • Osler’s nodes (painful, raised, red/brown, 3-15 mm on digits)
  • glomerulonephritis
  • arthritis
  • Roth’s spots (retinal hemorrhage with pale centre)

Diagnosis
• Modified Duke Criteria
  • definitive diagnosis if: 2 major, OR 1 major + 3 minor, OR 5 minor
  • possible diagnosis if: 1 major + 1 minor, OR 3 minor
Table 17. Modified Duke Criteria

**Major Criteria (2)**

1. Positive blood cultures for IE
   - Typical microorganisms for IE from 2 separate blood cultures (Streptococcus viridans, HACEK group, Staphylococcus gallolyticus (previously known as S. bovis), Staphylococcus aureus, community-acquired enterococci) OR Persistently positive blood culture, defined as recovery of a microorganism consistent with IE from blood drawn >12 h apart OR
   - All of 3 or a majority of 4 or more separate blood cultures with first and last drawn >1 h apart OR
   - Single positive blood culture for Coxiella burnetii or antiphase I IgG antibody titer >1:800

2. Evidence of endocardial involvement
   - Positive echocardiogram for IE (oscillating intracardiac mass on valve or supporting structures, or in the path of regurgitant jets, or on implanted material in the absence of an alternative anatomic explanation OR abscess OR new partial dehiscence of prosthetic valve) OR
   - New valvular regurgitation (insufficient if increase or change in preexisting murmur)

**Minor Criteria (5)**

1. Predisposing condition (abnormal heart valve, IVDU)
2. Fever (38.0°C/100.4°F)
3. Vascular phenomena: major arterial emboli, septic pulmonary infarcts, mycotic aneurysms, ICH, conjunctival hemorrhages, Janeway lesions
4. Immunologic phenomena: glomerulonephritis, rheumatoid factor, Osler’s nodes, Roth’s spots
5. Positive blood culture but not meeting major criteria OR serologic evidence of active infection with organism consistent with IE

**Investigations**

- serial blood cultures: 3 sets (each containing one aerobic and one anaerobic sample) collected from different sites >1 h apart
  - persistent bacteremia is the hallmark of endovascular infection (such as IE)
- repeat blood cultures (at least 2 sets) after 48-72 h of appropriate antibiotics to confirm clearance
- blood work: CBC and differential (normochromic, normocytic anemia), ESR (increased), RF (+), BUN/Cr
- urinalysis (proteinuria, hematuria, red cell casts) and urine C&S
- ECG: prolonged PR interval may indicate perivalvular abscess
- echo findings: vegetations, regurgitation, abscess
  - TTE (poor sensitivity) inadequate in 20% (obesity, COPD, chest wall deformities)
  - TEE indicated if TTE is non-diagnostic in patients with at least possible endocarditis or if suspect prosthetic valve endocarditis or complicated endocarditis (e.g. paravalvular abscess/perforation) (~90% sensitivity)

**Treatment**

- medical
  - usually non-urgent and can wait for confirmation of etiology before initiating treatment
  - empiric antibiotic therapy if patient is unstable; administer ONLY after blood cultures have been taken
    - first line empiric treatment for native valve: vancomycin + gentamicin OR ceftriaxone
    - first line empiric treatment for prosthetic valve: vancomycin + gentamicin + cefepime + rifampin
  - targeted antibiotic therapy: antibiotic and duration (usually 4-6 wk) adjusted based on valve, organism, and sensitivities
  - monitor for complications of IE (e.g. CHF, conduction block, new emboli) and complications of antibiotics (e.g. interstitial nephritis)
  - prophylaxis only for high risk individuals listed above with dental procedures that may lead to bleeding OR invasive procedure of the respiratory tract that involves incision or biopsy of the respiratory mucosa, such as tonsillectomy and adenoidectomy OR procedures on infected skin, skin structure, or musculoskeletal tissue
    - dental/respiratory: amoxicillin single dose 30-60 min prior; clindamycin if penicillin-allergic
    - skin/soft tissue: cephalexin single dose 30-60 min prior; clindamycin if penicillin-allergic
      (modify based on etiology of skin/soft tissue infection)
  - surgical
    - most common indication is refractory CHF
    - other indications include: valve ring abscess, fungal etiology, valve perforation, unstable prosthesis, ≥2 major emboli, antimicrobial failure (persistently positive blood cultures), mycotic aneurysm, Staphylococci on a prosthetic valve

**Prognosis**

- adverse prognostic factors: CHF, prosthetic valve infection, valvular/myocardial abscess, embolization, persistent bacteremia, altered mental status
- mortality: prosthetic valve IE (25-50%), non-IVDU S. aureus IE (30-45%) IVDU S. aureus or streptococcal IE (10-15%)
CNS Infections

Meningitis

- see Pediatrics, P54

**Definition**
- inflammation of the meninges

</table>

**Risk Factors**
- lack of immunization against H. influenzae type b, S. pneumoniae, and N. meningitidis in children
- most cases of bacterial meningitis are due to hematogenous spread from a mucosal surface (nasopharynx)
- direct extension from a parameningeval focus (otitis media, sinusitis) less common
- penetrating head trauma
- anatomical meningeal defects – CSF leaks
- previous neurosurgical procedures, shunts
- immunodeficiency (corticosteroids, HIV, asplenia, hypogammaglobulinemia, complement deficiency)
- contact with colonized or infected persons

**Clinical Presentation**
- neonates and children: fever, lethargy, irritability, vomiting, poor feeding
- older children and adults: fever, H/A, neck stiffness, confusion, lethargy, altered level of consciousness, seizures focal neurological signs, N/V, photophobia, papilledema
- petechial rash in meningococcal meningitis, seen more frequently on trunk or lower extremities

**Investigations**
- blood work: CBC and differential, electrolytes (for SIADH), blood C&S
  - CSF: opening pressure, cell count + differential, glucose, protein, Gram stain, bacterial C&S
  - AFB, fungal C&S, cryptococcal antigen in immunocompromised patients, subacute illness, suggestive travel history or TB exposure
  - PCR for HSV, VZV, enteroviruses; in infants <6 mo, parechoviruses
  - WNV serology in blood and CSF during summer and early fall if viral cause suspected
- imaging/neurologic studies: CT, MRI, EEG if focal neurological signs present

**Treatment**
- bacterial meningitis is a medical emergency: do not delay antibiotics for CT or LP
  - empiric antibiotic therapy
    - age ≤28 days: ampicillin + cefotaxime
    - age 29 days-3 mo: cefotaxime + vancomycin
    - age >3 mo: ceftriaxone + vancomycin
    - add ampicillin IV if risk factors for infection with L. monocytogenes present: age >50, alcoholism, immunocompromised
    - steroids in acute bacterial meningitis: dexamethasone IV within 20 min prior to or with first dose of antibiotics
    - continue in those patients with proven pneumococcal meningitis
    - not recommended for patients with suspected bacterial meningitis in some resource-limited countries
    - not recommended for neonatal meningitis

**Table 18. Common Organisms in Meningitis**

**Table 19. Typical CSF Profiles for Meningitis**

**CSF Analysis**
- Glucose (mmol/L)
  - Decreased
  - Normal
- Protein (g/L)
  - Markedly Increased
  - Increased
- WBC
  - 500-10,000/μL
  - 10-500/μL
- Predominant WBC
  - Neutrophils
  - Lymphocytes

**Results**

| Study | Sensitive Clinical Exams: Data were heterogeneous, and lacked standardization of clinical exams. No single item on clinical history or physical exam was sufficient to rule out meningitis, including Kernig’s and Brudzinski’s signs, or the absence of the classic triad of fever, neck stiffness, and altered mental status (AUC=0.85). Jolt accentuation had a sensitivity of 87%.
| Study | Conclusions: Data were heterogeneous, and lacked standardization of clinical exams. No single item on clinical history or physical exam was sufficient to rule out meningitis, including Kernig’s and Brudzinski’s signs, or the absence of the classic triad of fever, neck stiffness, and altered mental status. Jolt accentuation has high sensitivity, but further research is needed. LP may be performed safely without CT head in patients without altered LOC, no recent seizure, no history of CNS disease, not immunocompromised, and <60 yr.

Brudzinski’s Sign
- Passive neck flexion causes involuntary flexion of hips and knees

Kernig’s Sign
- Resistance to knee extension when hip is flexed to 90°

Jolt Accentuation of H/A
- Headache worsens when head turned horizontally at 2-3 rotations; more sensitive than Brudzinski’s and Kernig’s

CSF Gram Stain Findings
- S. pneumoniae – GP diplococci
- N. meningitidis – GN diplococci
- H. influenzae – Pleomorphic GN cocccobacilli
- L. monocytogenes – GP rods

Does this Adult Patient Have Acute Meningitis? From The Rational Clinical Examination
- JAMA 2009: http://www.jamaevidence.com/content/109/2/295
- Study: Systematic review of articles assessing the sensitivity and specificity of clinical exam maneuvers for the diagnosis of adult meningitis.
- Results: In retrospective studies, sensitivity for headache was 69%, and 52% for nausea and vomiting. Sensitivity for physical exam findings is similarly low (fever: 87%, neck stiffness: 80%, altered mental status: 69%). Sensitivity for the combination of the classic triad of fever, neck stiffness, and altered mental status was 45%.
- In prospective studies, sensitivity of H/A was 92% while sensitivity of N/V could not be pooled, and ranged from 32-70%. Brudzinski’s and Kernig’s signs had a sensitivity of 5% and Kernig’s sign only 5-9%. Jolt accentuation had a sensitivity of 87%.
- Conclusions: Data were heterogeneous, and lacked standardization of clinical exams. No single item on clinical history or physical exam was sufficient to rule out meningitis, including Kernig’s and Brudzinski’s signs, or the absence of the classic triad of fever, neck stiffness, and altered mental status. Jolt accentuation has high sensitivity, but further research is needed. LP may be performed safely without CT head in patients without altered LOC, no recent seizure, no history of CNS disease, not immunocompromised, and <60 yr.
Prevention
- see Pediatrics, P54
- immunization
  - child: immunization against *H. influenzae* type B (Pentacel®), *S. pneumoniae* (Synflorix®, Prevenar-13®), *N. meningitidis* (Menjugate®, Menactra®, Nimenrix®, Menveo®, Bexzero®)
  - adults: immunization against *N. meningitidis* in selected circumstances (outbreaks, travel, epidemics) and *S. pneumoniae* (Pneumovax®) for high-risk groups
- prophylaxis: close contacts of patients infected with *H. influenzae* type B should be treated with rifampin if they live with an inadequately immunized (<4 yr) or immunocompromised child (<18 yr); ciprofloxacin, rifampin, or ceftriaxone if close or household contact of a patient with *N. meningitidis*; meningococcal vaccines are also recommended for post-exposure prophylaxis for close contacts and in outbreak control

Prognosis
- complications
  - H/A, seizures, cerebral edema, hydrocephalus, SIADH, residual neurological deficit (especially CN VIII), deafness, death
- mortality
  - *S. pneumoniae* 25%; *N. meningitidis* 5-10%; *H. influenzae* 5%
  - worse prognosis if: extremes of age, delays in diagnosis and treatment, stupor or coma, seizures, focal neurological signs, septic shock at presentation

**Encephalitis**

Definition
- inflammation of the brain parenchyma

Etiology
- identified in only 40-70% of cases
  - when cause is identified, the most common etiology is viral: HSV, VZV, EBV, CMV, enteroviruses, parechoviruses, West Nile and other arboviruses, influenza and other respiratory viruses, HIV, mumps, measles, rubies, polio
  - bacteria: *L. monocytogenes*, *mycobacteria*, spirochetes (Lyme, syphilis), *Mycoplasma pneumoniae*
  - parasites: protozoa (e.g. *Toxoplasma*) and helminths (rare)
  - fungi: e.g. *Cryptococcus*
  - post-infectious (e.g. acute disseminated encephalomyelitis [ADEM])
  - auto-antibody mediated encephalitis
  - anti-N-methyl-D-aspartate (NMDA) receptor encephalitis most common
  - in adults, most autoantibody-mediated encephalitis cases are associated with malignancy

Pathophysiology
- acute inflammatory disease of the brain due to direct invasion or pathogen-initiated immune response
- viruses may reach the CNS via peripheral nerves (e.g. rubies, HSV)
- herpes simplex encephalitis
  - acute, necrotizing, asymmetrical hemorrhagic process with lymphocytic and plasma cell reaction which usually involves the medial temporal and inferior frontal lobes
  - associated with HSV-1, but can also be caused by HSV-2
- influenza and other respiratory viruses are associated with acute necrotizing encephalopathy (ANE); likely mediated by pathogen-initiated immune response

Clinical Presentation
- constitutional: fever, chills, malaise, N/V
- meningeal involvement (meningoencephalitis): H/A, nuchal rigidity
- parenchymal involvement: seizures, altered mental status focal neurological signs
- herpes simplex encephalitis
  - acute onset (<1 wk) of focal neurological signs: hemiparesis, ataxia, aphasia, focal or generalized seizures
  - temporal lobe involvement: behavioural disturbance
  - usually rapidly progressive over several days and may result in coma or death
  - common sequelae: memory and behavioural disturbances

Investigations
- CSF: opening pressure, cell count and differential, glucose, protein, Gram stain, bacterial C&S, PCR for HSV, VZV, EBV, enteroviruses/parechoviruses, *M. pneumoniae*, and selectively for other less common etiologies
- serology: may aid diagnosis of certain causes of encephalitis (e.g. EBV, West Nile virus, rubies, *Bartonella henselae*)
- imaging/neurologic studies: CT, MRI, EEG to define anatomical sites affected
- invasive testing: brain tissue biopsy may be required for culture histological examination, and immunocytotoxicity (if diagnosis not clear via non-invasive means)
- findings in herpes simplex encephalitis (must rule out due to high mortality)
  - CT/MRI: medial temporal lobe necrosis
  - EEG: early focal slowing, periodic discharges
**CNS Infections**

**Treatment**
- general supportive care
- monitor vital signs carefully
- IV acyclovir empirically until HSV encephalitis ruled out

---

**Generalized Tetanus**

- see Pediatrics, P4

**Etiology and Pathophysiology**
- caused by *Clostridium tetani*: motile, spore forming, anaerobic GP bacillus
- found in soil, splinters, rusty nails, GI tract (humans and animals)
- traumatic implantation of spores into tissues with low oxygenation (e.g. puncture wounds, burns, nonsterile surgeries or deliveries)
- upon inoculation, spores transform into *C. tetani* bacilli that produce tetanus toxin
  - toxin travels via retrograde axonal transport to the CNS where it irreversibly binds presynaptic neurons to prevent the release of inhibitory neurotransmitters (e.g. GABA)
  - net effect is the disinhibition of spinal motor reflexes which results in tetany and autonomic hyperactivity

**Clinical Presentation**
- generalized tetanus
  - initially present with painful spasms of masseters (trismus or "lockjaw")
  - sustained contraction of skeletal muscle with periodic painful muscle spasms (triggered by sensory stimuli, e.g. loud noises)
  - paralysis descends to involve large muscle groups (neck, abdomen)
  - apnea, respiratory failure, and death secondary to tonic contraction of pharyngeal and respiratory muscles
- autonomic hyperactivity
  - diaphoresis, tachycardia, HTN, fever as illness progresses

**Investigations**
- primarily a clinical diagnosis, often although not always with a history of a traumatic wound and lack of immunization
- culture wounds, CK may be elevated

**Treatment**
- stop toxin production
  - wound debridement to clear necrotic tissue and spores
  - antimicrobial therapy: IV metronidazole; IV penicillin G is an effective alternative
  - neutralize unbound toxin with tetanus immune globulin (TIG)
  - supportive therapy: intubation, spasmyloytic medications (benzodiazepines), quiet environment, cooling blanket
  - control autonomic dysfunction: α- and β-blockade (e.g. labetalol), magnesium sulfate

**Prevention**
- infection with *C. tetani* does not produce immunity – vaccinate patients on diagnosis
- tetanus toxoid vaccination (see Pediatrics, P4 and Emergency Medicine, ER17)

---

**Rabies**

**Definition**
- acute progressive encephalitis caused by RNA virus (genus *Lyssavirus* of the Rhabdoviridae family)

**Etiology and Pathophysiology**
- any mammal can transmit the rabies virus
  - most commonly transmitted by raccoon, skunk, bat, fox, cat, and dog; monkeys also a risk in the developing world
  - transmission: breach of skin by teeth or direct contact of infectious tissue (saliva, neural tissue) with skin or mucous membranes
  - almost all cases due to bites
  - virus travels via retrograde axonal transport from PNS to CNS
  - virus multiplies rapidly in brain, then spreads to other organs, including salivary glands
  - development of clinical signs occurs simultaneously with excretion of rabies virus in saliva
  - infected animal can transmit rabies virus as soon as it shows signs of disease

**Clinical Presentation**
- five stages of disease
  - 1. incubation period
    - 1-3 mo on average (can range from days to years)
2. prodrome (<1 wk)
   - influenza-like illness: low-grade fever, malaise, anorexia, N/V, H/A, sore throat
   - pain, pruritus, and paresthesia may occur at wound site
   - once prodromal symptoms develop, there is rapid, irreversible progression to death
     progression from prodrome to coma and death may occur without an intervening acute
     neurologic syndrome

3. acute neurologic syndrome: 2 types (<1 wk)
   a. encephalitic (most common): hyperactivity, fluctuating LOC, hydrophobia, aerophobia
      hypersalivation, fever, seizures
      - painful pharyngeal spasms on encountering gust of air or swallowing water cause aerophobia
      and hydrophobia, respectively
   b. paralytic: quadriplegia, loss of anal sphincter tone, fever

4. coma
   - complete flaccid paralysis, respiratory and cardiovascular failure

5. death (within days to weeks of initial symptoms)

Investigations
- purpose of diagnosis by investigations is to limit patient contact with others and to identify others
  exposed to the infectious source
- ante-mortem: direct immunofluorescence or PCR on multiple specimens: saliva, skin biopsy, serum, CSF
- post-mortem: direct immunofluorescence in nerve tissue, presence of Negri bodies (inclusion bodies in
  neurons)

Treatment
- post-exposure prophylaxis depends on regional prevalence (contact Public Health) and circumstances
  surrounding injury
- 3 general principles
  - wound care: clean wound promptly and thoroughly with soap and running water
  - passive immunization: HRIG infiltrated into wound site, with any remaining volume administered
    IM in anatomical site distant from vaccine administration
  - active immunization: inactivated human diploid cell rabies virus vaccine (series of 4 shots post-
    exposure if not pre-immunized)
- treatment is supportive once victim manifests signs and symptoms of disease

Prevention
- pre-exposure vaccination
  - recommended for high risk persons: laboratory staff working with rabies, veterinarians, animal and
    wildlife control workers, long-term travellers to endemic areas
  - eliminates need for HRIG following an exposure, and reduces number of HDCV PEP shots from 4 to 2

Systemic Infections

Sepsis and Septic Shock

- see Respilology, R34

Definitions
- systemic inflammatory response syndrome (SIRS): 2 or more of
  1. temperature <36°C/96.8°F or >38°C/100.4°F
  2. heart rate >90 beats/min
  3. respiratory rate >20 breaths/min or PaCO2 <32 mmHg
  4. WBC <4 x 10^9/L or >12 x 10^9/L or >10% bands
- sepsis: SIRS + proven or provable infection
- severe sepsis: sepsis + signs of end-organ dysfunction and hypoperfusion
- septic shock: severe sepsis + hypotension (<90 mmHg sBP), despite adequate fluid resuscitation

Pathophysiology
- causative agents are identified in only 50-70% of cases
- when organisms are identified, GP and GN organisms are the cause in 90% of cases
- primary bloodstream infection or secondary bacteraemia → local immune response → immune
  cells release pro-inflammatory cytokines → immune response spreads beyond local environment →
  unregulated, exaggerated systemic immune response → vasodilation and hypotension → involvement
  of tissues remote from the site of injury/infection resulting in multiple major organ dysfunction →
  periodic immunoparalysis

Clinical Presentation
- history: fever, chills, dyspnea, cool extremities, fatigue, malaise, anxiety, confusion
- physical: abnormal vitals (fever, tachypnea, tachycardia, hypotension), local signs of infection
**Systemic Infections**

**Investigations**
- CBC and differential, electrolytes, BUN, creatinine, liver enzymes, ABG, lactate, INR, PTT, FDP, blood C&S x2, urinalysis, urine C&S and cultures of any wounds or lines
- CXR (other imaging depends on suspicion of focus of infection)

**Treatment (see Respirology, R34)**
- respiratory support: O2 ± intubation
- cardiovascular support: IV fluids, ± norepinephrine + ICU
- IV antibiotics (empiric, depends on suspected source)
  - start with broad spectrum antibiotics (piperacillin/tazobactam or meropenem) ± additional agents depending on patient risk factors, suspected etiology of infection, and local microbial susceptibilities (± aminoglycoside for drug-resistant GNs or vancomycin for MRSA)
  - narrow once susceptibilities are known
- hydrocortisone IV in patients with septic shock unresponsive to fluid resuscitation and vasopressors

---

**Leprosy (Hansen’s Disease)**

**Etiology**
- *Mycobacterium leprae*: obligate intracellular bacteria, slow growing (doubling time 12.5 d), survives in macrophages
- bacteria transmitted from nasal secretions, potentially via skin lesions
- invades skin and peripheral nerves leading to chronic granulomatous disease

**Clinical Presentation**
- lesions involve cooler body tissues (e.g. skin, superficial nerves, nose, eyes, larynx)
- spectrum of disease determined by host immune response to infection
  i. paucibacillary “tuberculoid” leprosy (intact cell-mediated immune response)
    - ≤5 hypohesitic lesions, usually hypopigmented, well-defined, dry
    - early nerve involvement, enlarged peripheral nerves, neuropathic pain
  ii. multibacillary “lepromatous” leprosy (weak cell-mediated immune response)
    - ≥6 lesions, symmetrical distribution
    - leonine facies (nodular facial lesions, loss of eyebrows, thickened ear lobes)
    - extensive cutaneous involvement, late and insidious nerve involvement causing sensory loss at the face and extremities
  iii. borderline leprosy
    - lesions and progression lies between tuberculoid and lepromatous forms

**Investigations**
- skin biopsy down to fat or slit skin smears for AFB staining, PCR
- histologic appearance: intracellular bacilli in spherical masses (lepra cells), granulomas involving cutaneous nerves

**Treatment (WHO Treatment Regimens)**
- paucibacillary: dapsone daily + rifampin monthly x 6 mo
- single skin lesion paucibacillary: single dose of rifampin, ofloxacin, and minocycline
- multibacillary: dapsone + rifampin monthly + clofazimine monthly x 12 mo AND low dose clofazimine once daily x 12 mo
- treatment of leprosy can cause an immune reaction to killed or dying bacteria (e.g. erythema nodosum leprosum and reversal reaction): symptomatic management with NSAIDs if mild, prednisone with 6-12 wk taper if severe; thalidomide for erythema nodosum leprosum

**Prognosis**
- curable with WHO-approved treatment regimens
- complications: muscle atrophy, contractures, trauma/superinfection of lesions, crippling/loss of limbs, erythema nodosum leprosum, social stigmatization due to clofazimine hyperpigmentation
- long post-treatment follow-up warranted to monitor for relapse and immune reactions
Lyme Disease

Etiology/Epidemiology
- spirochete bacteria: *Borrelia burgdorferi* (N. America) *B. garinii, B. afzelii* (Europe and Asia)
- transmitted by *Ixodes* tick
- reported in 49 of the 50 U.S. states, but most cases occur in the Northeast, the Midwest, and Northern California
- in Canada, reported in southern and southeastern Quebec, southern and eastern Ontario, southeastern Manitoba, New Brunswick and Nova Scotia, as well as southern British Columbia
- small rodents (mice) serve as primary reservoir, while larger animals (white-tailed deer) serve as hosts for ticks
- human contact usually May-August in fields with low brush near wooded areas
- infection usually requires >36 h tick attachment

Clinical Presentation
- stage 1 (early localized stage: 7-14 d post-bite)
  - malaise, fatigue, H/A, myalgias
  - erythema migrans: expanding, non-pruritic bulls-eye (target) lesions (red with clear centre) on thigh/groin/axilla
- stage 2 (early disseminated stage): weeks post-infection
  - CNS: aseptic meningitis, CN palsies (CN VII palsy), peripheral neuritis
  - cardiac: transient heart block or myocarditis
- stage 3 (late persistent stage: months to years post-infection)
  - may not have preceding history of early stage infection
  - MSK: chronic monoarticular or oligoarticular arthritis
  - acrodermatitis chronica atrophicans (due to *B. afzelii*)
  - neurologic: encephalopathy, meningitis, neuropathy

Investigations
- serology: ELISA, Western blot

Prevention
- use of protective clothing (tuck pants into socks), insect repellent, inspection for ticks and prompt removal of tick
- doxycycline prophylaxis within 72 h of removal of an engorged, *Ixodes scapularis* tick in hyperendemic area (local rate of infection of ticks ≥20%) for patients >8 yr who are not pregnant or lactating

Treatment
- stage 1: doxycycline/amoxicillin/cefuroxime
- stage 2-3: ceftriaxone

Toxic Shock Syndrome

Etiology
- superantigens produced by some strains of *S. aureus* or GAS cause widespread T-cell activation and pro-inflammatory cytokine release (IL-1, IL-6, TNF)
- course of disease is precipitous and leads to acute fever, shock, multiorgan failure
- Staphylococcal TSS involves the production of superantigen TSST-1 (toxic shock syndrome toxin 1)
- Streptococcal TSS involves the production of superantigens SPEA, SPEB, SPEC

Risk Factors
- Staphylococcal: tampon use, nasal packing, wound infections (e.g. postpartum vaginal or Cesarean or other surgical infections)
- Streptococcal: minor trauma, surgical procedures, preceding viral illness (e.g. chickenpox), use of NSAIDs

Clinical Presentation and Investigations
- acute onset
- Staphylococcal TSS
  - T >38.9°C
  - sBP <90 mmHg
  - diffuse erythroderma with subsequent desquamation, especially on palms and soles
  - involvement of 3 or more organ systems: GI (vomiting, diarrhea), muscular (myalgia, increased CK), mucous membranes (hyperemia), renal, hepatic, hematologic (thrombocytopenia), CNS (disorientation)
  - isolation of *S. aureus* is not required for diagnosis (*S. aureus* is rarely recovered from blood in TSS)
• Streptococcal TSS
  • SBP <90 mmHg
  • isolation of GAS from a normally sterile site (e.g. blood, pleural, tissue biopsy, or surgical wound)
  • ≥2 of coagulopathy, liver involvement, ARDS, soft tissue necrosis (necrotizing fasciitis, myositis, gangrene), renal impairment, erythematous macular rash that may desquamate

**Treatment**
- supportive: fluid resuscitation
- Staphylococcal: for methicillin-susceptible *S. aureus*: clindamycin + cloxacillin (IV); for MRSA: clindamycin + vancomycin x 10-14 d
- Streptococcal: IV penicillin and clindamycin and ± IVIg

### Cat Scratch Disease

**Etiology**
- *Bartonella henselae*: intracellular bacteria
- cat-to-human transmission via cat scratch/bite

**Clinical Presentation**
- skin lesion appears 3-10 d post-inoculation
- may be followed by fever, tender regional lymphadenopathy
- in some patients, organism may disseminate causing fever of unknown origin, hepatosplenomegaly, retinitis, encephalopathy
- usually self-limited

**Investigations**
- serology, PCR, lymph node biopsy

**Treatment**
- the disease may be self-limited but treatment is recommended by the Infectious Disease Society of America with a 5 d course of azithromycin for immunocompetent patients with mild to moderate illness
- needle aspiration of painful suppurative lymph nodes may hasten the relief of symptoms
- combination therapy consisting of doxycycline or azithromycin plus rifampin often used for disseminated disease (neuroretinitis, hepatosplenomegaly involvement)

### Rocky Mountain Spotted Fever

**Etiology**
- *Rickettsia rickettsii*: obligate intracellular GN organism
- reservoir hosts: rodents, dogs
- vectors: *Dermacentor* ticks
- organisms cause inflammation of endothelial lining of small blood vessels, leading to small hemorrhages and thrombi
- can cause widespread vasculitis leading to H/A, and CNS changes; can progress to death if treatment is delayed

**Clinical Presentation**
- usually occurs in summer following tick bite
- influenza-like prodrome: acute onset fever, H/A, myalgia, N/V, anorexia
- macular rash appearing on day 2-4 of fever
  - begins on wrists and ankles, then spreads centrally to arms/legs/trunk/palms/soles
  - occasionally “spotless” (10% of patients)

**Investigations**
- skin biopsy and serology (indirect fluorescent antibody test)

**Treatment**
- doxycycline, usually 5-7 d (treat for 3 d after defervescence)

### West Nile Virus

**Epidemiology**
- virus has been detected throughout the United States and much of southern Canada
- overall case-fatality rates in severe cases is ~10%

**Transmission**
- primarily from mosquitoes that have fed on infected birds (crows, blue jays)
- transplacental, blood products (rare), organ transplantation
Clinical Presentation
- Most are asymptomatic.
- Most symptomatic cases are mild (West Nile fever): acute onset of H/A, back pain, myalgia, anorexia, maculopapular rash involving chest, back, arms.
- Severe complications: encephalitis, meningoencephalitis, and acute flaccid paralysis (especially in those >60 yr).

Investigations
- IgM antibody in serum or CSF (cross-reactivity with yellow fever and Japanese encephalitis vaccines, and with dengue fever and St. Louis virus infection); may not reflect current illness as IgM antibody can last for >6 mo.
- Viral isolation by PCR from CSF tissue, blood, and fluids (all have low sensitivity).
- CSF: elevated lymphocytes and protein if CNS involvement.

Treatment and Prevention
- Treatment: supportive.
- Prevention: mosquito repellent (DEET), drain stagnant water, community mosquito control programs.

Syphilis

Etiology
- Treponema pallidum: thick motile spirochetes historically detectable by dark-field microscopy.
- Transmitted sexually, vertically, or parenterally (rare).

Clinical Presentation
- see Dermatology, D31 and Gynecology, GY30.
- Multi-stage disease:
  1. Primary syphilis (3-90 d post infection)
     - Painless chancre at inoculation site (any mucosal surface).
     - Regional lymphadenopathy.
     - Acute disease lasts 3-6 wk, 25% progress to secondary syphilis without treatment.
  2. Secondary syphilis = systemic infection (2-8 wk following chancre)
     - Maculopapular rash involving palms and soles.
     - Generalized lymphadenopathy, low-grade fever, malaise, H/A, aseptic meningitis, ocular/otic syphilis.
     - Condylomata lata: painless, wart-like lesion on palate, vulva, or scrotum (highly infectious).
  3. Late syphilis
     - Asymptomatic infection that follows untreated primary/secondary syphilis.
     - Early latent (<1 yr post-infection) or late latent/unknown duration (>1 yr post-infection).
     - Increased transmission risk with early latent; longer treatment duration required for late latent.
  4. Tertiary syphilis (1-30 yr post-infection)
     - Gummatous syphilis: nodular granulomas of skin, bone, liver, testes, brain.
     - Aortic aneurysm and aortic insufficiency.
     - Neurosyphilis: dementia, personality changes, Argyll-Robertson pupils, tabes dorsalis.
  5. Congenital syphilis
     - Causes spontaneous abortions, stillbirths, congenital malformations, developmental delay, deafness.
     - Most infected newborns are asymptomatic.
     - Clinical manifestation in early infancy include rhinitis (snuffles), lymphadenopathy, hepatosplenomegaly, pseudoparalysis (bone pain associated with osteitis) and rash (usually maculopapular and involving palms and soles).
     - Late onset manifestations (>2 yr of age) include saddle nose, saber shins, Glutton joints, Hutchinson's teeth, mulberry molars, rhagades, CN VIII deafness, interstitial keratitis, juvenile paresis.

Investigations
- Screening tests: CMIA, CLIA, EIA (treponemal), RPR, or VDRL (non-treponemal).
- Confirmatory tests: TPPA, FTA-ABS, MHA-TP, TPI, dark field microscopy with silver stain (rarely).
- LP for neurosyphilis if: seropositive and symptoms of neurosyphilis or treatment failure/other tertiary symptoms, or with HIV and late latent/unknown duration syphilis; consider in others.
- For congenital syphilis, LP is essential; long bone x-rays may also be helpful.

Treatment
- For 1st, 2nd, early latent: benzathine penicillin G 2.4 million units IM x 1.
- For 3rd, late latent: benzathine penicillin G 2.4 million units IM weekly x 3.
- If allergic to penicillin: doxycycline 100 mg PO bid x 14 d.
- Neurosyphilis: aqueous Penicillin G 18-24 million units/d IV x 14 d.
- For congenital syphilis, penicillin G IV x 10 d.
- See Family Medicine, FM42 for generalized STI workup.
Tuberculosis

Etiology, Epidemiology, and Natural History

- 1/3 of the world’s population is infected with TB
- contracted by aerosolized inhalation of Mycobacterium tuberculosis, a slow growing aerobe (doubling time = 18 h) that can evade innate host defenses, survive, and replicate in macrophages
- inhalation and deposition in the lung can lead to one of the following outcomes
  1. immediate clearance of the pathogen
  2. latent TB: asymptomatic infection contained by host immune defenses (represents 95% of infected people)
  3. primary TB: symptomatic, active disease (represents 5% of infected people)
  4. secondary TB: symptomatic reactivation of previously dormant TB (represents 5-10% of those with latent TB, most often within the first 1-2 yr of initial infection) at a pulmonary or extrapulmonary site

Risk Factors

- social and environmental factors
  - travel or birth in a country with high TB prevalence (e.g. Asia, Latin America, Sub-Saharan Africa, Eastern Europe)
  - Aboriginal (particularly Inuit), crowded living conditions, low SES/homeless, IVDU
  - personal or occupational contact
- host factors
  - immunocompromise/immunosuppressed (especially HIV, including extremes of age)
  - silicosis
  - chronic renal failure requiring dialysis
  - malignancy and chemotherapy
  - substance abuse (e.g. drug use, alcoholism, smoking)

Clinical Presentation

- primary infection usually asymptomatic, although progressive primary disease may occur, especially in children and immunosuppressed patients
- secondary infection/reactivation usually produces constitut oral symptoms (fatigue, anorexia, night sweats, weight loss) and site-dependent symptoms
  1. pulmonary TB
    - chronic productive cough ± hemoptysis
    - CXR consolidation or cavitation, lymphadenopathy
    - non-resolving pneumonia despite standard antimicrobial therapy
  2. miliary TB
    - widely disseminated spread especially to lungs, abdominal organs, marrow, CNS
    - CXR: multiple small 2-4 mm millet seed-like lesions throughout lung
  3. extrapulmonary TB
    - lymphadenitis, pleurisy, pericarditis, hepatitis, peritonitis, meningitis, osteomyelitis (vertebral = Pott’s disease), adrenal (causing Addison’s disease), renal, ovarian

Investigations

- screening for latent TB
  - PPD/Mantoux skin tests
    - both tests diagnose prior TB exposure; neither can diagnose or exclude active disease
IFN-γ release assay (IGRA)
- in patients previously infected with TB, T-cells produce increased amounts of IFN-γ when re-exposed to TB antigen
- detects antigen not present in the BCG vaccine or in most types of non-tuberculous-Mycobacteria (NTM), therefore fewer false positives
- Canadian and American guidelines treat IGRA as equivalent to the TB skin test and preferable in patients with a history of BCG vaccination or who may not return for a skin test reading

Diagnostic tests/investigations for active pulmonary TB
- three sputum specimens (either spontaneous or induced) should be collected for acid-fast bacilli smear and culture; the three specimens can be collected on the same day, a minimum of 1 hour apart
- BAL
- CXR
  - nodular or alveolar infiltrates with cavitation (middle/lower lobe if primary, apical if secondary)
  - pleural effusion (usually unilateral and exudative) may occur independently of other radiograph abnormalities
  - hilar/mediastinal adenopathy (especially in children)
  - tuberculoma (semi-calcified well-defined solitary coin lesion 0.5-4 cm that may be mistaken for lung CA)
  - miliary TB (see clinical features)
  - evidence of past disease: calcified hilar and mediastinal nodes, calcified pulmonary focus, pleural thickening with calcification, apical scarring

Prevention
- primary prevention
  - airborne isolation for active pulmonary disease
  - BCG vaccine
    - ~80% effective against pediatric miliary and meningeal TB
    - effectiveness in adults debated (anywhere from 0-80%)
    - recommended in high-incidence communities in Canada for infants in whom there is no evidence of HIV infection or immunodeficiency; widely used in other countries
- secondary prevention (defer in pregnancy unless mother is high risk)
  - likely INH-sensitive: isoniazid (INH) + pyridoxine (vit B6 to help prevent INH-associated neuropathy) x 9 mo
  - likely INH-resistant: rifampin x 4 mo

Treatment of Active Infection
- pulmonary TB: INH + rifampin + pyrazinamide + ethambutol + pyridoxine x 2 mo (initiation phase), then INH + rifampin + pyridoxine x 4 mo in fully susceptible TB (continuation phase), total 6 mo
- extrapulmonary TB: same regimen as pulmonary TB but increase to 12 mo in bone/joint, CNS, and miliary/disseminated TB + corticosteroids for meningitis, pericarditis
- empiric treatment of suspected MDR (multidrug resistant) or XDR (extensively drug-resistant) TB requires referral to a specialist
  - MDR = resistance to INH and rifampin ± others
  - XDR = resistance to INH + rifampin + fluoroquinolone + ≥1 of injectable, second-line agents
    - very difficult to treat, global public health threat, 5 documented cases in Canada from 1997-2008
  - suspect MDR TB if previous treatment, exposure to known MDR index case, or immigration from a high-risk area

HIV and AIDS

Epidemiology

Canadian Situation (Public Health Agency of Canada, 2013)
- estimated 71,300 Canadians living with HIV infection at the end of 2011, 25% unaware of HIV positive status
- 2,090 new infections were reported in 2013: MSM account for 49.3% of cases, IVDU 12.8%

Global Situation (WHO and UNAIDS Core Epidemiology Slides, July 2014)
- estimated 35 million people living with HIV/AIDS in 2013
- estimated 2.1 million newly infected in 2013
- estimated 1.5 million AIDS-related deaths in 2013

HIV-1 is the predominant type in North America and most of the world
HIV-2 is found mainly in West Africa
Both lead to AIDS but HIV-2 is generally less virulent
Etiology

- HIV is a retrovirus that causes progressive immune system dysfunction which predisposes patients to various opportunistic infections and malignancies.
- HIV virion includes an envelope (gp41 and gp120 glycoproteins), matrix (p17) and capsid (p24) enclosing 2 single-stranded copies of RNA plus enzymes in its core.
- Virion glycoproteins bind CD4 and CCR5/CXCR4 on CD4+ T lymphocytes (T-helper cells) to fuse and enter the cells.
- RNA converted to dsDNA by viral reverse transcriptase; dsDNA is integrated into host genome by viral integrase.
- Virus DNA transcribed and translated using host cell machinery, post-translational modifications include proteolytic activity of virally encoded protease enzymes.
- New virions bud out of host cell, incorporating host cell membrane; additional maturation steps are required before virions are considered infectious.
- Exact mechanisms of CD4 depletion incompletely characterized but likely include direct viral cytopathic effects, apoptosis, and increased cell turnover.

Modes of Transmission

Adapted with permission from Macmillan Publishers Ltd. Nat Rev Immunology 2008;8:447-457.

NOTE: these estimates are for “all comers” i.e. they estimate transmission risk for anyone with HIV infection and do not take into account treatment status of the HIV+ person (in contrast to results of PARTNER study).

Natural History

![Figure 9. HIV viral particle](image)

- **Acute Infection** Retroviral Syndrome
  - 40-90% experience an acute “flu-like” illness (may include fever, pharyngitis, lymphadenopathy, rash, arthralgias, myalgias, H/A, GI symptoms, oral ulcers, weight loss) 2-6 wk post-exposure lasting 10-15 d
  - hematologic disturbances (lymphopenia, thrombocytopenia)
  - 10-20% present with aseptic meningitis; HIV RNA and/or p24 may be detected in CSF
  - associated with a high level of plasma viremia and therefore high risk of transmission
Asymptomatic (Latent) Stage
- during latent phase, HIV infects and replicates in CD4+ T lymphocytes (lymph nodes)
- normal CD4 count in adults: 500-1,100 cells/mm³
- CD4 count drops 60-100 cells/mm³ per year
- by 10 yr post-infection, 50% have AIDS, 30% demonstrate milder symptoms, and <20% are asymptomatic if left untreated

Definition of AIDS
- HIV-positive AND one or more of the clinical illnesses that characterize AIDS, including: opportunistic infections (e.g. PJP (previously PCP), esophageal candidiasis, CMV, MAC, TB, toxoplasmosis), malignancy (Kaposi's sarcoma, invasive cervical cancer), wasting syndrome
- OR CD4 <200 (or <15%); this is largely historical since ART can reverse CD4 count decline

</tbody>
</table>

Laboratory Diagnosis
- anti-HIV antibodies detectable after a median of 3 wk, virtually all by 3 mo (therefore 3 mo window period)
- initial screening test (3rd generation antibody test): enzyme linked immunosorbent assay (ELISA) detects serum antibody to HIV; sensitivity >99.5%
- increasingly, combination p24 antigen/HIV antibody tests (4th generation) used for screening; improved sensitivity in early or acute infection and sensitivity/specificity approach 100% for chronic infection
- confirmatory test: if positive screen, Western blot confirmation by detection of antibodies to at least two different HIV protein bands (p24, gp41, gp120/160); specificity >99.99%
- rapid (point of care) antibody tests: higher false positives, therefore need to confirm positive results with traditional serology
- p24 antigen: detection by ELISA may be positive during “window period”

Management of the HIV Positive Patient
- verify positive HIV test
- complete baseline history and physical exam, then follow-up every 3-6 mo
- laboratory evaluation
  - routine CD4 count to measure status of the immune system
  - routine HIV-RNA levels (viral load)
  - also important indicator of effect of ART
  - baseline HIV resistance testing to guide ARV therapy
  - HLA-B*5701 genetic test to screen for abacavir hypersensitivity if considering abacavir in treatment regimen
  - CCR5 tropism testing if considering CCR5 antagonist in treatment regimen
  - baseline tuberculosis skin test (PPD): induration greater than 5 mm is positive
  - baseline serologies (hepatitis A, B, and C, syphilis, toxoplasmosis, CMV, VZV)
  - routine biochemistry and hematology, CXR, urinalysis
  - annual fasting lipid profile and fasting glucose (due to ART side effects)
- education
  - regular follow-up on CD4 counts and viral loads (q3-6mo) as well as strict adherence to ART improves prognosis
  - prevention of further transmission through safer sex and clean needles for IVDU
  - HIV superinfection (transmission of different HIV strains from another HIV+ person) does rarely occur so barrier protection during sex is still recommended
  - discuss importance of disclosing HIV status to partners including risk of criminal prosecution of non disclosure in jurisdictions where applicable
  - connect to relevant community groups and resources
• health care maintenance
  • assessment of psychosocial concerns and referral to psychiatry or social work if appropriate
  • vaccines influenza annually, 23-valent pneumococcal every 5 yr, HBV (if not immune), HAV (if seronegative)
  • annual screening (PAP smear, STIs)
  • management of comorbid conditions and provision of general primary care

SS = single strength; DS = double strength

### Anti-Retroviral Treatment

#### Overall Treatment Principles
- recommended that all HIV+ patients initiate combination ART to restore and preserve immune function, reduce morbidity, prolong survival and prevent transmission
- patients starting ART should be committed to treatment and understand the importance of adherence; poor compliance can lead to viral resistance; may defer treatment on the basis of clinical and psychosocial factors on case by case basis
- consider results of baseline resistance testing and complete ART history before (re-) initiating ART
- goal: keep viral load below limit of detection i.e. <40 copies/mL (undetectable); viral load should decrease 10-fold within 4-8 wk, be undetectable by 6 mo, and restore immunological function
- strong evidence against intermittent ART or ‘drug holidays’
- ART leads to 96% reduction in risk of transmitting HIV to sexual partners

#### ART Recommendations for Treatment of Naïve Patients
- 2 NRTIs + 1 INSTI/PI (boosted with ritonavir or cobicistat)

#### Treatment Failure
- defined primarily by viral load (persistently >200 copies/mL)
- ensure that viral load >40 is not just a transient v remia or ‘blip’; confirm medication adherence, assess drug interactions, perform resistance testing

### Anti-Retroviral pre-exposure prophylaxis (PrEP) for preventing HIV in high-risk individuals

**Cochrane DB Syst Rev 2012 Jul 11;7:CD007189.**

**Purpose:** To evaluate the efficacy of oral anti-retroviral prophylactic therapy in preventing HIV infection.

**Study:** Systematic review of 12 randomized controlled trials with 6 trials forming the core analysis.

**Population:** 9849 HIV-uninfected patients at high risk of contracting HIV including men who have sex with men, serodiscordant couples and others.

**Outcome:** New infection with HIV.

**Results:** Daily oral tenofovir disoproxil fumarate (TDF) plus emtricitabine (FTC) reduced the risk of HIV acquisition compared to placebo (RR 0.49; 95% CI 0.28-0.85). TDF alone also showed significant risk reduction in trials with fewer patients (RR 0.33; 95% CI 0.20-0.55). There was no significant increase in adverse events in any of the treatment groups. Sexual practices and adherence did not differ between treatment and placebo arms.

**Conclusions:** Pre-exposure prophylaxis with TDF with or without FTC effectively reduces the risk of HIV acquisition in high risk, HIV uninfected patients without causing significant adverse effects.

Prevention of HIV Infection
- education, including harm-reduction
  - safer sexual practices: condoms for vaginal and anal sex, barriers for oral sex
  - harm reduction for IVDU: avoid sharing needles
- prevention of vertical HIV infection: treatment with ART should be initiated prior to pregnancy or as early as possible during pregnancy. The risk of vertical HIV transmission can be reduced to < 1% if maternal ART is started in a timely manner and the maternal viral load is undetectable prior to delivery.
- universal blood and body precautions for health care workers
  - post-exposure prophylaxis (PEP) after occupational (e.g. needle-stick injury) and non-occupational (e.g. consensual sex, sexual assault) exposure to HIV: 2- or 3-drug regimen initiated immediately (<72 h) after exposure and continuing for 4 wk
- recent data has demonstrated efficacy of pre-exposure prophylaxis (oral PrEP or topical microbicides) in preventing HIV
- ART associated with 96% reduction in risk of transmitting HIV to sexual partners
- screening of blood and organ donation

Figure 11. Mechanism of HIV replications
Types of Testing

1. Nomina /Name-Based HIV Testing
   - person ordering the test knows the identity of the person being tested for HIV
   - HIV test is ordered using the name of the person being tested
   - person ordering the test is legally obligated to notify Public Health officials if test results are positive for HIV
   - test result is recorded in the health care record of the person being tested

2. Non-Nominal/Non-Identifying HIV Testing
   - similar to nominal/name-based testing on all points except:
   - HIV test is ordered using a code or the initials of the person being tested

3. Anonymous Testing
   - available at specialized clinics
   - person ordering the HIV test does not know the identity of the person being tested
   - HIV test is carried out using a unique non-identifying code that only the person being tested for HIV knows
   - test results are not recorded on the health care record of the person being tested
   - patient identification and notification of Public Health required to gain access to ART

HIV Pre- and Post-Test Counselling

- a diagnosis of HIV can be overwhelming and is often associated with stigma and discrimination
- consider pre- and post-test counselling, regardless of the results
- goals include: assessing risk, making informed decision to be tested, education to protect themselves and others from virus exposure, where to go for more information and support
- HIV+ patients should be connected with local support services

Fungal Infections

Skin and Subcutaneous Infections

Superficial Fungal Infections

- see Dermatology, D25

Dermatophytes

- see Dermatology, D26

Subcutaneous Fungal Infection

Etiology
- subcutaneous inoculation by fungi that naturally reside in the soil, including *Sporothrix schenckii*, which usually occurs in gardeners injured by a rose thorn or splinter

Clinical Presentation
- causes subcutaneous nodules at the point of entry, may develop into an ulcer
- fungi may migrate up lymphatic vessels creating nodules along the way – “nodular lymphangitis”

Treatment
- oral azole (e.g. itraconazole)
- IV amphotericin B for severe or disseminated infection

Endemic Mycoses

Etiology
- fungal infection that occurs through the inhalation of spores (from soil, bird droppings, vegetation) or inoculation injury
- thermally dimorphic organisms: mould in cold temperature (e.g. soil) and yeast at higher temperature (e.g. tissue)
- in North America, the three major endemic mycoses are: histoplasmosis, blastomycosis, and coccidioidomycosis
Clinical Presentation
- may be asymptomatic
- all can cause pneumonia and may disseminate hematogenously
- may reactivate or disseminate during immunocompromised states

Treatment
- common to all endemic mycoses
  - oral azole (e.g. itraconazole for mild-moderate local infection)
  - IV amphotericin B for systemic infection

</tbody>
</table>

Opportunistic Fungi

Pneumocystis jiroveci (formerly P. carinii)
Pneumonia: PJP or PCP

Etiology
- respiratory exposure to a unicellular fungi (previously classified as a protozoa)
- rarely transmitted from person to person
- without prophylaxis, HIV patients with a CD4 count <200 cells/mm³ have an 80% lifetime risk of PJP

Clinical Presentation
- symptoms of pneumonia: fever, nonproductive cough, progressive dyspnea
- classic CXR
- most clinical disease is due to reactivation of latent infection or reinfection by a different genotype in immunocompromised patients (steroid use, HIV)

Investigations
- demonstration of organism in induced sputum, bronchoalveolar lavage, or endotracheal aspirate (if intubated)

Treatment and Prevention
- oxygen to keep SaO₂ >90%
- antimicrobial options
  - TMP/SMX (PO or IV)
  - dapsone and TMP
  - clindamycin and primaquine
  - pentamidine (IV)
  - atovaquone
- corticosteroids used as adjuvant therapy in those with severe hypoxia (pO₂ <70 mmHg or A-a gradient O₂ >35 mmHg)
- prophylactic TMP/SMX for those at high risk of infection (HIV patients when CD4 <200 cells/mm³ or non HIV immunocompromised patients under specific conditions)
**Cryptococcus spp.**

**Etiology**
- inhalation of airborne encapsulated yeast from soil contaminated with pigeon droppings (C. neoformans) or certain tree species such as Eucalyptus or Douglas fir (C. gattii)
- C. neoformans tends to affect immunocompromised hosts vs. C. gattii which tends to affect immunocompetent hosts

**Clinical Presentation**
- asymptomatic
- pulmonary
  - usually asymptomatic or self-limited pneumonitis
  - only 2% of HIV+ patients present with pulmonary symptoms including productive cough, chest tightness, and fever
- disseminated
  - frequently disseminates in HIV+ population
  - CNS: meningitis (leading cause of meningitis in patients with HIV)
  - skin: umbilicated papules that resemble large lesions of Molluscum contagiosum
  - other: bone, lymph nodes, bone marrow, soft tissues, eyes

**Investigations**
- serum cryptococcal antigen
- CSF for meningitis: India-ink stain, cryptococcal antigen test, culture to confirm

**Treatment**
- in patients with HIV who have cryptococcal meningitis or severe pulmonary disease:
  - amphotericin B (+ flucytosine) is used in the first 2 wk for induction therapy; limited duration due to side effects
  - switch to fluconazole for at least 8 wk as consolidation therapy, then continue at lower dose for prolonged maintenance

---

**Candida albicans**

**Etiology**
- overgrowth of C. albicans (normally found as part of the microbiome of the skin, mouth, vagina and GI tract)
- risk factors for overgrowth:
  - immunocompromised state (DM, corticosteroids)
  - ICU patients (broad-spectrum antibiotic use, central venous catheters, TPN)
  - obesity → maceration and moisture in intertriginous areas, pannus, under breasts

**Clinical Presentation**
- mucocutaneous
  - oral thrush, esophagitis (chest pain, odynophagia), vulvovaginitis (see Gynecology, GY26), balanitis, cutaneous (diaper rash, skin folds, folliculitis), chronic mucocutaneous
  - small satellite lesions beyond the margin of the rash
- invasive
  - candidemia, endophthalmitis, endocarditis, UTI (upper tract), hepatosplenic disease

**Treatment**
- thrush: nystatin suspension or pastilles for mild disease, fluconazole for severe disease
- vulvovaginal candidiasis: topical agents (imidazole or nystatin), oral fluconazole for recurrent disease
- cutaneous infection: topical imidazole
- opportunistic infections in HIV, other systemic infections: fluconazole or echinocandin
- chronic mucocutaneous: azoles
Aspergillus spp.

Etiology
- infection with Aspergillus fungi (A. fumi, A. flavus) which is found ubiquitously in the air and the environment
  - Aspergillus produces a toxin called aflatoxin that contaminates nuts, grains, and rice

Clinical Presentation
- allergic bronchopulmonary aspergillosis (ABPA)
  - IgE-mediated asthma-type reaction with dyspnea, high fever, and transient pulmonary infiltrates
  - occurs more frequently in patients with asthma and allergies
- aspergilloma (fungus ball)
  - ball of hyphae in a preexisting lung cavity
  - symptoms range from asymptomatic to massive hemoptysis
  - CXR: round opacity surrounded by a thin lucent rim of air, often in upper lobes ("air crescent" sign)
- invasive aspergillosis
  - associated with prolonged and persistent neutropenia or transplantation
  - pneumonia – most common
  - may disseminate to other organs: brain, skin
  - severe symptoms with fever, cough, dyspnea, cavitation; fatal if not treated early and aggressively
  - CXR: local or diffuse infiltrates ± pulmonary infarction, pulmonary nodules with surrounding ground glass ("halo" sign)
- mycotoxicosis
  - aflatoxin produced by A. flavus (nuts, grains, rice)
  - results in liver hemorrhage, necrosis, and hepatocellular carcinoma formation

Treatment Options
- for invasive aspergillosis: voriconazole or amphotericin B
- surgical resection for aspergilloma
- corticosteroids ± itraconazole for Allergic Bronchopulmonary Aspergillosis

Protozoa – Intestinal/Genitourinary Infections

Entamoeba histolytica (Amoebiasis)

Etiology
- infection with E. histolytica occurs when the cysts are transmitted via the oral-fecal route in areas of poor sanitation that have been contaminated by other infected humans
- seen in migrants, travellers, institutionalized individuals, Aboriginal Canadians, MSM

Clinical Presentation
1. asymptomatic carriers
2. amoebic dysentery
   - abdominal pain, cramping, colitis, dysentery, low grade fever with bloody diarrhea secondary to local tissue destruction and ulceration of large intestine
3. amoebic abscesses (liver abscesses, see General Surgery, GS43)
   - most common in liver (hematologic spread); presents with RUQ pain, weight loss, fever, hepatomegaly
   - can also occur in lungs and brain

Investigations
- serology, fecal/serum antigen testing, stool exam (for cysts and trophozoites), colon biopsy
- E. histolytica indistinguishable microscopically from the non-pathogen E. dispar (distinguish by specific stool antigen detection)

Treatment and Prevention
- metronidazole
- for invasive disease or cyst elimination: follow with iodoquinol or paromomycin
- aspiration of hepatic abscess if risk of cyst rupture, poor response to medical therapy, or diagnostic uncertainty
- asymptomatic cyst shedding: iodoquinol or paromomycin alone
- good personal hygiene, purification of water supply by boiling, filtration (not chlorination)
Giardia lamblia

**Etiology**
- infect on with *G. lamblia* occurs via the fecal-oral route with the ingestion of cysts from water/food contaminated by infected humans and other mammals (especially in the Rockies)
- risk factors: travel, camping, institutions, day care centres, MSM

**Clinical Presentation**
- giardiasis ("beaver fever")
  - symptoms vary from asymptomatic to self-limited mild watery diarrhea to malabsorption syndrome (chronic giardiasis where the parasite coats the small intestine and thus prevents fat absorption)
  - nausea, malaise, abdominal cramps, bloating, flatulence, fatigue, weight loss, steatorrhea
  - no hematochezia (no invasion into intestinal wall), no mucous in stool

**Investigations**
- multiple stool samples (daily x 3 d) for microscopy, stool antigen used occasionally
- occasionally small bowel aspirate or biopsy

**Treatment and Prevention**
- metronidazole; nitazoxanide if symptomatic
- good personal hygiene and sanitation, water purification (iodine better than chlorination), outbreak investigation

Trichomonas vaginalis

**Etiology**
- infection with *T. vaginalis* occurs via sexual contact

**Clinical Presentation**
- often asymptomatic (10-50%), especially males (occasionally urethritis, prostatitis)
- *Trichomonas vaginalis* (see Gynecology, GY27)
  - vaginal discharge (profuse, malodourous, yellow-green or grey, frothy), pruritus, dysuria, dyspareunia

**Investigations**
- wet mount (motile parasites), antigen detection, culture
- urine PCR to detect in males

**Treatment**
- metronidazole for patient and partner(s)

Cryptosporidium spp.

**Etiology**
- infection with *Cryptosporidium* spp. via the fecal-oral route occurs with the ingestion of cysts from water contaminated by infected humans and other animals (including cows)
- risk factors: summer and fall, young children (day care), MSM, contact with farm animals, immunodeficiency

**Clinical Presentation**
- range from self-limited watery diarrhea (immunocompetent) to chronic, severe, non-bloody diarrhea with N/V, abdominal pain, and anorexia resulting in weight loss and death (immunocompromised)

**Investigations**
- modified acid-fast stain of stool specimen, microscopic identification of oocysts in stool or tissue, stool antigen detection by direct fluorescent antibody

**Treatment and Prevention**
- supportive care
- in HIV+ patients, (re)initiate ART and try to increase their CD4 count to >100; if fails, try nitazoxanide
- good personal hygiene, water filtration
**Blood and Tissue Infections**

**Plasmodium spp. (Malaria)**

**Etiology**
- Transmission of *Plasmodium* spp. (P. falciparum, P. vivax, P. ovale, P. malariae, P. knowlesi) primarily occurs during the blood meal of a night-biting female *Anopheles* mosquito
- Sporozoites injected during the blood meal then infect human liver cells, where they multiply and are released as merozoites; merozoites infect RBCs and cause disease
- Infection with malaria parasites can also occur via vertical transmission (rare) or blood transfusion
- Occurs in tropical/subtropical regions (sub-Saharan Africa, Oceania, South Asia, Central America, Southeast Asia, South America)

**Clinical Presentation**
- Flu-like prodrome
- Paroxysms of high spiking fever and shaking chills (due to synchronous systemic lysis of RBCs) (lasts several hours)
  - P. vivax and P. ovale: chills and fever x48 h but can be variable
  - P. malariae: chills and fever x72 h but can be variable
  - P. falciparum: less predictable fever interval, can be highly variable
- Abdominal pain, diarrhea, myalgia, H/A, and cough
- Hepatosplenomegaly and thrombocytopenia without leukocytosis
- >90% of patients infected with *P. falciparum* are ill within 30 d
- Relapsing malarial attacks may occur after many months due to the reactivation (entering the erythrocytic cycle) of dormant liver hypnozoites of either *P. ovale* or *P. vivax*
- Complications:
  - P. falciparum (most common and most lethal): CNS involvement (cerebral malaria = seizures and coma), severe anemia, acute kidney injury, ARDS, primarily responsible for fatal disease
  - P. knowlesi, and rarely *P. vivax*, can be fatal

**Investigations**
- Microscopy: blood smear q12-24h (x3) to rule out infection
- Thick smear (Giemsa stain) for presence of organisms
- Thin smear (Giemsa stain) for species identification and quantification of parasites
- Rapid antigen detection tests

**Treatment and Prevention**
- *P. vivax, P. ovale*: chloroquine (and primaquine to eradicate liver forms)
- *P. vivax*, chloroquine resistant: atovaquone/proguanil + primaquine or quinine and doxycycline + primaquine
- *P. malariae, P. knowlesi*: chloroquine
- *P. falciparum*: most areas of the world show chloroquine resistance – check local resistance patterns
  - Artemisinin combination therapy (e.g. artesunate + doxycycline or clindamycin or atovaquone/proguanil)
  - Atovaquone/proguanil combination (Malarone®)
  - Quinine + doxycycline or clindamycin
- Mefloquine and artemisinin resistance increasing in southeast Asia (check local resistance)
- Prevention with antimalarial prophylaxis, covering exposed skin, bed nets, insect repellent

**Trypanosoma cruzi**

**Etiology**
- Found in Mexico, South America, and Central America
- Transmission by Reduviid insect vector (“Kissing Bug”), which defecates on skin and tryptomastigotes in the stoe are rubbed into bite site by host
- Also transmitted via placental transfer, organ donation, blood transfusion, and ingestion of contaminated food containing Reduviid insects (especially cane juice)

**Clinical Presentation**
- American trypanosomiasis (Chagas disease)
  - Acute: usually asymptomatic, local swelling at site of inoculation (“Romana’s sign”; usually around one eye) with variable fever, lymphadenopathy, cardiomegaly, and hepatosplenomegaly
  - Chronic indeterminate phase: asymptomatic but increasing levels of antibody in blood, most infected persons (60-70%) remain in this phase, and do not go on to manifest a determinate form of Chagas disease
  - Chronic determinate: leads to chronic dilated cardiomyopathy, esophagomegaly, and megacolon 10-25 yr after acute infection in 30-40% of infected individuals

**Figure 13. Life cycle of Plasmodium spp.**

**Drugs for Preventing Malaria in Travellers**

**Cochrane DB Syst Rev 2009;CD006491**

**Study:** Cochrane Systematic Review: 8 RCTs.

**Population:** 4,240 non-immune adults and children traveling to regions with *P. falciparum* resistance to chloroquine.

**Intervention:** Atovaquone-proguanil, doxycycline, mefloquine, chloroquine-proguanil, or primaquine used for malaria prophylaxis.

**Outcome:** Efficacy, safety, and tolerability.

**Results:** Atovaquone-proguanil and doxycycline had similar adverse events. Atovaquone-proguanil had fewer overall (RR 0.72), GI (RR 0.54), and neuropsychiatric events (RR 0.49) than mefloquine. Doxycycline also had fewer neuropsychiatric events than mefloquine (RR 0.84).

**Conclusion:** Atovaquone-proguanil or doxycycline as prophylaxis against malaria is best tolerated in terms of adverse effects and mefloquine is associated with adverse neuropsychiatric outcomes.
Investigations
• wet prep and Giemsa stain of thick and thin blood smear, serology, PCR

Treatment and Prevention
• acute: nifurtimox or benznidazole
• indeterminate: increasing trend to treat as acute infection for children and adults under age 50 years
• chronic indeterminate: symptomatic therapy, surgery as necessary including heart transplant, esophagectomy, and colectomy; there may be a benefit to antiparasitic treatment
• insect control, bed nets

**Toxoplasma gondii**

Etiology
• infection with *T. gondii* occurs through exposure to cat feces (oocysts), ingestion of undercooked meat (tissue cysts), vertical transmission, organ transplantation, gardening without gloves (cat oocyst exposure), whole blood transfusions

Clinical Presentation
• congenital
  ■ result of acute primary infection of mother during pregnancy (see Obstetrics, OB29, TORCH infection)
  ■ stillbirth (rare), chorioretinitis, blindness, seizures, severe developmental delay, microcephaly
  ■ initially asymptomatic infant may develop reactivation of chorioretinitis as adolescent or adult
  ■ blurred vision, scotoma, ocular pain, photophobia, epiphora, hearing loss, developmental delay
  ■ usually asymptomatic or mononucleosis-like syndrome in immunocompetent patient
  ■ infection remains latent for life unless reactivation due to immunosuppression
• immunocompromised (most commonly AIDS with CD4 <200)
  ■ encephalitis with focal CNS lesions seen as single or multiple ring-enhancing masses on CT (H/A and focal neurological signs)
  ■ lymph node, liver, and spleen enlargement and pneumonitis
  ■ chorioretinitis

Investigations
• serology, CSF Wright-Giemsa stain, antigen or DNA detection (PCR); pathology provides definitive diagnosis
• immunocompromised patients: consider CT scan (ring enhancing lesion in cortex or deep nuclei) and ophthalmologic examination
• negative serology in many AIDS patients (false negative due to decreased lymphocyte population)

Treatment and Prevention
• no treatment if: immunocompetent, not pregnant, no severe organ damage
• pregnancy: spiramycin to prevent transplacental transmission or pyrimethamine + sulfadiazine (add folinic acid), avoid undercooked meat and refrain from emptying cat litter boxes
• HIV: pyrimethamine + sulfadiazine (see Prophylaxis, ID30)
• eye disease, meningitis: corticosteroids
• proper hand hygiene, cook meat thoroughly to proper temperature

TREMATODES

| Clonorchis sinensis | Japan, Taiwan, China, SE Asia | Raw fish | Exists in bile ducts, causes inflammation and sometimes cholangiocarcinoma | Praziquantel |
| Schistosoma spp. | Africa, SE Asia, focal in Western Hemisphere | Fresh water exposure | Chronic sequelae secondary to long-term infection (e.g. chronic liver disease, SCC of the bladder) | Praziquantel |

Schistosoma spp.

Etiology
- Infection with Schistosoma spp. (S. mansoni, S. hematobium, S. japonicum) occurs following penetration of unbroken skin by their larvae (cercariae) which are found in infested fresh water
- Adult worms live in terminal venules of bladder/bowel passing eggs into urine/stool
- Eggs must reach fresh water to hatch where they infect an intermediate host (snails) which then release cercariae into the water
- Schistosomes cannot multiply in or pass between humans
- More common in individuals from sub-Saharan Africa, South America, Asia, Caribbean, Eastern Mediterranean/North Africa

Clinical Presentation
- Most asymptomatic; symptoms seen in travellers (nonimmune)
- Swimmer’s itch: pruritic skin rash at site of penetration (cercarial dermatitis)
- Acute schistosomiasis (Katayama fever): hypersensitivity to migrating parasites (4-8 wk after infection)
  - Fever, hives, H/A, weight loss, cough, abdominal pain, chronic diarrhea, high-grade eosinophilia
- Chronic schistosomiasis (can persist for years):
  - S. mansoni, S. japonicum
    - Worms in mesenteric vein, eggs in portal tracts of liver and bowel
    - Heavy infections: intestinal polyps, portal and pulmonary HTN, splenomegaly (2+ to portal HTN), hepatomegaly
  - S. hematobium
    - Worms in vesical plexus, eggs in distal ureter and bladder induce granulomas and fibrosis
    - Hematuria and obstructive uropathy; associated with squamous cell bladder cancer
    - Neurologic complications: spinal cord neuroschistosomiasis (transverse myelitis), cerebral or cerebellar neuroschistosomiasis (increased ICP, focal CNS signs, seizures)
    - Pulmonary complications: granulomatous pulmonary endarteritis, pulmonary HTN, cor pulmonale; especially in patients with hepatosplenic involvement

Investigations
- Serology (high sensitivity and specificity), CBC (eosinophilia, anemia, thrombocytopenia)
- S. mansoni, S. japonicum: eggs in stool, liver U/S shows fibrosis, rectal biopsy
- S. hematobium: bladder biopsy, eggs in urine and occasionally stool, kidney and bladder U/S

Figure 17. Life cycle of Schistosoma
Treatment and Prevention
- praziquantel
- add glucocorticoid if acute schistosomiasis or neurologic complications develop
- proper disposal of human fecal waste, molluscicide (pesticide against molluscs), avoidance of infested fresh water while traveling

Ectoparasites
- scabies, lice
- see Dermatology, D26

Travel Medicine

General Travel Precautions
- vector-borne: long sleeves, long pants, hats, repellents (containing permethrin) applied to clothes, belongings, and bed nets, and skin repellents (such as DEET) applied to exposed skin
- food/water: avoid eating raw meats/seafood, uncooked vegetables, and milk/dairy products; drink only bottled beverages, chlorinated water, boiled water
- recreation: caution when swimming in schistosomiasis-endemic regions (Lake Malawi), fresh water rafting/kayaking, beaches that may contain human/animal waste products, near storm drains, after heavy rainfalls
- prophylaxis: malaria (chloroquine, mefloquine, atovaquone + proguanil, doxycycline), traveller’s diarrhea (bismuth salicylate), standard vaccines up to date (hepatitis B, MMR, tetanus/diphtheria, varicella, pertussis, polio, influenza)
- travel vaccines: hepatitis A/B, Japanese encephalitis, typhoid fever, yellow fever, rabies, ETEC, cholera
- sexually transmitted and blood-borne infections: safe sex practices, avoidance of percutaneous injury
- vector-borne: long sleeves, long pants, hats, repellents (containing permethrin) applied to clothes, belongings, and skin repellents (such as DEET) applied to exposed skin
- food/water: avoid eating raw meats/seafood, uncooked vegetables, and milk/dairy products; drink only bottled beverages, chlorinated water, boiled water
- recreation: caution when swimming in schistosomiasis-endemic regions (Lake Malawi), fresh water rafting/kayaking, beaches that may contain human/animal waste products, near storm drains, after heavy rainfalls
- prophylaxis: malaria (chloroquine, mefloquine, atovaquone + proguanil, doxycycline), traveller’s diarrhea (bismuth salicylate), standard vaccines up to date (hepatitis B, MMR, tetanus/diphtheria, varicella, pertussis, polio, influenza)
- travel vaccines: hepatitis A/B, Japanese encephalitis, typhoid fever, yellow fever, rabies, ETEC, cholera

Infectious Diseases to Consider
- vector borne: malaria, dengue fever, Chikungunya, yellow fever, spotted fever rickettsioses, West Nile virus, typhoid fever
- sexually transmitted: HIV, HBV, acute HSV, syphilis usual STIs
- zoonotic: rabies, hantavirus, tularemia, Q fever, leptospirosis, brucellosis
- airborne: TB
- food/water: HAV, HEV, brucellosis, typhoid, paratyphoid, amoebiasis, dysentery, traveller’s diarrhea, cholera, Campylobacter spp.
- soil/water: schistosomiasis, strongyloidiasis, leptospirosis, cutaneous larva migrans, histoplasmosis, paracoccidioidomycosis

Fever in the Returned Traveller

Etiology
- commonly identified causes of fever in returning traveller
  - parasitic: malaria (20-30%), schistosomiasis, hookworms
  - viral: non specific mononucleosis-like syndrome (4-25%), dengue (5%), viral hepatitis (3%)
  - bacterial: from Salmonella (2-7%), rickettsioses (3%)
  - diverse group of causative pathogens: traveller’s diarrhea (10-20%), RTI (10-15%), UTI/STI (2-3%)
  - febrile illness in travellers can be caused by routine infections that are common in non-travellers (e.g. URTI, UTI)
  - less commonly, fever can be due to non-infectious causes (e.g. DVT, PE)

History
- pre-travel preparation
- travel itinerary: when, where, why, what, who, how?
  - dates of travel (determine incubation period)
  - season of travel: wet or dry
  - destination: country, region (urban or rural), environment (jungle, desert, etc.)
  - purpose of trip
- persons visiting friends and family more likely to be exposed to local population and pathogens
  - style of travel: lodgings, camping, adventure travelling
  - local population: sick contacts
  - transportation: use of animals

Important Exposures

Insect Bites
- Mosquito: Plasmodium spp. (Malaria), Anopheles spp., Aedes aegypti
- Tick: Borrelia burgdorferi (Lyme Disease), Ixodes scapularis (Rocky Mountain Spotted Fever)
- Fly: Tsetse fly (sleeping sickness)
- Flea: Yersinia (Plague), Bartonella bacilliformis

Mammal Bites
- Dog/Cat: Rabies, Pasteurella, anaerobes, Streptococcus, S. aureus
- Human: Streptococcus, S. aureus, oral anaerobes, Eikenella

Oral Exposures
- Unpasteurized Milk: Brucella spp., non-tuberculous Mycobacteria, Salmonella, E. coli, Listeria
- Undercooked Meat/Fish: Enteric bacteria, helminths, protozoa
- Water: Hepatitis A/E, Norovirus, cholera, Salmonella, Shigella, Giardia, poliovirus, Cryptosporidium, Cyclospora

Environmental Exposures
- Fresh Water: Lactoporella spp., schistosomiasis, Acanthamoeba, Naegleria fowleri
- Soil: Helminths, Taenaria sp., Strongyloides, Necator americanus, Ascaris lumbricoides, Capillaria hepatica

Adapted with permission from Lancet 2003;361:1459-69
• exposure history
  ■ street foods, untreated water: increased risk of traveller’s diarrhea, enteric fever
  ■ uncooked meat/unpasteurized dairy: increased risk of parasitic infection
  ■ body fluids (sexual contacts, tattoos, piercings, IVDU, other injections)
  ■ increased risk of HBV, HCV, HIV, GC, C. trachomatis, syphilis
  ■ animal/insect bites: increased risk of malaria, dengue, rickettsioses, rabies

• fever pattern

• incubation period: use the earliest and latest possible dates of exposure to narrow the differential diagnosis and exclude serious infections
  ■ <21 d: consider malaria, typhoid fever, dengue fever, chikungunya, rickettsioses; exclude HBV, TB
  ■ >21 d: consider malaria, TB, typhoid fever; exclude dengue fever, chikungunya, traveller’s diarrhea, rickettsioses

• body systems affected: GI, respiratory, CNS, skin

Investigations

• all travellers with fever should undergo the following tests
  ■ blood work: CBC and differential, liver enzymes, electrolytes, creatinine, thick and thin blood smears x3 (for malaria), blood C&S
  ■ urine: urinalysis, urine C&S if dysuria or other localizing signs

• special tests based on symptoms, exposure history, and geography
  ■ stool: C&S, O&P
  ■ CXR
  ■ dengue serology for IgM

Table 28. Fever in the Returned Traveller

</tbody>
</table>

Etiology of Classic FUO
- infectious causes (~30%)
  - TB: extra pulmonary (most common), miliary, pulmonary (if pre-existing disease)
  - abscess: subphrenic, liver, splenic, pancreatic, perinephric, diverticular, pelvis, psoas
  - osteomyelitis
  - bacterial endocarditis (culture negative)
  - uncommon: viral (CMV, EBV), bacterial (brucellosis, bartonellosis), fungal (histoplasmosis, cryptococcosis), parasitic (toxoplasmosis, leishmaniasis, amebiasis, malaria)
- neoplastic causes (~20%)
  - most commonly lymphomas (especially non-Hodgkin's) and leukemias, also multiple myeloma, myelodysplastic syndrome
  - solid tumours: RCC (most common), also breast, liver (hepatoma), colon, pancreas, or liver metastases
- collagen vascular diseases (~30%)
  - SLE, RA, rheumatic fever, vasculitis (temporal arteritis, PAN), JRA, Still's disease
- miscellaneous (~20%)
  - drugs, factitious fever
  - sarcoidosis, granulomatous hepatitis, IBD
  - hereditary periodic fever syndromes (such as familial Mediterranean fever)
  - venous thromboembolic disease: PE, DVT
  - endocrine: thyroiditis, thyroid storm, adrenal insufficiency, pheochromocytoma
- unknown in 30-50% despite detailed workup

Approach to Classic FUO
- careful history: travel, environmental/occupational exposures, infectious contacts, medication history, immunizations, TB history, sexual history, past medical history, comprehensive review of systems (including symptoms that resolved before interview)
- thorough physical exam: fever pattern, rashes (skin, mucous membranes), murmurs, arthritis, lymphadenopathy, organomegaly
- initial investigations as appropriate
  - blood work: CBC and differential, electrolytes, BUN, Cr, calcium profile, LFTs, ESR, CRP, muscle enzymes, RF, ANA, serum protein electrophoresis (SPEP), blood smear
  - cultures: blood (x2 sets), urine, sputum, stool C&S, O&P, other fluids as appropriate
  - serology: HIV monospot, CMV IgM
  - imaging: CXR, abdominal imaging
- if there are diagnostic clues from any of the above steps, proceed with directed exam, biopsies or invasive testing as required, followed by directed treatment once a diagnosis is established
- if no diagnosis with the above, consider empiric therapy vs. watchful waiting
  - without intervention: patients that remain undiagnosed despite extensive workup have good prognosis
- immunocompromised hosts have increased susceptibility to infections from pathogens that are typically low virulence, commensal, or latent
- type of immunodeficiency predicts probable spectrum of agents

Causes of Nosocomial FUO
B, C, D, E
- Bacterial and fungal infections of respiratory tract and surgical sites
- Catheters (intravascular and urinary)
- Drugs (intravascular and urinary)
- Emboli

Drugs that may Cause Fever
- Anti-microbials (sulfonamides, penicillins, nitrofurantoin, antimicrobials)
- Anti-hypertensives (hydralazine, methyldopa)
- Anti-epileptics (barbiturate, phenytoin)
- Anti-arythmics (quinine, procainamide)
- Anti-inflammatory (NSAIDs)
- Anti-thrombotics (ASA)
- Anti-histamines
- Anti-thyroid
Infections in the Immunocompromised Host

Factors that Compromise the Immune System

- general: age (very young or elderly), malnutrition
- immune disease: HIV/AIDS, malignancies, asplenia (functional or anatomic), hypogammaglobulinemia, neutropenia
- DM
- iatrogenic: corticosteroids, chemotherapy, radiation treatment, anti-TNF therapy, other immunosuppressive drugs (e.g. in transplant patients)

<tr>
<td>Humoral Immunity</td>
<td>CLL, lymphosarcoma, multiple myeloma, nephrotic syndrome, protein-losing enteropathy, burns, sickle cell anemia, asplenia, splenectomy, selective Ig deficiencies, Wiskott-Aldrich syndrome</td>
<td>Encapsulated organisms (S. pneumoniae, H. influenzae, N. meningitidis, Salmonella typhi, GBS)</td>
</tr>
<tr>
<td>Neutrophil Function</td>
<td>Myelodysplasia, paroxysmal nocturnal hemoglobinuria, radiation, cytotoxic drug therapy, C3 or C5 deficiencies, chronic granulomatous disease</td>
<td>Catalase-producing organisms (Staphylococcus, Serratia, Nocardia, Aspergillus)</td>
</tr>
</tbody>
</table>

Febrile Neutropenia

Definition
- fever (≥38.3°C/101°F or ≥38.0°C/100.4°F for ≥1 h) and one of
  - ANC <0.5 OR
  - ANC <1.0 but trending down to 0.5

Pathophysiology
- decreased neutrophil production
  - marrow: infection, aplastic/myelophthisic anemia, leukemia, lymphoma, myelodysplastic syndromes
  - iatrogenic: cancer chemotherapy, radiation, drugs
  - deficiencies: vitamin B12, folate
- increased peripheral neutrophil destruction
  - autoimmune: Felty’s syndrome, SLE, antineutrophil antibodies
  - splenic sequestration

Epidemiology/Etiology
- most common life-threatening complication of cancer therapy
- causative organism identified only 1/3 of the time
- GN (especially Pseudomonas) historically most common
- GP more common now
- fungal superinfection if neutropenia prolonged or if concurrent antibiotic use (especially Candida, Aspergillus)

Investigations
- examine for potential sites of infection: mucositis and line infections are most common
- do NOT perform DRE; examine perianal region
- blood C&S (≥2 sets), urine C&S, culture all indwelling catheter ports, ± sputum C&S and nasopharyngeal swab for respiratory viruses
- CBC and differential, Cr, BUN, electrolytes, AST/ALT, total bilirubin

Treatment
- most hospitals have their own specific protocol; one example see Figure 18
Infections in the Immunocompromised Host

Figure 18. Example of treatment protocol for febrile neutropenia

Infections in Solid Organ Transplant Recipients

- Infection is a leading cause of early morbidity/mortality in transplant recipients
- Infection depends on degree of immunosuppression
- Common infections <1 mo post-transplant
  - Bacterial infection of wound/lines/lungs, herpetic stomatitis
- Common infections >1 mo post-transplant
  - Viral (especially CMV, EBV, VZV)
  - Fungal (especially Aspergillus, Cryptococcus, P. jiroveci)
  - Protozoan (especially Toxoplasma)
  - Unusual bacterial/mycobacterial infections (especially TB, Nocardia, Listeria)

Prophylactic Vaccinations Given Before Transplant

- To all transplant patients: DTaP, pneumococcal, influenza, hepatitis A and B vaccines
- If low titre or poor documentation: MMR, polio, varicella vaccination (with booster 4-8 wk later)

Immune Reconstitution Syndrome

Definition

- A harmful inflammatory response directed against a previously acquired infection following a recovery of the immune system

Etiology

- Paradoxical worsening of a successfully or partially treated opportunistic infection
- New onset response to a previously unidentified opportunistic infection
- The majority of cases are in HIV/AIDS or immunosuppressed patients starting anti-retroviral therapy or discontinuing immunosuppressive therapy; sudden recovery from an immunosuppressive state towards a pro-inflammatory state directed towards subclinical infection results in fever and inflammation
- Can occur in response to multiple infections
  - Mycobacteria (tuberculosis, avium complex)
  - Cryptococcus
  - Pneumocystis
  - Toxoplasma
  - HBV and HCV
  - Herpes viruses (VZV reactivation, HSV, CMV)
  - JC virus (progressive multifocal leukoencephalopathy)
  - Molluscum contagiosum
- Clinical features are dependent on the type and location of the pre-existing infection
- Thought to be worse with a quick increase in CD4 count and with lower pre-treatment CD4 count
- Non HIV conditions with documented IRS: solid organ transplant recipients, post-partum women, neutropenic patients, anti-TNF therapy
Epidemiology
• in HIV patients starting ART, IRS reported to affect ~10%

Investigations
• IRS is a diagnosis of exclusion
• rule out drug reaction, patient non-adherence, drug resistance

Treatment
• continue HAART therapy in HIV patients with mild-moderate symptoms, but consider discontinuation if symptoms are life-threatening or potentially irreversible
• treat underlying infection; initiate treatment for some infections prior to HAART initiation
• consider starting corticosteroids/NSAIDs to decrease inflammatory response

A Simplified Look at Antibiotics
• general overview see Table 31 for more details

1. Penicillins

2. Cephalosporins (PO/IV)
• 1st generation: cephalexin/cefazolin (mostly GP, some GN)
• 2nd generation: cefuroxime/cefprozil (some GP and some GN, *anaerobes)
• 3rd generation: cefixime/ceftaxime, ceftriaxone (good Streptococcal coverage, mostly GN), and ceftazidime (no GP, mostly GN, Pseudomonas)
• 4th generation: --/cefepime (most GP, most GN, Pseudomonas)

3. Aminoglycosides (GN aerobic bacilli)
• gentamicin
• tobramycin
• amikacin

4. Macrolides (GP, Haemophilus, and atypical bacteria [Legionella, Chlamydia, Mycoplasma])
• erythromycin
• clarithromycin
• azithromycin

5. Fluoroquinolones (GN – although resistance becoming a huge problem)
• ciprofloxacin (+ Pseudomonas)
• norfloxacin (for UTI only)
• respiratory fluoroquinolones (some GP, GN, “atypicals”, Legionella, Mycoplasma, Chlamydia, Mycobacteria)
  ◦ levofloxacin, ofloxacin
  ◦ moxifloxacin (+ anaerobes)

6. Carbapenems (broad coverage: GP, GN, and anaerobes)
• imipenem (+ Pseudomonas)
• meropenem (+ Pseudomonas)
• ertapenem
Antimicrobials

7. Others
- doxycycline/tetracycline (GP, syphilis, Chlamyphila, Rickettsia, Mycoplasma)
- tigecycline (for resistant GP infections, GN, anaerobes, Chlamyphila, Rickettsia, Mycoplasma)
- vancomycin (all GP and C. difficile – the oral form for)
- linezolid (for resistant GP infections)
- daptomycin (for resistant GP infections)
- clindamycin (most GP, GN anaerobes)
- TMP/SMX (most S. aureus including: MRSA, GN aerobes, Pneumocystis)
- nitrofurantoin (GN bacilli, S. saprophyticus, Enterococcus)
- metronidazole (anaerobes including: C. difficile, Trichomonas, Entamoeba)
- treatment for C. difficile: metronidazole OR oral vancomycin; consider both in serious infection

Antimicrobials

Antibiotics

- empiric antibiotic therapy
  - choose antibiotic(s) to cover for most likely and lethal organisms for the type of infection prior to obtaining laboratory results (usually reserved for serious infections)
  - adjust antibiotic(s) based on C&S
    - if causative organism identified, use antibiotic to which organism is sensitive
    - if causative organism not identified, re-evaluate need for ongoing antimicrobial therapy (and continue with empiric antibiotic(s) if indicated)

Reasons for Combination Therapy
- Polymicrobial infection
- Empiric therapy pending culture results
- Synergy for difficult to treat pathogens (e.g. Enterococcus spp. causing endocarditis)
- To prevent emergence of resistance

Figure 20. Mechanism of action of antibiotics

### Introduction to Genetics

#### Terms

- **Penetrance**: extent that a gene is observably expressed in an individual that carries it
- **Expressivity**: extent of gene expression
- **Genetic heterogeneity**: genetic disorder can arise from different allele/locus mutations
- **Phenotypic heterogeneity**: mutations in the same gene resulting in multiple diverse clinical manifestations and degree of severity
- **Imprinting**: epigenetic process that involves methylation or acetylation of DNA, affecting gene expression
- **Uniparental disomy**: two full or partial copies of a chromosome from one parent and no chromosome from the other parent

#### Mendelian Inheritance

- disorders caused by mutation of one or both copies (alleles) of a gene, inherited in one of two patterns
  - autosomal: when disorder is caused by genes on one of 22 pairs of autosomes (chromosomes 1-22)
  - X-linked: when disease is caused by a gene on the X chromosome

#### Triplet Repeat Expansions

- disorder in which trinucleotide repeats in certain genes exceed the normal number and result in altered gene expression or production of an abnormal protein (e.g. Fragile X syndrome, Huntington’s disease)

#### Imprinting Disorders

- imprinted genes are expressed entirely from either the maternal or paternal allele, depending on the gene (parent-of-origin gene expression)
- occur when a mutation disrupts the normally expressed allele of imprinted gene (e.g. Prader-Willi syndrome, Angelman syndrome, Beckwith-Wiedemann syndrome) or through uniparental disomy of the normally silenced allele

#### Mitochondrial Disorders

- disorders caused by mutations of the DNA present in mitochondria or nuclear genes whose protein products are important for mitochondrial function
- inheritance pattern of mitochondrial DNA mutations: mother passes on the defect to all her children; father cannot pass on defect since embryo only receives mitochondria from the mother (in the egg)

#### Copy Number Variation

- difference in the amount of genetic material
  - decrease: deletion of a chromosomal region, leaving only one copy of the genetic material in that region (e.g. 22q11.2 deletion syndrome due to deletion on chromosome 22)
  - increase: duplication of a chromosomal region, resulting in more than two copies of the genetic material in that region (e.g. Potocki-Lupski syndrome due to duplication of chromosome 17p11.2)
- CNVs can be part of normal range of genetic variation
Pedigrees

- diagrams that show the pattern/distribution of phenotypes for a genetic disorder within a family, often across multiple generations

Genetic Testing and Counselling

- microarray analysis
  - array comparative genomic hybridization (CGH): a collection of DNA probes attached to a solid surface to which test DNA hybridizes in order to determine copy number of DNA regions
  - microarray analysis can identify small deletions or duplications of genetic material anywhere in the genome
  - commonly indicated when there is developmental delay OR two or more congenital anomalies
- FISH (fluorescence in situ hybridization): a DNA probe used to identify a gain or loss of chromosomal material
- karyotype: microscopic analysis of chromosomes with a special stain that shows large changes in the number or structure of chromosomes; can detect large CNVs
- Sanger sequencing: the ‘gold-standard’ method for identification of single nucleotide variants in short DNA sequences (e.g. the exons of the gene(s) known to cause suspected syndrome)
- next-generation sequencing: high throughput method to sequence exomes or whole-genomes; useful when genetic syndrome is suspected, but diagnosis is unclear: increasingly used for multi-gene test panels
- prenatal screening
  - offer optional prenatal screening before diagnostic testing
  - first trimester screening (FTS)
    - biochemistry (β-hCG, PAPP-A)
    - US estimate of gestational age and measurement of nuchal translucency
    - screen for trisomy 21 and 18
    - done between 11 and 14 wk, sensitivity=80-85%
  - integrated prenatal screening (IPS)
    - ONTD, trisomy 21 and 18
    - use results from FTS and combine with additional biomarkers completed between 15-21 weeks (inhibin A, unconjugated estradiol, AFP, 2nd trimester β-hCG)
    - improved sensitivity, reduced false positive rate compared to FTS
  - fetal anatomy scan
    - US at 18-20 wk
- newborn screening
  - detect potentially fatal, treatable disorders before symptoms begin to allow for early therapy
  - performed on all newborns in Canada
  - heel puncture to collect blood
  - screens for CF, congenital hypothyroidism, congenital adrenal hyperplasia, SCID, hemoglobinopathies, metabolic diseases, etc.

Whole-Genome Sequencing Expands Diagnostic Utility and Improves Clinical Management in Paediatric Medicine

Genomic Med 2016;1:15012

While the standard of care for neurodevelopmental and congenital malformations is chromosome microarray analysis for copy number variations, whole exome sequencing allows the identification of sequence-level mutations across all known coding genes. Whole genome sequencing has been previously associated with a diagnostic yield of ~25% for neurological disorders or congenital anomalies. A recent study published in Genomic Medicine has demonstrated that whole genome sequencing exceeds other technologies in detecting genetic variants with a 34% diagnostic yield, a four-fold increase in molecular diagnosis relative to chromosome microarray analysis and a two-fold increase relative to all genetic testing protocols. These results suggest that whole genome sequencing may be used as a first-tier molecular test in individuals with development delays and congenital abnormalities, with a higher diagnostic yield than conventional genetic testing and decreased time to genetic diagnosis.
### Dysmorphisms

#### Congenital Anomalies

**Minor and Major Anomalies**
- minor anomaly: an unusual anatomic feature that is of no serious medical or cosmetic consequence to the patient
- major anomaly: anomaly that creates significant medical, surgical, or cosmetic problems for the patient

**Mechanism for Anomalies**
- malformation: results from an intrinsically abnormal developmental process (e.g. polydactyly)
- disruption: results from the extrinsic breakdown of, or interference with, an originally normal developmental process (e.g. amniotic band disruption sequence)
- deformation: alteration of the final form of a structure by mechanical forces (e.g. Potter deformation sequence)
- dysplasia: abnormal development that results in abnormal organization of cells into tissues (e.g. bone dysplasia)

**Multiple Anomalies**
- association: non-random occurrence of multiple independent anomalies that appear together more than would be predicted by chance but are not known to have a single etiology (e.g. VACTERL)
- sequence: related anomalies that come from a single initial major anomaly or precipitating factor that changes the development of other surrounding or related tissues or structures (e.g. Potter sequence or Pierre-Robin sequence)
- syndrome: a pattern of anomalies that occur together and are known or thought to have a single cause (e.g. Down syndrome)

### Approach to the Dysmorphic Child

- congenital abnormalities are the most common cause of infant death in developed countries

**General Approach to the Dysmorphic Child**
- Are the anomalies major or minor?
- What is the mechanism underlying the anomaly?
- Do the anomalies fit as part of an association, sequence, or syndrome?

**History**
- prenatal/obstetrical history (see Obstetrics, OB4) with particular attention to potential teratogenic exposures, development history (see Pediatrics, P22), and past medical history
- complete 3 generation family pedigree: health history, consanguinity, stillbirths, neonatal deaths, specific illnesses, intellectual disability, multiple miscarriages, ethnicity

**Physical Exam**

**Figure 2. Physical exam of the dysmorphic child**
Investigations
- screening for TORCH infections
- serial photographs if child is older
- x-rays for bony abnormalities
- cytogenetic studies
  - karyotype if recognized aneuploidy syndrome
  - chromosomal microarray analysis (array comparative genomic hybridization) if development delay OR two or more congenital anomalies
  - FISH if aneuploidy syndrome (e.g. trisomy 13, 18 or 21) suspected
- biochemistry: various biochemical profiles, specific enzyme assays
- single gene testing, multi-gene panel testing

Management
- prenatal counselling and assessing risk of recurrence
- referral for specialized pediatric or genetic care for symptomatic management
- specific treatments are available for certain metabolic disorders and genetic syndromes
  - metabolic disorders: enzyme replacement therapy, substrate reduction therapy, etc. (e.g. low-protein diet in PKU patients)
  - genetic syndromes: e.g. mTOR inhibitors in tuberous sclerosis

Single Gene Disorders

**CYSTIC FIBROSIS**
- see Respirology, R12 and Pediatrics, P82

**SICKLE CELL DISEASE**
- see Hematology, H20

**DUCHENNE MUSCULAR DYSTROPHY**

**Epidemiology**
- 1:4,000 males

**Etiology**
- one type of muscular dystrophy characterized by progressive skeletal and cardiac muscle degeneration
- X-linked recessive: 1/3 spontaneous mutations, 2/3 inherited mutations
- missing structural protein (dystrophin) → muscle fibre fragility → fibre breakdown → necrosis and regeneration

**Clinical Presentation**
- proximal muscle weakness by age 3, positive Gower's sign, waddling gait, toe walking
- pseudohypertrophy of calf muscles (muscle replaced by fat) and wasting of thigh muscles
- decreased reflexes
- non-progressive delayed motor and cognitive development (dysfunctional dystrophin in brain)
- cardiomyopathy

**Diagnosis**
- molecular genetic studies of dystrophin gene (DMD) (first line)
- family history (pedigree analysis)
- increased CK (50-100x normal) and lactate dehydrogenase
- elevated transaminases
- muscle biopsy, EMG

**Management**
- supportive (e.g. physiotherapy, wheelchairs, braces, prevent obesity
- cardiac health monitoring and early intervention
- bone health monitoring and intervention (vitamin D, bisphosphonates)
- steroids (e.g. prednisone or deflazacort)
- surgical (for scoliosis)
- gene therapy trials underway

**Complications**
- patient usually wheelchair-bound by 12 yr of age
- early flexion contractures, scoliosis, osteopenia of immobility, increased risk of fracture
- death due to pneumonia/respiratory failure or CHF in 2nd-3rd decade
Metabolic Diseases

- inherited disorders of metabolism; often autosomal recessive
- infants and older children may present with FTT or developmental delay
- organellar diseases can present with dysmorphism
  universal newborn screening in Ontario includes metabolic disorders

Initial Investigations

- important to send lab studies at initial presentation in order to facilitate immediate diagnosis and treatment
- check newborn screening results
- electrolytes, ABCs (calculate anion gap, rule out acidosis)
- CBC with differential and smear
- blood glucose (hypoglycemia seen with organic acidemia, fatty acid oxidation defects, and GSDs)
- lactate, ammonium (hyperammonemia with urea cycle defects), plasma Ca²⁺ and Mg²⁺
- routine urinalysis: ketonuria must be investigated
- carnitine levels with acylcarnitine profile
- others: urate, urine nitroprusside, plasma amino acid screen, urine organic acids, CSF glycine, free fatty acids (3-β-hydroxybutyrate ratio >4 in fatty acid oxidation defect)
- storage diseases: urine mucopolysaccharide and oligosaccharide screen

Treatment

- varies according to inborn error of metabolism
- dietary restrictions, supplementation, enzyme replacement therapy, gene therapy, liver transplant, stem cell transplant
PHENYLKETONURIA

Epidemiology
• 1:10,000; autosomal recessive disease

Etiology
• deficiency of phenylalanine hydroxylase prevents conversion of phenylalanine to tyrosine leading to build up of toxic metabolites
• mothers who have PKU may have infants with congenital abnormalities

Clinical Presentation
• baby is normal at birth, then develops a musty odour, eczema, hypertonia, tremors, and mental retardation
• hypopigmentation due to low tyrosine (fair hair, blue eyes)

Management
• PKU screening at birth
• dietary restriction of phenylalanine starting within the first 10 d of life
• duration of dietary restriction controversial – lifelong or until end of puberty; should be resumed during pregnancy to maintain normal phenylalanine levels
• large neutral amino acid (tyrosine) replacement, BH4 enzyme treatment, phenylalanine lyase treatment are other options

GALACTOSEMIA

Epidemiology
• 1:60,000; autosomal recessive disease

Etiology
• most commonly due to deficiency of galactose-1-phosphate uridyltransferase leading to an inability to process lactose/galactose

Clinical Presentation
• signs of liver and renal failure, jaundice, FTT, and cataracts with ingestion of lactose/galactose

Management
• elimination of galactose from the diet (e.g. dairy, breast milk)
• most infants are fed a soy-based diet

Complications
• increased risk of sepsis, especially E. coli
• if the diagnosis is not made at birth, liver and brain damage may become irreversible

**Acronyms**

### DSA, DEXA, CXR, CVP, CVD, CTA, CSF, CNS, BOOP, AV, ARDS
- DSA: Digital Subtraction Angiography
- DEXA: Dual-energy x-ray absorptiometry
- CXR: Chest x-ray
- CVP: Central Venous Pressure
- CVD: Collagen Venous Pressure
- CTA: Computed Tomographic Angiogram
- CSF: Cerebrospinal Fluid
- CNS: Central Nervous System
- BOOP: Bronchitis Obliterans
- AV: Arteriovenous
- ARDS: Acute Respiratory Distress Syndrome

### X-Ray Imaging

#### X-rays
- x-rays, or Roentgen rays, are a form of electromagnetic energy of short wavelength
- as x-ray photons traverse matter, they can be absorbed (a process known as "attenuation") and/or scattered
- the density of a structure determines its ability to attenuate or "weaken" the x-ray beam
  - air < fat < water < bone < metal
- structures that have high at euation (e.g. bone) appear white on the resulting images

#### Plain Films
- x-rays pass through the patient and interact with a detection device to produce a 2-dimensional projection image
- structures closer to the film appear sharper and less magnified
- contraindications: pregnancy (relative)
- advantages: inexpensive, non-invasive, readily available, reproducible, fast
- disadvantages: radiation exposure, generally poor at distinguishing soft tissues

#### Fluoroscopy
- continuous x-rays used for guiding angiographic and interventional procedures, in contrast examinations of the GI tract, and in the OR for certain surgical procedures (e.g. orthopedic, urological)
- on the fluoroscopic image, black and white are reversed so that bone and contrast agents appear dark and radiolucent structures appear light
- advantages: allows for real-time visualization of structures
- disadvantages: increased radiation dose; however, the use of pulsed fluoroscopy has reduced fluoroscopy time by 76% and radiation dose by 64% as compared with continuous fluoroscopy

#### Computed Tomography
- x-ray beam opposite a detector moves in a continuous 360º arc as patient is advanced through the imaging system
- subsequent computer assisted reconstruction of anatomical structures from the axial plane
- atenuation is quantified in Hounsfield units
- subsequent computer assisted reconstruction of anatomical structures from the axial plane
- adjusting the "window width" (range of Hounsfield units displayed) and "window level" (midpoint value of the window width) can maximally visualize certain anatomical structures (e.g. CT chest can be viewed using "lung", "soft tissue", and "bone" settings)
- contraindications: pregnancy (relative) contraindications to contrast agents (e.g. allergy, renal failure)
- advantages: delineates surrounding soft tissues, excellent at delineating bones and identifying lung/ liver masses, may be used to guide biopsies, spiral/helical multidetector CT has fast data acquisition and allows 3D reconstruction, CTA is less invasive than conventional angiography
- disadvantages: high radiation exposure, soft tissue characterization is not as good in comparison with MRI, IV contrast injection, anxiety of patient when going through scanner, higher cost, and less available than plain film

**Calculated using average natural background exposure in Canada (Health Canada: http://www.hc-sc.gc.ca/alt-vi/vyh-vys/environment/expris-eng.php)
Ultrasound

- high-frequency sound waves are transmitted from a transducer and passed through tissues; reflections of the sound waves are picked up by the transducer and transformed into images
- reflection (or “echo”) occurs when the sound waves pass through tissue interfaces of different acoustic densities
- structures are described based on their echogenicity; hyperechoic structures appear bright (U/S reflected) whereas hypoechoic structures appear dark (U/S waves not reflected back but pass through)
- higher U/S frequencies result in greater resolution but greater attenuation (i.e. deeper structures more difficult to visualize)
- artifacts: acoustic shadowing refers to the echo-free area located behind an interface that strongly reflects (e.g. tissue/air) or absorbs (e.g. tissue/bone) sound waves; enhancement refers to the increase in reflection amplitude (i.e. increased brightness) from objects that lie below a weakly attenuating structure (e.g. cyst)
- Duplex scan: grey-scale image that utilizes the Doppler effect to visualize the velocity of blood flow past the transducer
- Colour Doppler: assigns a colour based on the direction of blood flow (i.e. red = toward transducer, blue = away)
- advantages: relatively low cost, non-invasive, no radiation, real time imaging, may be used for guided biopsies many different imaging planes (axial, sagittal), determines cystic versus solid
- disadvantages: highly operator-dependent, air in bowel may prevent imaging of midline structures in the abdomen, may be limited by patient habitus, poor for bone evaluation

Magnetic Resonance Imaging

- non-invasive imaging technique that does not use ionizing radiation and able to produce images in virtually any plane
- patient is placed in a magnetic field; protons (H⁺) align themselves along the plane of magnetization due to intrinsic polarity. A pulsed radiofrequency beam is subsequently turned on and deflects all the protons off their aligned axes due to absorption of energy from the radiofrequency beam. When the radiofrequency beam is turned off, the protons return to their pre-excitation axis, giving off the energy they absorbed. This energy is measured with a detector and interpreted by software to generate MR images
- the MR image reflects the signal intensity picked up by the receiver. This signal intensity is dependent on:
  1. hydrogen density: tissues with low hydrogen density (e.g. cortical bone, lung) generate little to no MR signal compared to tissues with high hydrogen density (e.g. water)
  2. magnetic relaxation times (T1 and T2): reflect quantitative alterations in MR signal strength due to intrinsic properties of the tissue and its surrounding chemical and physical environment

</tr>
</thead>
<tbody>
<tr>
<td>Diffusion-Weighted Imaging</td>
<td>Contrast dependent on the molecular motion of water Decreased diffusion is hyper intense (bright), whereas increased diffusion is hypointense (dark)</td>
<td>Neuroradiology</td>
<td>Sensitive for detection of acute ischemic stroke and differentiating an acute stroke from other neurologic pathologies Acute infarction appears hyperintense Abscess collections also show restricted diffusion</td>
</tr>
<tr>
<td>T1-Weighted</td>
<td>Fluid is hypointense (dark) and fat is hyperintense (bright)</td>
<td>Body soft tissues</td>
<td>Often considered an anatomic scan since they provide a reference for functional imaging</td>
</tr>
<tr>
<td>T2-Weighted</td>
<td>Fluid is hyperintense (bright) and fat is hypointense (dark)</td>
<td>Body soft tissues</td>
<td>Often considered a pathologic scan since they will highlight edematous areas associated with certain pathologies</td>
</tr>
</tbody>
</table>

Positron Emission Tomography Scans

- non-invasive technique that involves exposure to ionizing radiation (~7 mSv)
- nuclear medicine imaging technique that produces images of functional processes in the body
- current generation models integrate PET and CT technologies into a single imaging device (PET-CT) that collects both anatomic and functional information during a single acquisition
- positron-producing radioisotopes, such as ¹⁸FDG, are chemically incorporated into a metabolically active molecule (e.g. glucose). These are then injected into the patient, travel to the target organ, and accumulate in tissues of interest. As the radioactive substance begins to decay, gamma rays are produced, and are then detected by the PET scanner
- contraindications: pregnancy
- advantages: shows metabolism and physiology of tissues (not only anatomic); in oncology, allows for diagnosis staging, and restaging; has predictive and prognostic value; can evaluate cardiac viability
- disadvantages: cost, ionizing radiation
# Contrast Enhancement

## Table 2. Contrast Agents

<table>
<thead>
<tr>
<th>Imaging Modality</th>
<th>Types</th>
<th>Advantages</th>
<th>Disadvantages</th>
<th>Contraindications</th>
</tr>
</thead>
<tbody>
<tr>
<td>X-Ray/CT</td>
<td>1. Barium (oral or rectal)</td>
<td>Radio-opaque substance that helps to delineate intraluminal anatomy; may demonstrate patency, lumen integrity, or large filling defects</td>
<td>Previous adverse reaction to contrast; barium enema is contraindicated in toxic megacolon, acute colitis, and suspected perforation</td>
<td></td>
</tr>
<tr>
<td></td>
<td>2. Iodine (IV injection)</td>
<td>Delineates intraluminal anatomy; may demonstrate patency, lumen integrity, or large filling defects; under fluoroscopy, may also give information on function of an organ</td>
<td>Risk of nephrogenic systemic fibrosis in patients with end-stage renal disease; Previous adverse reaction to contrast, renal failure, DM, pregnancy, multiple myeloma, severe heart failure and dehydration; eGFR &lt;60 may require preventative measures and follow-up</td>
<td></td>
</tr>
<tr>
<td>MRI</td>
<td>Gadolinium-Chelates (IV injection)</td>
<td>Shortens T1 relaxation time, thereby increasing signal intensity in T1-weighted sequences; gadolinium has some effect on T2-relaxation time; highlights highly vascular structures (e.g. tumours)</td>

<td>Previous adverse reaction to contrast or if end-stage renal disease (relative contraindication)</td>
</tr>
<tr>
<td>U/S</td>
<td>Microbubbles (IV injection)</td>
<td>Since gas is highly echogenic, the microbubbles allow for echo-enhancement of a tissue</td>
<td>Contraindicated in individuals with right-to-left cardiac shunts or people with known hypersensitivity reactions</td>
<td></td>
</tr>
</tbody>
</table>

## Chest Imaging

### Chest X-Ray

#### Standard Views
- **PA**: anterior chest against film plate to minimize magnification of the heart size
- **lateral**: better visualization of retrocardiac space and thoracic spine (more sensitive at picking up pleural effusions)
- Helps localize lesions when combined with PA view
- **AP**: for bedridden patients (generally a lower quality film than PA because of enlarged cardiac silhouette)
- **lateral decubitus**: to assess for pleural effusion and pneumothorax in bedridden patients; however, POCUS can also be utilized for both of these purposes
- **lordotic**: angled beam allowing better visualization of apices normally obscured by the clavicles and anterior ribs

![CXR views](image.png)  
Figure 1. CXR views

### Approach to CXR

#### Basics
- **ID**: patient name, MRN, sex, age
- **date of exam**
- **markers**: right and/or left
- **technique**: view (e.g. PA, AP, lateral), supine or erect
- **indications for the study**
- **comparison**: date of previous study for comparison (if available)
- **quality of film**: inspiration (6th anterior and 10th posterior ribs should be visible), penetration (thoracic spine should be visible) and rotation (clavicles vs. spinous process)
Analysis

- tubes and lines: check position and be alert for pneumothorax or pneumomediastinum
- soft tissues: neck, axillae, pectoral muscles, breasts/nipples, chest wall
  - nipple markers can help identify nipples (may mimic lung nodules)
  - amount of soft tissue, presence of masses and air (subcutaneous emphysema)
- abdomen (see Abdominal Imaging, MI10)
  - free air under the diaphragm, air-fluid levels, distention in small and large bowels
  - herniation of abdominal contents (i.e. diaphragmatic hernia)
- bones: C-spine, thoracic spine, shoulders, ribs, sternum, clavicles
  - lytic and blastic lesions and fractures
- mediastinum: trachea, heart, great vessels
  - cardiomegaly (cardiothoracic ratio >0.5), tracheal shift, tortuous aorta, widened mediastinum
- hila: pulmonary vessels, mainstem and segmental bronchi, lymph nodes
  - comment on abnormal lung opacity, pleural effusions or thickening
  - right hemidiaphragm usually higher than left due to liver
- lungs: lung parenchyma, pleura, diaphragm
  - tend to be lower right
- abdomen (see Abdominal Imaging, MI10)
  - free air under the diaphragm, air-fluid levels, distention in small and large bowels
  - herniation of abdominal contents (i.e. diaphragmatic hernia)
- bones: C-spine, thoracic spine, shoulders, ribs, sternum, clavicles
  - lytic and blastic lesions and fractures
- mediastinum: trachea, heart, great vessels
- cardiomegaly (cardiothoracic ratio >0.5), tracheal shift, tortuous aorta, widened mediastinum
- hila: pulmonary vessels, mainstem and segmental bronchi, lymph nodes
  - comment on abnormal lung opacity, pleural effusions or thickening
  - right hemidiaphragm usually higher than left due to liver
  - right vs. left hemidiaphragm can be discerned on lateral CXR due to heart resting directly on left hemidiaphragm
- please refer to Toronto Notes website for supplementary material on how to approach a CXR

Anatomy

Localizing Lesions for Parenchymal Lung Disease

- silhouette sign: when two objects of the same radiolucency contact each other, they become indistinguishable on imaging and result in the loss of normal interfaces. It can be used to identify lung pathology (consolidation, atelectasis, mass) and localize disease to specific lung segments. The silhouette sign is not only used in the chest, but can also be an aid to interpreting imaging studies throughout the body
- spine sign: on lateral films, vertebral bodies should appear progressively radiolucent as one moves down the thoracic vertebral column; if they appear more radio-opaque, it is an indication of pathology (e.g. consolidation in overlying left lower lobe)
- air bronchogram: branching pattern of air-filled bronchi on a background of fluid-filled airspaces

### Table 3. Localization Using the Silhouette Sign

Lung Abnormalities

Atelectasis
- pathogenesis: collapse of alveoli due to restricted breathing, blockage of bronchi, external compression, or poor surfactant
- findings
  - increased opacity of involved segment/lobe, vascular crowding, silhouette sign, air bronchograms
  - volume loss: fissure deviation, hilar/mediastinal displacement, diaphragm elevation
  - compensatory hyperinflation of remaining normal lung
- differential diagnosis
  - obstructive (most common): air distal to obstruction is reabsorbed causing alveolar collapse
    - post-surgical, endobronchial lesion, foreign body, inflammation (granulomatous infections, pneumoconiosis, sarcoidosis, radiation injury), or mucous plug (cystic fibrosis)
  - compressive
  - tumour: bulla, effusion, enlarged heart, lymphadenopathy
  - traction (cicatrization): due to scarring, which distorts alveoli and contracts the lung
  - adhesive: due to lack of surfactant
    - hyaline membrane disease, prematurity
- passive (relaxation): a result of air or fluid in the pleural space
  - pleural effusion, pneumothorax
- management: in the absence of a known etiology, persisting atelectasis must be investigated (i.e. CT thorax) to rule out a bronchogenic carcinoma

**Consolidation**
- pathogenesis: fluid (water, blood), inflammatory exudates, protein, or tumour in alveoli
- findings
  - air bronchograms: lucent branching bronchi visible through opacification
  - airspace nodules: fluffy, patchy, poorly defined margins with later tendency to coalesce, may take on lobar or segmental distribution
  - silhouette sign
- differential diagnosis
  - fluid: pulmonary edema, blood (trauma, vasculitis, bleeding disorder, pulmonary infarct)
  - inflammatory exudates: bacterial infections, TB, allergic hypersensitivity alveolitis, BOOP, allergic bronchopulmonary aspergillosis, aspiration, sarcoidosis
  - protein: pulmonary alveolar proteinosis
  - tumour: bronchoalveolar carcinoma, lymphoma
- management: varies depending on the pattern of consolidation, which can suggest different etiologies; should also be done in the context of clinical picture

**Interstitial Disease**
- pathogenesis: pathological process involving the interlobular connective tissue (i.e. “scaffolding of the lung”)
- findings
  - linear: fine lines caused by thickened connective tissue septae
    - Kerley A: long thin lines in upper lobes
    - Kerley B: short horizontal lines extending from the lateral lung margin
    - Kerley C: diffuse linear pattern throughout lung
  - nodular: 1-5 mm well-defined nodules distributed evenly throughout lung
  - reticular: parenchyma replaced by thin-walled cysts suggesting extensive destruction of pulmonary tissue and fibrosis
    - seen in IPF, asbestosis, and CVD
  - reticulonodular: combination of reticular and nodular patterns
- differential diagnosis
  - occupational/environmental exposure
    - inorganic: asbestosis, coal miner’s pneumoconiosis, silicosis, berylliosis, talc pneumoconiosis
    - organic: hypersensitivity pneumonitis, bird fancier’s lung, farmer’s lung (mouldy hay), and other organic dust
    - autoimmune: CVD (e.g. rheumatoid arthritis, scleroderma, SLE, polymyositis, mixed connective tissue disease), IB, celiac disease, vasculitis
    - drug-related: antibiotics (cephalosporins, nitrofurantoin), NSAIDs, carbamazepine, fluoxetine, amiodarone, chemotherapy (methotrexate), heroin, cocaine, methadone
    - infections: non-tuberculous mycobacteria, aspergillosis, aspiration, sarcoidosis
    - neoplastic: carcinoma, lymphoma, sarcoma, mesothelioma, pulmonary varix, granulomatous disease (e.g. sarcoidosis)
    - vascular: AV fistula, pulmonary varix (dilated pulmonary vein), infarct, embolism
    - idiopathic: hypersensitivity pneumonitis, IPF, BOOP
- management: high-resolution CT thorax and biopsy
- for Causes of Interstitial Lung Disease Classified by Distribution see Respirology, R13
- management: high-resolution CT thorax and biopsy

**Pulmonary Nodule**
- findings: round opacity ± silhouette sign
  - note: do not mistake nipple shadows for nodules; if in doubt, repeat CXR with nipple markers
- differential diagnosis
  - extrapulmonary density: nipple, skin lesion, electrode, pleural mass, bony lesion
  - solitary nodule
    - tumour: carcinoma, hamartoma, metastasis, bronchial adenoma
    - inflammation: histoplasmosis, tuberculosis, coccidioidomycosis
    - vascular: AV fistula, pulmonary varix (dilated pulmonary vein), infarct, embolism
  - multiple nodules: metastases, abscess, granulomatous lung disease (TB, fungal, sarcoma, rheumatoid nodules, silicosis, GPA)
- management: clinical information and CT appearance determine level of suspicion of malignancy
  - if high probability of malignancy, invasive testing (fine needle aspiration, transbronchial/thoracoscopic biopsy) is indicated
  - if low probability of malignancy, repeat CXR or CT in 1-3 mo and then every 6 mo for 2 yr; if no change, then >99% chance benign

Pulmonary Vascular Abnormalities

Pulmonary Edema
- Pathogenesis: fluid accumulation in the airspaces of the lungs
- Findings
  - Vascular redistribution/enlargement, cephalization, pleural effusion, cardiomegaly (may be present in cardiogenic edema and fluid overloaded states)
  - Fluid initially collects in interstitium
  - Loss of definition of pulmonary vasculature
  - Peribronchial cuffing
  - Kerley B lines
  - Reticulonodular pattern
  - Thickening of interlobar fissures
- As pulmonary edema progresses, fluid begins to collect in alveoli causing diffuse airspace disease often in a “bat wing” or “butterfly” pattern in perilobar regions with tendency to spare the outermost lung fields
- Differential diagnosis: cardiogenic (e.g. CHF), renal failure, volume overload, non-cardiogenic (e.g. ARDS)

Pulmonary Embolism
- Pathogenesis: arterial blockage in the lungs due to emboli from pelvic or leg veins, rarely from PICC lines, ports, air, fat, or amniotic fluid (difficult to diagnose on imaging except by combination of clinical history and CXR and CT findings of ARDS)
- Findings
  - CXR: Westermark sign (localized pulmonary oligemia), Hampton’s hump (triangular peripheral infarct), enlarged right ventricle and right atrium, atelectasis, pleural effusion, and rarely pulmonary edema
  - Definitive imaging study: CT pulmonary angiography to look for filling defect in contrast-filled pulmonary arteries (emboli can be seen up to 4th order arterial branching)
- V/Q scan: not a diagnostic study

Pleural Abnormalities

Pleural Effusion

Table 6. Sensitivity of Plain Film Views for Pleural Effusion

<table>

</tr>
<tr>
<td>PA</td>
<td>200 mL</td>
</tr>
<tr>
<td>Supine</td>
<td>Diffuse haziness</td>
</tr>
</tbody>
</table>

- A horizontal fluid level is seen only in a hydropneumothorax (i.e. both fluid and air within pleural cavity)
- Effusion may exert mass effect, shift trachea and mediastinum to opposite side, or cause atelectasis of adjacent lung
- U/S is superior to plain film for detection of small effusions and may also aid in thoracentesis, and POCUS is now standard of care in acute situations
- Fluid level >1 cm on lateral decubitus film is indication to perform thoracentesis
Pneumothorax
• pathogenesis: gas/air accumulation within the pleural space resulting in separation of the lung from the chest wall
• findings
  • upright chest film allows visualization of visceral pleura as curvilinear line paralleling chest wall
  • separating partially collapsed lung from pleural air
  • more obvious on expiratory (increased contrast between lung and air) or lateral decubitus films (air collects superiorly)
  • more difficult to detect on supine film; look for the “deep (costophrenic) sulcus” sign, double diaphragm sign (dome and anterior portions of diaphragm outlined by lung and pleural air, respectively), hyperlucent hemithorax, sharpening of adjacent mediastinal structures
  • mediastinal shift may occur if tension pneumothorax
• differential diagnosis: spontaneous (tall and thin males, smokers), iatrogenic (lung biopsy, ventilation, CVP line insertion), trauma (associated with rib fractures), emphysema, malignancy, honeycomb lung
• management: needle decompression or chest tube insertion, repeat CXR to ensure resolution

Asbestos
• asbestos exposure may cause various pleural abnormalities including benign plaques (most common; these may calcify), diffuse pleural fibrosis, effusion, and malignant mesothelioma

Mediastinal Mass
• the mediastinum is divided into four compartments; this provides an approach to the differential diagnosis of a mediastinal mass
• anterior border formed by the sternum and posterior border by the heart and great vessels
  • 4 Ts: see sidebar
  • cardiophrenic angle mass differential: thymic cyst, epicardial fat pad, foramen of Morgagni hernia
• middle border (extending behind anterior mediastinum to a line 1 cm posterior to the anterior border of the thoracic vertebral bodies)
  • esophageal carcinoma, esophageal duplication cyst, metastatic disease, lymphadenopathy (all causes), hiatus hernia, bronchogenic cyst
• posterior border (posterior to the middle line described above)
  • neurogenic tumour (e.g. neurofibroma, schwannoma), multiple myeloma, pheochromocytoma, neuroenteric cyst, thymic duct cyst, lateral meningocele, Bochdalek hernia, extramedullary hematopoiesis
• superior boundaries (superiorly by thoracic inlet, inferiorly by plane of the sternal angle, anteriorly by manubrium, posteriorly by T1-T4, laterally by pleura)
• in addition, any compartment may give rise to lymphoma, lung cancer, aortic aneurysm or other vascular abnormalities, abscess, or hematoma

Enlarged Cardiac Silhouette
• heart borders
  • on PA view, right heart border is formed by right atrium; left heart border is formed by left atrium and left ventricle
  • on lateral view, anterior heart border is formed by right ventricle; posterior border is formed by left atrium (superior to left ventricle) and left ventricle
• cardiothoracic ratio = greatest transverse dimension of the central shadow relative to the greatest transverse dimension of the thoracic cavity
• using a good quality erect PA chest film in adults, cardiothoracic ratio of >0.5 is abnormal
• differential of ratio >0.5
  • cardiomegaly (myocardial dilatation or hypertrophy)
  • pericardial effusion
  • poor inspiratory effort/low lung volumes
  • pectus excavatum
• ratio <0.5 does not exclude enlargement (e.g. cardiomegaly + concomitant hyperinflation)
• pericardial effusion: globular heart with loss of indentations on left mediastinal border
• RA enlargement: increase in curvature of right heart border and enlargement of SVC
• LA enlargement: flattening of left heart border; increased opacity of lower right side of cardiovascular shadow (double heart border); elevation of left main bronchus (specifically, the upper lobe bronchus on the lateral film), distance between left main bronchus and “double” heart border >7 cm, splayed carina (late sign)
• RV enlargement: elevation of cardiac apex from diaphragm; anterior enlargement leading to loss of retrosternal air space on lateral; increased contact of right ventricle against sternum
• LV enlargement: rounding of the cardiac apex; displacement of left cardiac boarder leftward, inferiorly, and posteriorly
**Tubes, Lines, and Catheters**

- ensure appropriate placement and assess potential complications of lines and tubes
- avoid mistaking a line/tube for pathology (e.g. oxygen rebreather mask for pneumothoraces)

**Central Venous Catheter**
- used for fluid and medication administration, vascular access for hemodialysis, and CVP monitoring
- tip must be located proximal to right atrium to prevent inducing arrhythmias or perforating wall of atrium
  - if monitoring CVP, catheter tip must be proximal to venous valves
  - tip of well-positioned central venous catheter projects over silhouette of SVC in a zone demarcated superiorly by the anterior first rib end and clavicle, and inferiorly by top of RA
- course should parallel course of SVC; if appears to bend as it approaches wall of SVC or appears perpendicular, catheter may damage and ultimately perforate wall of SVC
- complications: pneumothorax, bleeding (mediastinal, pleural), air embolism

**Endotracheal Tube**
- frontal chest film: tube projects over trachea and shallow oblique or lateral chest radiograph will help determine position in 3 dimensions
- progressive gaseous distention of stomach on repeat imaging is concerning for esophageal intubation
- tip should be located 4 cm above tracheal carina (avoids bronchus intubation and vocal cord irritation)
- maximum inflation diameter <3 cm to avoid necrosis of tracheal mucosa and rupture; ensure diameter of balloon is less than tracheal diameter above and below balloon
- complications: aspiration (parenchymal opacities), pharyngeal perforation (subcutaneous emphysema, pneumomediastinum, mediastinitis)

**Nasogastric Tube**
- tip and sideport should be positioned distal to esophagogastric junction and proximal to gastric pylorus
- radiographic confirmation of tube is mandatory because clinical techniques for assessing tip position may be unreliable
- complications: aspiration (parenchymal opacities), intracranial perforation (trauma patients), pneumothorax

**Swan-Ganz Catheter**
- to monitor pulmonary capillary wedge pressure and to measure cardiac output for suspected LV dysfunction
- tip should be positioned within right or left main pulmonary arteries or in one of their large, lobar branches
- if tip is located more distally, increased risk of prolonged pulmonary artery occlusion resulting in pulmonary infarction or, rarely, pulmonary artery rupture
- complications: pneumothorax, bleeding (mediastinal, pleural), air embolism

**Chest Tube**
- in dorsal and caudal portion of pleural space to evacuate fluid
- in ventral and cephalad portions of pleural space to evacuate pneumothoraces
- tube may lie in fissure as long as functioning
- complications: lung perforation (mediastinal opacities)

---

### Abdominal Imaging

#### Abdominal X-Ray

**Indications**
- acute abdomen: bowel perforation, toxic megacolon, bowel ischemia, small bowel obstruction, large bowel obstruction
- chronic symptoms: constipation, calcifications (gallstones, renal stones, urinary bladder stones, etc.)
- not useful in: GI bleeds, chronic anemia, vague GI symptoms

**Anatomy**
- abdomen divided into 2 cavities
  - peritoneal cavity: lined by peritoneum that wraps around most of the bowel, the spleen, and most of the liver; forms a recess lateral to both the ascending and descending colon (paracolic gutters)
  - retroperitoneal cavity: contains several organs situated posterior to the peritoneal cavity; the contour of these can often be seen on radiographs

### Approach to Abdominal X-Ray

- **mnemonic: “Free ABDO”**
  - **“Free”: free air and fluid**
    - free fluid
      - small amounts of fluid: increased distance between lateral fat stripes and adjacent colon may indicate free peritoneal fluid in the paracolic gutters
      - large amounts of fluid: diffuse increased opacification on supine film; bowel floats to centre of anterior abdominal wall
    - ascites and blood (hemoperitoneum) are the same density on the radiograph, and therefore, cannot be differentiated
    - free intraperitoneal air suggests rupture of a hollow viscus (anterior duodenum, transverse colon), penetrating trauma, or recent (<7 d) surgery
  - **“A”: air in the bowel (can be normal, ileus, or obstruction)**
    - volvulus – twisting of the bowel upon itself; from most to least common:
      - sigmoid: ‘coffee bean’ sign (massively dilated sigmoid projects to right or mid-upper abdomen) with proximal dilation
      - cecal: massively dilated bowel loop projecting to left or mid-upper abdomen with small bowel dilation
      - gastric: rare
    - transverse colon: rare (usually young individuals)
    - small bowel: “corkscrew sign” (rarely diagnosed on plain films, seen best on CT)
    - toxic megacolon
      - manifestation of fulminant colitis
      - extreme dilatation of colon (>6.5 cm) with mucosal changes (e.g. foci of edema, ulceration, pseudopolyps), loss of normal haustral pattern
  - **“B”: bowel wall thickening**
    - increased soft tissue density in bowel wall, thumb-like indentations in bowel wall (“thumb-printing”), or a picket-fence appearance of the valvulae conniventes (“stacked coin” appearance)
    - may be seen in IBD, infection, ischemia, hypoproteineemic states, and submucosal hemorrhage
  - **“D”: densities**
    - bones: look for gross abnormalities of lower ribs, vertebral column, and bony pelvis
    - abnormal calcifications: approach by location
      - RUQ: renal stone, adrenal calcification, gallstone, porcelain gallbladder
      - RLQ: ureteral stone, appendicolith, gallstone ileus
      - LUQ: renal stone, adrenal calcification, tail of pancreas
      - LLQ: ureteral stone
      - central: aorta/aortic aneurysm, pancreas, lymph nodes
      - pelvis: phleboliths (i.e. calcified veins), uterine fibroids, bladder stones
  - **“O”: organs**
    - kidney, liver, gallbladder, spleen, pancreas, urinary bladder, psoas shadow
    - outlines can occasionally be identified because they are surrounded by more lucent fat, but all are best visualized with other imaging modalities (CT, MRI)

---

**Figure 16. Normal AXRs:** (left) supine anteroposterior AXR, (middle) upright anteroposterior AXR, and (right) left lateral decubitus AXR
Table 9. Adynamic Ileus vs. Mechanical Obstruction

<table>
<thead>
<tr>
<th>Feature</th>
<th>Adynamic Ileus</th>
<th>Mechanical Obstruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Calibre of Bowel Loops</td>
<td>Normal or dilated</td>
<td>Usually dilated</td>
</tr>
<tr>
<td>Air-Fluid Levels</td>
<td>Same level in the same single loop</td>
<td>Multiple air fluid levels giving “step ladder” appearance, dynamic (indicating peristalsis present), “string of pearls” (row of small gas accumulations in the dilated valvulae conniventes)</td>
</tr>
<tr>
<td>Distribution of Bowel Gas</td>
<td>Air throughout GI tract is generalized or localized In a localized ileus (e.g. pancreatitis, appendicitis), dilated “sentinel loop” remains in the same location on serial films, usually adjacent to the area of inflammation</td>
<td>Dilated bowel up to the point of obstruction (i.e. transition point)</td>
</tr>
</tbody>
</table>

**Abdominal Computed Tomography**

- indications for plain CT: renal colic, hemorrhage
- indications for CT with contrast
  - IV contrast given immediately before or during CT to allow identification of arteries and veins
  - portal venous phase: indicated for majority of cases
  - biphasic (arterial and portal venous phases): liver, pancreas, bile duct tumours
  - caution: contrast allergy (may premedicate with steroids and antihistamine)
  - contraindication: impaired renal function (based on eGFR)
- oral contrast: barium or water-soluble (water soluble if suspected perforation) given in most cases to demarcate GI tract
- rectal contrast: given for investigation of colonic lesions

**Approach to Abdominal Computed Tomography**

- look through all images in gestalt fashion to identify any obvious abnormalities
- look at each organ/structure individually from top to bottom, evaluating size and shape of each area of increased or decreased density
- evaluate the following:
  - soft tissue window
    - liver, gallbladder, spleen and pancreas
    - adrenals, kidneys, ureters, and bladder
    - stomach, duodenum, small bowel mesentery, and colon/appendix
  - retroperitoneum: aorta, vena cava, and mesenteric vessels; look for adenopathy in vicinity of vessels
  - peritoneal cavity for fluid or masses
  - abdominal wall and adjacent soft tissue
  - lung window
    - visible lung (bases)
  - bone window
    - vertebrae, spinal cord, and bony pelvis

**Biliary vs. Portal Venous Air**

- "Go with the flow": air follows the flow of bile or portal venous blood
- Biliary air is most prominent centrally over the liver
- Portal venous air is most prominent peripherally

**Table 8. Abnormal Air on Abdominal X-Ray**

**Conclusion**

93.8%, 97.7%) and OC has a sensitivity of 94.7% (95% CI 90.4%, 97.2%) for the detection of CRC. CTC has a sensitivity of 96.1% (95% CI 93.8%, 97.7%) and OC has a sensitivity of 94.7% (95% CI 90.4%, 97.2%) for the detection of CRC.

**Purpose**

To assess the sensitivity of computed tomography (CT) colonography and optical colonoscopy (OC) for colorectal cancer (CRC) detection.

**Methods**

Systematic review and meta-analysis of diagnostic studies evaluating CT colonography detection of CRC based on a prior eligibility criteria, in particular requiring both OC and histological confirmation of disease. Studies that also assessed true-positive and false-negative diagnoses with OC were used to calculate OC sensitivity. Sensitivity of CTC and OC for CRC was the main outcome.

**Results**

49 studies on 11,151 patients undergoing diagnostic study for detection of CRC were included. CTC has a sensitivity of 96.1% (95% CI 93.8%, 97.7%) and OC has a sensitivity of 94.7% (95% CI 90.4%, 97.2%) for the detection of CRC.

**Conclusion**

CTC is highly sensitive for the detection of CRC and may be a better modality for the initial investigation of suspected CRC, assuming reasonable specificity.
CT and Bowel Obstruction
- cause of bowel obstruction rarely found on plain films; CT is best choice for imaging
- the "3 6,9" rule is a very useful guide to determining when the bowel is dilated; the maximum diameter of the bowel is 3 cm for small bowel, 6 cm for large bowel, and 9 cm for cecum; this can also be useful to distinguish small and large bowel, and to assess for ‘impending’ cecal perforation (e.g. post-untreated Ogilvie’s syndrome)
- closed-loop obstruction: an obstruction in two locations (usually small bowel) creating a loop of bowel segment obstructed both proximally and distally; complications (e.g. ischemia, perforation, necrosis) may occur quickly

CT Colonography (virtual colonoscopy)
- emerging imaging technique for evaluation of intraluminal colonic masses (i.e. polyps, tumours)
- two CT scans of the abdomen (prone and supine) after the instillation of carbon dioxide into a prepped colon
- computer reconstruction of 2D CT images into a 3D intraluminal view of the colon
- lesions seen on 3D images correlated with 2D axial images
- indications: surveillance in low-risk patients, incomplete colonoscopy, staging of obstructing colonic lesions

Contrast Studies

</tbody>
</table>
Specific Visceral Organ Imaging

Liver
- U/S: assessment of cysts, abscesses, tumours, biliary tree
- CT ± IV: most popular procedure for imaging the liver parenchyma (primary liver tumours, metastases, cysts, abscesses, trauma, cirrhosis)
- MR: also excellent in evaluation of primary liver tumours, liver metastases, and other parenchymal conditions, and is particularly helpful in differentiating common benign hepatic hemangiomas from primary liver tumours and metastases
- elastography: measures shear wave velocity by U/S (Fibroscan) or MRI (MR elastography) to non-invasively quantify liver fibrosis
- findings
  - advanced cirrhosis: liver small and irregular (fibrous scarring, segmental atrophy, regenerating nodules)
  - portal HTN: increased portal vein diameter, collateral veins, splenomegaly (≥12 cm), portal vein thrombosis, recanalization of the umbilical vein
  - porto-systemic shunts: caput medusa, esophageal varices, spontaneous spleno-renal shunt
- U/S: cirrhosis appears nodular and hyperechoic with irregular areas of atrophy of the right lobe and hypertrophy of the caudate or left lobes
- CT: fatty infiltration appears hypodense
- in order to be visualized, some masses require contrast
- upon identifying a liver lesion on imaging (e.g. U/S), the follow-up imaging modality should be CT or MR. CT would be four-phase non-contrast, arterial, venous, and delayed to distinguish the common benign liver lesion hemangioma from other tumours

Table 11. Imaging of Liver Masses

<td>Usually low attenuation on contrast-enhanced scan</td>
</tr>
</tbody>
</table>

Spleen
- U/S, CT, nuclear medicine scan (nuclear medicine only to distinguish ectopic splenic tissue from enhancing tumours)
- CT for splenic trauma (hemorrhage)

Pancreas
- tumours
  - U/S: mass is more echogenic than normal pancreatic tissue
  - CT: preferred modality for diagnosis/staging
- ductal dilation secondary to stone/tumour
- MRCP: imaging of ductal system using MRI cholangiography; no therapeutic potential
- ERCP: endoscope to inject dye into the biliary tree and x-ray imaging to assess pancreatic and biliary ducts; therapeutic potential (stent placement, stone retrieval); acute pancreatitis is a complication in 5% of diagnostic procedures and 10% of therapeutic procedures

Biliary Tree
- U/S: bile ducts usually visualized only if dilated, secondary to obstruction (e.g. choledocholithiasis, benign stricture mass)
- CT: dilated intrahepatic ductules seen as branching, tubular structures following pathway of portal venous system
- MRCP, ERCP, PTC: further evaluation of obstruction and possible intervention

Figure 18. ERCP: biliary tree
**Acute Cholecystitis**
- Pathogenesis: inflammation of gallbladder resulting from sustained gallstone impaction in cystic duct or, in the case of acalculous cholecystitis, due to gallbladder ischemia or cholestasis (see *General Surgery, GS47*)
- Best imaging modality: U/S (best sensitivity and specificity), nuclear medicine (HIDA scan can help diagnose cases of acalculous or chronic cholecystitis)
- Findings: Most sensitive findings are presence of gallstones and positive sonographic Murphy's sign (tenderness from pressure of US probe over visualized gallbladder). Secondary findings include thickened gallbladder wall (>3 mm), dilated gallbladder and pericholecystic fluid.
- Management: admit, NPO, IVF analgesia, cefazolin, early laparoscopic cholecystectomy

**Acute Appendicitis**
- Pathogenesis: luminal obstruction → bacterial overgrowth → inflammation/swelling → increased pressure → localized ischemia → gangrene/perforation → localized abscess or peritonitis (see *General Surgery, GS27*)
- Best imaging modality: U/S or CT
- Findings:
  - U/S: thick-walled appendix, appendicolith, dilated fluid-filled appendix, non-compressible; may also demonstrate other causes of RLQ pain (e.g. ovarian abscess, IBD, ectopic pregnancy)
  - CT: enlargement of appendix (>6 mm in outer diameter), enhancement of appendiceal wall, adjacent inflammatory stranding, appendicolith; also facilitates percutaneous abscess drainage management: admit, NPO, IVF, analgesia, cefazolin + metronidazole, appendectomy

**Acute Diverticulitis**
- Pathogenesis: erosion of the intestinal wall (most commonly rectosigmoid) by increased intraluminal pressure or ininspired food particles → inflammation and focal necrosis → micro- or macroscopic perforation (see *General Surgery, GS31*)
- Best imaging modality: CT although U/S is sometimes used
- Contrast: oral and rectal contrast given before CT to opacify bowel
- Findings:
  - Cardinal signs: thickened wall, mesenteric infiltration, gas-filled diverticula, abscess
  - CT can be used for percutaneous abscess drainage before or in lieu of surgical intervention
  - Sometimes difficult to distinguish from perforated cancer (therefore send abscess fluid for cytology and follow-up with colonoscopy)
  - If chronic, may see fistula (most common to bladder) or sinus tract (linear or branching structures)
- Management: ranges from antibiotic treatment to surgical intervention; can use imaging to follow progression

**Acute Pancreatitis**
- Pathogenesis: activation of proteolytic enzymes within pancreatic cells leading to local and systemic inflammatory response (see *Gastroenterology, G44*); a clinical/biochemical diagnosis
- Best imaging modality: imaging used to support diagnosis and evaluate for complications (diagnosis cannot be excluded by imaging alone)
  - U/S good for screening and follow-up
  - CT is useful in advanced stages and in assessing for complications (1st line imaging test)
- Findings:
  - U/S: hypoechoic enlarged pancreas (if ileus present, gas obscures pancreas)
  - CT: enlarged pancreas, edema, stranding changes in surrounding fat with indistinct fat planes, mesenteric and Gerota's fascia thickening, pseudocyst in lesser sac, abscess (gas or thick-walled fluid collection), pancreatic necrosis (low attenuation gas-containing non-enhancing pancreatic tissue), hemorrhage
- Management: supportive therapy
  - CT-guided needle aspiration and/or drainage done for abscess when clinically indicated
  - Pseudocyst may be followed by CT and drained if symptomatic

**Chronic Pancreatitis**
- Pathogenesis: (see *Gastroenterology, G45*)
- Best imaging modality: MRCP (can show calcification and duct obstruction)
- Findings: U/S, CT scan, and MRI may show calcifications, ductal dilatation, enlargement of the pancreas and fluid collections (e.g. pseudocysts) adjacent to the gland
Genitourinary System and Adrenal

Angiography of Gastrointestinal Tract

- anatomy of the GI tract arterial blood supply branches
  - celiac artery: hepatic, splenic, gastroduodenal, left/right gastric
  - superior mesenteric artery: jejunal, ileal, ileo-colic, right colic, middle colic
  - inferior mesenteric artery: left colic, superior rectal
- imaging modalities
  - conventional angiogram: invasive (usual approach via femoral puncture), catheter used
    - flush aortography: catheter injection into abdominal aorta, followed by selective arteriography of individual vessels
  - CT angiogram: modality of choice, non-invasive using IV contrast (no catheterization required)

Genitourinary System and Adrenal

Urological Imaging

KUB (Kidney, Ureter, and Bladder X-ray)
- a frontal supine radiograph of the abdomen
- indication: useful in evaluation of radio-opaque renal stones (all stones but uric acid and indinavir) indwelling ureteric stents/catheters, and foreign bodies in abdomen
- findings: addition of IV contrast excreted by the kidney (intravenous urogram) allows greater visualization of the urinary tract, but has been largely replaced by CT urography

Abdominal CT

Renal Masses
- Bosniak classification for cystic renal masses
  - class I-II: benign and can be disregarded
  - class III: should be followed
  - class III-IV: suspicious for malignancy, requiring additional workup

Table 12. Bosniak Classification for Cystic Renal Masses

<table>

</tbody>
</table>

- plain CT KUB indications: general imaging of renal anatomy, renal colic symptoms, assessment of renal calculi (size and location), and hydronephrosis prior to urological treatment
- CT urography indications: investigation of cause of microscopic/gross hematuria, detailed assessment of urinary tracts (excretory phase), high sensitivity (95%) for uroepithelial malignancies of the upper urinary tracts, assessment of renal calculi
  - phases: unenhanced, excretory
  - renal triphasic CT indications: standard imaging for renal masses, allows accurate assessment of renal arteries and veins, better characterization of suspicious renal masses, especially in differentiating renal cell carcinoma from more benign masses, and pre-operative staging
  - phases: unenhanced, arterial and venous (nephrographic), excretory

Ultrasound
- indications: initial study for evaluation of kidney size and nature of renal masses (solid vs. cystic renal masses vs. complicated cysts); technique of choice for screening patients with suspected hydronephrosis (no IV contrast injection, no radiation to patient, and can be used in patients with renal failure); TRUS useful to evaluate prostate gland and guide biopsies; Doppler U/S to assess renal vasculature
- findings: solid renal masses are echogenic (bright on U/S), cystic renal masses have smooth well-defined walls with anechoic interior (dark on U/S), and complicated cysts have internal echoes within a thickened, irregular wall
Retrograde Pyelography
- **indications**: visualize the urinary collecting system via a cystoscope, ureteral catheterization, and retrograde injection of contrast medium, visualized by radiograph or fluoroscopy; ordered when the intrarenal collecting system and ureters cannot be opacified using intravenous techniques (patient with impaired renal function, high grade obstruction)
- **findings**: only yields information about the collecting systems (renal pelvis and associated structures), no information regarding the parenchyma of the kidney

Voiding Cystourethrogram
- bladder filled with contrast to the point where voiding is triggered
- fluoroscopy (continuous, real-time) to visualize bladder
- indications: children with recurrent UTIs, hydrenephrosis, hydroureret, suspected lower urinary tract obstruction or vesicoureteral reflux
- findings: contractility and evidence of vesicoureteric reflux

Retrograde Urethrogram
- a small Foley catheter placed into penile urethral opening
- indications: used mainly to study strictures or trauma to the male urethra; first-line study if trauma with blood present at urethral meatus

MRI
- **advantages**: high spatial and tissue resolution, lack of exposure to ionizing radiation and nephrotoxic contrast agents
- **indications**: indicated over CT for depiction of renal masses in patients with previous nephron sparing surgery, patients requiring serial follow-up (less radiation dosage), patients with reduced renal function, patients with solitary kidneys, clinical staging of prostate cancer (endorectal coil MRI)

Gynecological Imaging

Ultrasound
- transabdominal and transvaginal are the primary modalities, and are indicated for different scenarios
- transabdominal requires a full bladder to push out air-containing loops of bowel
  - indications: good initial investigation for suspected pelvic pathology
- TVUS provides enhanced detail of deeper/smaller structures by allowing use of higher frequency sound waves at reduced distances
  - indications: improved assessment of ovaries, first trimester development, and ectopic pregnancies

Hysterosalpingogram
- performed by x-ray images of the pelvis after cannulation of the cervix and subsequent injection of opacifying agent
- **indications**: useful for assessing pathology of the uterine cavity and fallopian tubes, evaluating uterine abnormalities (e.g. bicornuate uterus), or evaluation of fertility (absence of flow from tubes to peritoneal cavity indicates obstruction)

CT/MRI
- **indications**: evaluating pelvic structures, especially those adjacent to the adnexa and uterus
  - invaluable for staging gynecological malignancies and detecting recurrence

Sonohysterogram
- saline infusion sonohysterogram involves injecting fluid into the uterine cavity transcervically to provide enhanced endometrial visualization during TVUS examination
- indications: abnormal uterine bleeding, uterine cavity abnormalities that are suspected or noted on TVUS (e.g. leiomyomas, polyps, synchieae), congenital abnormalities of the uterine cavity, infertility, recurrent pregnancy loss
- contraindications: pregnancy, pelvic infection

Modality Based on Neuropathology

- Cognitive decline = CT
- Cord compression = MRI
- Decreased level of consciousness = CT
- Fish bone/other swallowed foreign body = CT
- Low back pain, radiculopathy = MRI
- Multiple sclerosis = MRI
- Neck infection = CT
- Orbital infection = CT
- Rule out bleed = CT
- Rule out aneurysm = CTA, MRA
- Seizure = CT
- Sinusitis = CT
- Stroke = CT, MRI
- Trauma = CT
- Weakness, systemically unwell = CT

Adrenal Mass

- Imaging modality: most often identified on CT scan as ‘incidentaloma,’ can also use CT/MRI to distinguish benign from malignant masses

Neuroradiology

Modalities

- CT is the modality of choice for most neuropathology; even under circumstances where MRI is preferred, CT is frequently the initial study performed because of its speed, availability, and lower cost
- Acute head trauma: CT is best for visualizing “bone and blood”; MRI is used only when CT fails to detect an abnormality despite strong clinical suspicion
- Acute stroke: MRI ideal, CT most frequently used
- Suspected subarachnoid or intracranial hemorrhage
- Meningitis: rule out mass effect (e.g. cerebral herniation, shift) prior to lumbar puncture
- Tinnitus and vertigo: CT and MRI are used in combination to detect bony abnormalities and CN VIII tumors, respectively

Skull Films

- Rarely performed, generally not indicated for non-penetrating head trauma
- Indications: screening for destructive bony lesions (e.g. metastases), metabolic disease, skull anomalies, post-operative changes and confirmation of hardware placement, skeletal surveys, multiple myeloma

CT

- Indications: excellent study for evaluation of bony and intracranial abnormalities
- Often done first and then with IV contrast to show vascular structures or anomalies
- Vascular structures and areas of blood-brain barrier impairment are opaque (e.g. hyperattenuating or white/show enhancement) with contrast injection
- When in doubt, look for Circle of Willis or confluence of sinuses to determine presence of contrast enhancement
• posterior fossa can be obscured by extensive bony-related streak artifact
• rule out skull fracture, epidural hematoma (lenticular shape), subdural hematoma (crescentic shape), subarachnoid hemorrhage, space occupying lesion, hydrocephalus, and cerebral edema
• multiplanar imaging can be performed with newer generation of multidetector CT scanners

Myelography
• introduction of water-soluble, low-osmotic contrast media into subarachnoid space using lumbar puncture followed by x-ray or CT scan
• indications: excellent study for disc herniations, traumatic nerve root avulsions, patients with contraindication to MRI

MRI
• indications: shows brain and spinal soft tissue anatomy in fine detail, clearly distinguishes white from grey matter (especially T1-weighted series), multiplanar reconstruction helpful in pre-operative assessment

Cerebral Angiography/CT Angiography/MR Angiography
• indications: evaluation of vascular lesions such as atherosclerotic disease, aneurysms, vascular malformations, arterial dissection
• conventional digital subtraction angiography remains the gold standard for the assessment of neck and intracranial vessels; however, it is an invasive procedure requiring arterial (femoral) puncture; catheter manipulation has risk of vessel injury (e.g. dissection, occlusion, vasospasm, emboli)
• MRA methods (phase contrast, time of flight, gadolinium-enhanced) and CTA are much less invasive without actual risk to intracranial or neck vessels
• MRA and CTA are often used first as ‘screening tests’ for the assessment of subarachnoid hemorrhage, vasospasm, aneurysms

Table 16. Two Types of Hydrocephalus

<tr>
<td>Non-Communicating</td>
<td>Obstruction within the ventricular system (e.g. mass obstructing the aqueduct or foramen of Monro); imaging shows dilatation of ventricles proximal to the obstruction</td>
</tr>
</tbody>
</table>

Nuclear Medicine
• SPECT using 99mTc-exametazime (HMPAO) and 99mTc-bisicat (ECD) imaging assesses cerebral blood flow by diffusing rapidly across the blood brain barrier and becoming trapped within neurons proportional to cerebral blood flow
• 18FDG PET imaging assesses cerebral metabolic activity
• indications: differentiation of residual tumour vs. radiation necrosis; localizing of epileptic seizure foci; evaluation of atypical dementia

Approach to CT Head
• think anatomically, work from superficial to deep
• scan: confirm that the imaging is of the correct patient, whether contrast was used, if the patient is aligned properly, if there is artifact present
• skin/soft tissue: examine the soft tissue superficial to the skull, looking for thickening suggestive of hematoma or edema; also evaluate the ear, orbital contents (globe, fat, muscles), parotid gland, muscles of mastication (masseter, temporalis, pterygoids), visualize pharynx
• bone and airspace (use the bone window): check calvarium, visualize mandible, visualize C-spine (usually C1 and maybe part of C2) for fractures, absent bone, lytic/sclerotic lesions; inspect sinuses and mastoid air cells for opacity that may suggest fluid, pus, blood, tumour, or fracture; status of the orbital floor in cases of facial trauma (coronal series best)
Multiple Sclerosis (see Neurology, N52)
- best imaging modality: MRI has high sensitivity in diagnosing MS (>90%) but low specificity (71-74%)
- findings
  - characteristic lesion on MRI is cerebral or spinal plaque
  - plaques typically found in periventricular region, corpus callosum (arranged at right angles to the corpus callosum) centrum semiovale, and to a lesser extent in deep white matter structures and basal ganglia
  - “Dawson’s fingers” refers to perivenular regions of demyelination that are seen to radiate outwards into the deep periventricular region
  - plaques usually have ovoid appearance, hyperintense on T2 and hypointense on T1
  - conventional T2 may underestimate plaque size and overall plaque burden – advanced techniques (diffusion tensor imaging and MR spectroscopy) can be used

Selected Pathology
- see Neurosurgery, NS20 for intracranial mass lesions
- see Neurosurgery, NS29 and Plastic Surgery, PL29 for head trauma
- see Emergency Medicine, ER7 for vertebral trauma
- see Neurosurgery, NS27 and Orthopedics, OR22 for degenerative spinal abnormalities

Cerebrovascular Disease (see Neurology, N6 and Neurosurgery, NS17)
- pathogenesis of stroke: see Neurology, N48
- best imaging modality: infarcts best detected by MRI > CT

Table 17. Temporal Findings of Infarction with CT and MRI

</table>

- carotid artery disease
  - best imaging modality: Duplex Doppler U/S
  - other modalities: MRA or CTA if carotid angioplasty or endarterectomy is under consideration (conventional angiography reserved for inadequate MRA or CTA)

Multiple Sclerosis (see Neurology, N52)
- best imaging modality: MRI has high sensitivity in diagnosing MS (>90%) but low specificity (71-74%)
- findings
  - characteristic lesion on MRI is cerebral or spinal plaque
  - plaques typically found in periventricular region, corpus callosum (arranged at right angles to the corpus callosum) centrum semiovale, and to a lesser extent in deep white matter structures and basal ganglia
  - “Dawson’s fingers” refers to perivenular regions of demyelination that are seen to radiate outwards into the deep periventricular region
  - plaques usually have ovoid appearance, hyperintense on T2 and hypointense on T1
  - conventional T2 may underestimate plaque size and overall plaque burden – advanced techniques (diffusion tensor imaging and MR spectroscopy) can be of use
Musculoskeletal System

Modalities

- see Imaging Modalities, MI2 for advantages and disadvantages of the following

Plain Film/X-Ray
- usually initial study used in evaluation of bone and joint disorders
- indications: fractures and dislocations, arthritis, assessment of malalignment, orthopedic hardware, and bone tumours (initial)
- minimum of two films orthogonal to each other (usually AP and lateral) to rule out a fracture
- image proximal and distal joints, particularly important with paired bones (e.g. radius/ulna)
- minimally effective in evaluating soft tissue injury

CT
- evaluation of fine bony detail
- indications: assessment of complex, comminuted, intra-articular, or occult fractures including distal radius, scaphoid, skull, spine, acetabulum, calcaneus, and sacrum
- evaluation of soft tissue calcification/ossification

MRI
- indications: evaluation of internal derangement of joints (e.g. ligaments, joint capsule, menisci, labrum, cartilage), assessment of tendons and muscle injuries, characterization and staging of soft tissue and bony masses

CNS Infections

- leptomeningitis
  - pathogenesis: inflammation of the pia or arachnoid mater, most often secondary to hematogenous spread from infection or via organisms gaining access across areas not protected by the blood-brain barrier (choroid plexus or circumventricular organs)
  - pathogens include: S. pneumoniae, H. influenzae, N. meningitidis, L. monocytogenes
  - best imaging modality: MRI (T2-weighted/FLAIR) superior to CT
  - findings:
    - meningeal enhancement (following the gyri/sulci and/or basal cisterns), hydrocephalus (communicating), cerebral swelling, subdural effusion
    - a normal MRI does not rule out leptomeningitis

- herpes simplex encephalitis (see Infectious Diseases, ID19)
  - pathogenesis: inflammation of the brain parenchyma secondary to infection with herpes simplex virus, asymmetrically affects the limbic regions of the brain (i.e. temporal lobes, orbitofrontal region, insula, and cingulate gyrus)
  - best imaging modality: MRI (T1- and T2 weighted)
  - findings:
    - acute (within 4-5 d): asymmetric high intensity lesions on T2 MRI in temporal and inferior frontal lobes strongly suggestive
    - DDx: infarct, tumour, status epilepticus, limbic encephalitis
    - CT may show low density in temporal lobe and insula; rarely basal ganglia involvement
    - long-term may show parenchymal loss to affected areas

- cerebritis/cerebral abscess
  - pathogenesis: an infection of the brain parenchyma (cerebritis) which can progress to a collection of pus (abscess), most frequently due to hematogenous spread of infectious organisms, commonly located in the distribution of the MCA
  - pathogens include: S. aureus (often in IV drug users, nosocomial), Streptococcus, Gram negative bacteria, Bacteroides
  - best imaging modality: MRI including DWI imaging series (abscess will be DWI positive); CT still used as a viable alternative
  - findings according to one of four stages of abscess formation
    - early cerebritis (1-3 d): inflammatory infiltrate with necrotic centre, low intensity on T1, high intensity on T2
    - late cerebritis (4-9 d): ring enhancement may be present
    - early capsule (10-13 d): ring enhancement
    - late capsule (14 d or greater): well demarcated ring-enhancing lesion, low intensity core, with mass effect; considerable edema around the lesion, seen as hyperintensity on T2

Figure 35. T2-weighted FLAIR: (A) sagittal (B) axial images of multiple sclerosis with periventricular “Dawson’s Fingers”

Figure 36. T2-weighted (FLAIR) coronal image of herpes simplex virus encephalitis affecting temporal lobes
Ultrasound
- indications: tendon injury (e.g. rotator cuff, Achilles tendon), detection of soft tissue masses and to determine whether cystic or solid, detection of foreign bodies, U/S-guided biopsy and injections
- Doppler determines vascularity of structures

Nuclear Medicine (Bone Scintigraphy)
- determine the location and extent of bony lesions
  - ⁹⁹mTc-methylene diphosphonate localizes to areas of increased bone turnover or calcification – growth plate in children, tumours, infections, fractures, metabolic bone disease (e.g. Paget’s), sites of reactive bone formation, and periostitis
- advantages: very sensitive, capable of imaging entire body with relatively low dose radiation
- disadvantages: low specificity, not widely available due to special requirements (e.g. gamma camera, radiopharmaceuticals)

Approach to Bone X-Rays
- identification: name, MRN, age of patient, type of study, region of investigation
- soft tissues: swelling, calcification/ossification
- joints: alignment, joint space, presence of effusion, osteophytes, erosions, bone density, overall pattern, and symmetry of affected joint
- bone: periosteum, cortex, medulla, trabeculae, density articular surfaces, bone destruction, bone production, appearance of the edges or borders of any lesions

Trauma

Fracture/Dislocation
- description of fractures
- site of fracture (bone, region of bone, intra-articular vs. extra-articular)
- pattern of fracture line (simple vs. comminuted)
- displacement (distal fragment with reference to the proximal fragment)
- soft tissue involvement (calcification, gas, foreign bodies)
- type of fracture (stress vs. pathologic)
- for specific fracture descriptions and characteristics of fractures, see Orthopedics, OR4

Arthritis

Radiographic Hallmarks of Osteoarthritis
- joint space narrowing – typically non-uniform
- subchondral sclerosis
- subchondral cyst formation
- osteophytes

Radiographic Hallmarks of Rheumatoid Arthritis
- joint space narrowing – typically uniform
- soft tissue swelling
- erosions
- periarticular osteopenia

Bone Tumour

Approach
- metastatic tumours to bone are much more common than primary bone tumours, particularly if age >40 yr
  - diagnosis usually requires a biopsy if primary not located
  - few benign tumours/lesions have potential for malignant transformation
  - MRI is good for tissue delineation and pre-operative assessment of surrounding soft tissues, neurovascular structures, and medullary/marrow involvement
  - plain film is less sensitive than other modalities but useful for assessing aggressiveness and constructing differential diagnosis

Considerations and Tumour Characteristics
- for specific bone tumours, see Orthopedics, OR45
- age: most common tumours by age group
  - <1 yr of age: metastatic neuroblastoma
  - 1-20 yr of age: Ewing’s sarcoma in tubular bones
  - 10-30 yr of age: osteosarcoma and Ewing’s tumour in flat bones
  - >40 yr of age: metastases, multiple myeloma, and chondrosarcoma
- multiplicity: metastases, myeloma, lymphoma, fibrous dysplasia, enchondromatosis
- location within bone
  - epiphysis: giant cell tumour, chondroblastoma, geode, eosinophilic granuloma, infection
  - metaphysis: simple bone cyst, aneurysmal bone cyst, enchondroma, chondromyxoid fibroma, nonossifying fibroma, osteosarcoma, chondrosarcoma
  - diaphysis: fibrous dysplasia, aneurysmal bone cyst, brown tumours, eosinophilic granuloma, Ewing’s sarcoma

Figure 37. X-ray of first carpometacarpal joint: normal image (left) and osteoarthritis (right) with joint space narrowing and subchondral sclerosis

Figure 38. Rheumatoid arthritis (A) compared with osteoarthritis (B) changes on X-ray
• expansile
  - aneurysmal bone cyst, giant cell tumour, enchondromas, brown tumours, metastases (especially renal and thyroid), plasmacytoma
• matrix mineralization
  - chondroid (popcorn calcification) or osseous
• margin/zone of transition: area between lesion and normal bone
• cortex: intact, disturbed
• periosteal reaction: onion-skinning, sunburst, Codman’s triangle, periosteal neocortex
• soft tissue mass

![Figure 39. Radiographic appearance of bone remodelling and destruction processes](image)

</tbody>
</table>

**Metastatic Bone Tumours**

- all malignancies have potential to metastasize to bone
- metastases are 20-30x more common than primary bone tumours
- metastasis can cause a lytic or a sclerotic reaction when seeding to bone
- when a primary malignancy is first detected, a bone scan is often part of the initial workup
- may present with pathological fractures or pain
- biopsy or determination of primary is the only way to confirm the diagnosis
- most common metastatic bone tumours: breast, prostate, lung, see Orthopedics, OR45

**Table 19. Characteristic Bone Metastases of Common Cancers**

**Infection**

**Osteomyelitis**

- MRI is the imaging modality of choice for demonstrating bone, bone marrow, and soft tissue abnormalities
- $^{99m}$Tc, followed by $^{111}$In-labeled white cell scan or gallium radioisotope scan
- plain film changes visible 8-10 d after process has begun
  - soft tissue swelling
  - local periosteal reaction
  - pockets of air (from anaerobes) may be seen in the tissues, may also suggest necrotizing fasciitis
  - mottled and nonhomogeneous with a classic “moth-eaten” appearance
  - cortical destruction

**Benign Lesions which may have Aggressive Features**

- Osteomyelitis
- Osteoblastoma
- Aneurysmal bone cyst
- Langerhans cell histiocytosis
- Myositis ossificans

**Periosteal Reaction**

- “Onion skinning” = Ewing’s sarcoma
- “Sunburst”, “hair on end” = osteosarcoma
- “Codman’s triangle” = osteosarcoma, Ewing’s sarcoma, subperiosteal abscess
Bone Abscess
- overlying cortex has periosteal new bone formation
- sharply outlined radiolucent area with variable thickness in zone of transition
- variable thickness periosteal sclerosis
- sequestrum: a piece of dead bone within a Brodie's abscess
- a sinus tract or cloaca may communicate between the abscess through the cortex to the surface of the bone
- best modality: MRI for bone, bone marrow, and soft tissue abnormalities; CT for sequestra and cortical erosions

Metabolic Bone Disease

Osteoporosis
- reduction in amount of normal bone mass; fewer and thinner trabeculae; diffuse process affecting all bones
- DEXA: gold standard for measuring bone mineral density
  - T-score: the number of standard deviations from the young adult mean, most clinically valuable
    - osteopenia: $-2.5 < \text{T-score} < -1$
    - osteoporosis: $\text{T-score} \leq -2.5$
  - Z-score: the number of standard deviations from the age-matched mean
  - risk of fracture: related to bone mineral density, age, history of previous fractures, steroid therapy
  - diagnostic sensitivity of DEXA highest when bone mineral density measured at lumbar spine and proximal femur
- appearance on plain film
  - osteopenia: reduced bone density on plain films
  - may also be seen with osteomalacia, hyperparathyroidism, and disuse
  - compression of vertebral bodies
  - biconcave vertebral bodies ("codfish" vertebrae)
  - long bones have appearance of thinned cortex and increased medullary cavity
  - look for complications of osteoporosis (e.g. insufficiency fractures: hip, vertebrae, sacrum, pubic rami)
- see Endocrinology, E40

Osteomalacia/Rickets
- reduction in bone mineral density; normal amount of bone but reduced mineralization of normal osteoid
- usually due to vitamin D deficiency, resulting in softening and bowing of long bones
- similar to osteoporosis, initial radiological appearance of osteopenia (coarse and poorly defined bone texture)
  "fuzzy", ill-defined trabeculae
- Looser’s zones (pseudofracture)
  - characteristic radiologic feature
  - fissures or clefts at right angles to long bones and extending through cortex
  - DDx: chronic renal disease, fibrous dysplasia, hyperparathyroidism, Paget’s, osteodystrophy, X-linked hypophosphatemia

Figure 40. Osteomalacia, osteopenia, and osteoporosis
**Hyperparathyroidism**
- most common cause is renal failure (secondary hyperparathyroidism)
- chondrocalcinosis
- calcium crystal deposition in hyaline cartilage or fibrocartilage (including arteries and peri-articular soft tissue)
- resorption of bone typically in hands (subperiosteal and at tufts), sacroiliac joints (subchondral), skull (“salt and pepper” appearance), osteoclastoma (brown tumours)
- "rugger jersey spine": band-like osteosclerosis at superior/inferior margins of vertebral bodies

**Paget’s Disease**
- abnormal remodelling involving single or multiple bones – especially skull, spine, pelvis
- 3 phases: 1st phase = lytic, 2nd phase = mixed (lytic/sclerotic), 3rd phase = sclerotic
- features
  - coarsening of the trabeculae with bone expansion
  - bone softening/bowing
  - bone scan will reveal high activity, especially at bone ends
  - thickened cortex
- see Endocrinology, E44

**Nuclear Medicine**

**Brain**
- 99mTc-exametazime (HMPAO) and 99mTc-bicsate (ECD) imaging used in SPECT to assess cerebral blood flow and cellular metabolism, taken up predominantly in grey matter
  - used for dementia, traumatic brain injury, and to a lesser extent vasculitis, neuropsychiatric disorders, and occasionally stroke
  - most commonly used tracers to confirm brain death (i.e. absent blood flow to the brain and absent uptake on delayed planar and SPECT images in brain and brainstem, assuming study is technically adequate)
  - either tracer can be used for seizure imaging to assess for the most likely location of epileptogenic focus but usually must be made available for 24 h and the patient followed by a nurse who is competent to administer the activity at the time of seizure
- PET imaging assesses metabolic activity most commonly with 18FDG; used for dementia imaging, grade and stage of brain tumours, occasionally for seizure disorder imaging, and vasculitis; PET imaging with amyloid tracers for diagnosis of Alzheimer’s disease is becoming more common
- CSF imaging, intrathecal administration of 111In DTPA to evaluate CSF leak or to differentiate normal pressure hydrocephalus from brain atrophy
- CSF shunt evaluation for obstruction (most commonly ventriculoperitoneal) with sterile or pyrogen free 99mTc (usually) or 111In-DTPA; small quantity of activity is injected into the reservoir under sterile conditions and should flow freely into the peritoneal cavity by 45 min; maneuvers such as pumping the shunt, sitting the patient upright or ambulating are acceptable to encourage flow during this time
- adrenergic imaging of the heart with MIBG has been used to differentiate dementias with autonomic dysfunction (i.e. Lewy Body and Parkinson’s disease) from other forms of dementia (i.e. autonomic impairment associated with decreased MIBG activity in the heart)

**Thyroid**

**Radioactive Iodine Uptake** (see Endocrinology, E21)
- index of thyroid function (trapping and organification of iodine)
- radioactive 131I given PO to fasting patient (small quantity)
- measure percentage of administered iodine taken up by thyroid
- increased RAU: toxic multinodular goitre, toxic adenoma, Graves’ disease
- decreased RAU: subacute thyroiditis, late Hashimoto’s disease, exogenous thyroid hormone or iodine, falsely decreased in patient with recent radiographic contrast studies, high dietary iodine (e.g. seaweed, taking a “thyroid vitamin”)
- important – iodine uptake helps in the differential of hyperthyroidism only, not hypothyroidism (exception is pediatrics)

**Thyroid Imaging (Scintiscan)**
- 99mTc-pertechnetate IV or radioactive iodine (123I); most Canadian sites use pertechnetate to reduce cost
- provides functional anatomic detail
- hot (hyperfunctioning) lesions: usually benign (e.g. adenoma, toxic multinodular goitre), cancer very unlikely (less than 1%)
- cold (hypofunctioning) lesions: cancer must be considered until biopsy negative even though only 6-10% are cancerous; decision to biopsy should be based on clinical and sonographic features
- isointense i.e. “warm” lesions: cancer must be considered as an isointense lesion may represent cold nodules superimposed on normal tissue; if cyst suspected, correlate with U/S

---

Figure 41. Multinodular goitre (top). Cold nodule (bottom)
Radioiodine Ablation
- $^{131}$I for Graves' disease, multinodular goitre, thyroid cancer (in the case of thyroid cancer, ablation performed at higher dose and after thyroidectomy)
- serum thyroglobulin used to detect recurrent thyroid cancer in a patient that has received ablation
- advice should be given for patient-specific precautions to remain away from family members and caregivers to reduce radiation exposure after thyroid ablation, do not initiate pregnancy for 6 mo, small risk of exophthalmos, thyroid storm, secondary malignancy

Pediatric Hypothyroidism
- pertechnetate thyroid scan can differentiate thyroid agenesis, hemiagenesis, lingular thyroid, organization defect, however should not wait for a diagnosis to start thyroid hormone replacement in a neonate; start immediately

Respiratory
V/Q Scan
examine areas of lung in which ventilation and perfusion do not match
- ventilation scan
  - patient breathes radioactive gas (nebulized $^{99m}$Tc-DTPA, $^{133}$Xe, or most commonly Technegas) through a closed system, filling alveoli proportionally to ventilation
  - ventilation scan defects indicate: airway obstruction (i.e. air trapping), chronic lung disease, bronchospasm, tumour mass obstruction
- perfusion scan
  - radiotracer injected IV ($^{99m}$Tc-MAA) → trapped in pulmonary capillaries (0.1% of arterioles occluded) according to blood flow
  - relatively contraindicated in severe pulmonary HTN, right-to-left shunt, previous history of pneumonectomy, small child. In these cases fewer particles are usually given
- to rule out PE
  - indications: some institutions favour in pregnancy (lower radiation dose to breast than CT), or where CT contrast contraindicated (e.g. contrast allergy, renal failure)
  - areas of lung that are well-ventilated but not perfused (unmatched defect) are suspicious for acute infarction
  - defects are wedge-shaped, extend to periphery, usually bilateral and multiple
  - often reported as high probability (> 2 large i.e. segmental mismatched perfusion defects), intermediate, low, very low, or normal according to modified PIOPED II criteria although now are increasingly reported as PE present, indeterminate or normal
  - useful in finding clinically important emboli
  - decreased detection of incidentalomas commonly found on CT
- not valid for assessment of PE when patients have consolidation and the test can be limited by ventilatory problems (e.g. COPD), much like CT
- modified V/Q scan (perfusion only, lower dose contrast) may be used for pregnant patients if CXR is normal or if there are ventilatory problems

Myocardial Perfusion Scanning
- to investigate coronary artery disease (CAD), assess treatment of CAD pre-op risk stratification, viability testing
- $^{99m}$Tc-sestamibi, or $^{99m}$Tc-tetrofosmin are used most commonly; thallium 201 was used previously but largely discontinued due to high radiation doses to patients and unfavourable imaging characteristics; today thallium still used for viability studies
- injected at peak exercise (85% max predicted heart rate by the Bruce protocol, chest pain, ECG changes) or after persantine challenge (vasodilator), or after dobutamine infusion (chronotropic, again to 85% predicted heart rate); can be done as stress only protocol with optional rest or as stress and rest combined protocol (i.e. as 1 day or 2 day protocol)
- patients with left bundle usually given pharmacologic stress because ECG is difficult to interpret for ST changes and avoids a characteristic artifact
- pharmacologic stress contraindicated if sBP is <90; persantine exacerbates asthma, so patients with asthma and wheeze who cannot exercise usually get dobutamine infusion; reverse persantine with aminophylline or caffeine
- persistent defect (at rest and stress) suggests infarction or myocardial scar; reversible defect (only during stress) suggests ischemia
- used to discriminate between reversible (ischemia) vs. irreversible (infarction) changes when other investigations are equivocal
- Courage trial indicates that patients with >10% ischemic myocardium benefit most from revascularization
- see Cardiology and Cardiac Surgery C13
Radionuclide Ventriculography
• $^{99m}$Tc-tagged to red blood cells, tagged albumin is also acceptable
• first pass through RV $\rightarrow$ pulmonary circulation $\rightarrow$ LV; provides information about RV function, presence of shunts
• cardiac MUGA scan sums multiple cardiac cycles, usually at least 200 beats
• evaluation of LV function and regional wall motion, ejection fraction
• images are obtained by gating (synchronizing) the count acquisitions to the ECG signal
• can assess diastolic dysfunction
• provides information on ejection fraction (normal = 50-65%), ventricular volume, and wall motion
• indications: most commonly to monitor potential cardiac toxicity with chemotherapy or herceptin, as a gold standard of ejection fraction in defibrillator workup

Abdomen and Genitourinary System

HIDA Scan (Cholescintigraphy)
• IV injection of $^{99m}$Tc-disofenin (DISIDA) or $^{99m}$Tc-mebrofenin which is bound to protein, taken up, and excreted by hepatocytes into biliary system
• can be performed in non-fasting state but prefer NPO after midnight
• indicated in workup of cholecystitis when abdominal ultrasound result is equivocal:
  • acute cholecystitis: no visualization of gallbladder at 4 h or 1 h after administration of morphine
  • chronic cholecystitis: no visualization of gallbladder at 1 h but seen at 4 h or after morphine administration
• gallbladder visualized when cystic duct is patent (rules out acute cholecystitis with >99% certainty), usually seen by 30 min-1 h
• differential diagnosis of obstructed cystic duct: acute/chronic cholecystitis, decreased hepatobiliary function (commonly due to alcoholism), bile duct obstruction, parenteral nutrition, fasting less than 4 h or more than 24 h
• also used to assess bile leaks post-operatively or in trauma
• gallbladder ejection fraction (>38% is normal) can be measured after a fatty meal or CCK to assess for biliary dyskinesia

RBC Scan
• IV injection of radiotracer with sequential images of the abdomen ($^{99m}$Tc RBCs)
• GI bleed
  • if bleeding acutely at <0.5 mL/min, the focus of activity in the images generally indicates the site of the acute bleed, look for a change in shape and location on sequential image, requires active bleeding to localize
  • if bleeding acutely at >0.5 mL/min, use angiography (more specific)
• liver lesion evaluation
  • hemangioma has characteristic appearance: cold early (limited blood flow to lesion), fills later (accumulation of tagged cells greater than surrounding liver parenchyma)

Other Important Nuclear Medicine Abdominal Tests
• Meckel's Scan: uses $^{99m}$m pertechnetate; give patient ranitidine premedication; Meckel's diverticulum contains gastric mucosa which will light up at the same time as the stomach and get brighter with time like stomach
• $^{111}$In octreoscan: a somatostatin analog used for evaluation and staging of neuroendocrine tumours including carcinoid; gastrinoma and carcinoid tend to be more octreotide avid than insulinoma.
• iodinated MIBG: a norepinephrine analogue, used for pheochromocytoma, neuroblastoma and medullary thyroid cancer most commonly; limited cardiac applications as above
• solid and liquid gastric emptying: a standardized solid or liquid meal is labelled, usually with $^{99m}$Tc sulfur colloid and gastric emptying studied over time. There are normal ranges for solids and liquids

Urea Breath Test
• indication: diagnosis of gastric Helicobacter pylori infection
• patient administered 14C-labelled urea orally, urea metabolized by H. pylori to ammonia and $^{14}$CO$_2$, $^{14}$C-labelled CO$_2$ is measured via plastic filament detectors or liquid scintillation

Functional Renal Imaging
• evaluation of renal function and anatomy using $^{99m}$Tc DTPA or $^{99m}$Tc MAG3
• frequently used to provide index of relative function between two kidneys
• frequently used in adults to assess for UPJ obstruction (by assessing the clearance half time with lasix), and assess renal transplants or as a nuclear GFR study in patients wanting to donate kidneys
• in children, imaging with $^{99m}$Tc DMSA is used to assess for pyelonephritis
• in children, the injection of tracer into the bladder via foley catheter is often used to assess for reflux
Bone Scan
- isotopes, usually 99mTc-diphosphonate
- radioactive tracer binds to hydroxyapatite of bone matrix
- increased binding when increased blood supply to bone and/or high bone turnover (active osteoblasts)
- indications: bone pain of unknown origin, staging or restaging of cancer with bone mets (or primary bone cancer), imaging of arthroplasty complications like loosening or infection, osteomyelitis imaging
- when used to assess for osteomyelitis, usually done in combination with gallium or white blood cell scan
- differential diagnosis of positive bone scan: bone metastases (breast, prostate, lung, thyroid), primary bone tumour, arthritis, fracture, infection, anemia, Paget's disease
- lytic lesions like multiple myeloma, renal cell cancer, eosinophilic granuloma: typically normal or cold (false negative); need a skeletal survey
- "superscan": increased bone uptake and poor renal uptake due to diffuse metastases (breast, prostate) or metabolic causes (e.g. renal osteodystrophy)

Interventional Radiology

Vascular Procedures

Angiography
- injection of contrast material through a catheter placed directly into an artery or vein to delineate vascular anatomy
- catheter can be placed into a large vessel (e.g. aorta, vena cava) for a "flush" or selectively placed into a branch vessel for more detailed examination of smaller vessels and specific organs
- indications: diagnosis of primary occlusive or stenotic vascular disease, aneurysms, coronary, carotid and cerebral vascular disease, PE, trauma, bleeding (GI, hemoptysis, hematuria), vascular malformations, as part of endovascular procedures (endovascular aneurysm repair, thrombolysis, stenting, and angioplasties)
- complications (<5% of patients): puncture site hematoma, infection, pseudoaneurysm, AV fistula, dissection, thrombosis, embolic occlusion of a distal vessel
- due to improved technology, non-invasive evaluation of vascular structures is being performed more frequently (colour Doppler U/S, CTA, and MRA)
- see Neuroradiology, MI18

Percutaneous Transluminal Angioplasty and Stents
- introduction and inflation of a balloon into a stenosed or occluded vessel to restore distal blood supply
- common alternative to surgical bypass grafting with 5yr patency rates similar to surgery, depending on site
- renal, iliac, femoral, mesenteric, subclavian, coronary, and carotid artery stenoses are amenable to treatment
- vascular stents may help improve long-term results by keeping the vessel wall patent after angioplasty; also used for angioplasty failure or complications
- stent grafts (metal mesh covered with durable fabric) may provide an alternative treatment option for AV fistulas
- complications: similar to angiography, but also includes vessel rupture

Thrombolytic Therapy
- may be systemic (IV) or catheter directed
- infusion of a fibrinolytic agent (urokinase, streptokinase, TNK, tPA – used most commonly) via a catheter inserted directly into a thrombus
- can restore blood flow in a vessel obstructed with a thrombus or embolus
- indications: treatment of ischemic limb (most common indication), early treatment of MI or stroke to reduce organ damage, treatment of venous thromboembolism (DVT or PE)
- complications: bleeding, stroke, distal embolus, reperfusion injury with myoglobinuria and renal failure if advanced ischemia present

Embolization
- injection of occluding material into vessels
- permanent agents: amplatzer plugs, coils, glue, and onyx
- temporary: gel foam, autologous blood clots
- indications: management of hemorrhage (epistaxis, trauma, GI bleed, GU bleed), treatment of arteriovenous malformation, pre-operative treatment of vascular tumours (bone metastases, renal cell carcinoma), varicocele embolization for infertility, symptomatic uterine fibroids
- complications: post-embolization syndrome (pain, fever, leukocytosis), unintentional embolization of a non-target organ with resultant ischemia

Thrombolytic Therapy for Pulmonary Embolism

Purpose: To assess the effects of thrombolytic therapy in patients with acute pulmonary embolism (PE).

Methods: Systematic review of RCTs evaluating thrombolytic therapy followed by heparin versus heparin alone, heparin plus placebo or surgical intervention in patients with acute PE. Studies comparing two different thrombolytic agents or different doses of the same thrombolytic drug were not considered eligible. Main outcomes of interest were death, recurrence of PE, and major and minor hemorrhagic events.

Results: Eighteen trials with 2,197 participants were included. Thrombolytics plus heparin were associated with a reduction in odds of death relative to heparin alone or heparin plus OR 0.57, 95% CI 0.37 to 0.87, P = 0.02) and recurrence of PE (OR 0.53, 95% CI 0.39 to 0.78, P < 0.001). Length of hospital stay (mean difference (MD) 1.35, 9.27 to 1.58) and quality of life were similar between groups. Based on one study, stroke occurred more often in the thrombolytics group (OR 12.10, 1.57 to 93.39).

Conclusion: Low-quality evidence suggests thrombolytics reduce death following acute PE compared with heparin and may be helpful in reducing PE recurrence, but may cause more major and minor hemorrhagic events and stroke events.
Inferior Vena Cava Filter
- insertion of temporary or permanent metallic “umbrellas” to mechanically trap emboli and prevent PE
- inserted via femoral, jugular, or antecubital vein
- usually placed infrarenally to avoid renal vein thrombosis
- indications: contraindication to anticoagulation, failure of adequate anticoagulation (e.g. recurrent PE despite therapeutic anticoagulant levels), complication of anticoagulation

Central Venous Access
- variety of devices available
- PICC, external tunneled catheter (Hickman or dialysis catheters), subcutaneous port (Portacath™)
- indications: chemotherapy, TPN, long-term antibiotics, administration of fluids and blood products, blood sampling
- complications: venous thrombosis, central venous stenosis, infection including sepsis, and pneumothorax

Nonvascular Interventions

Percutaneous Biopsy
- replaces open surgical procedure
- many sites are amenable to biopsy using U/S, fluoroscopy, CT or MR guidance
- complications: false negative (sampling error or tissue necrosis), pneumothorax in 30% of lung biopsies (chest tube required in ~5%), acute pancreatitis (pancreatic biopsies), bleeding from liver biopsies in patients with uncorrectable coagulopathies or ascites (can be minimized with transjugular approach)

Abscess Drainage
- placement of a drainage catheter into an infected fluid collection
- administer broad spectrum IV antibiotics prior to procedure
- routes: percutaneous (most common), transgluteal, transvaginal, transrectal
- complications: hemorrhage, injury to intervening structures (e.g. bowel), bacteremia, sepsis

Percutaneous Biliary Drainage/Cholecystostomy
- placement of drainage catheter ± metallic stent into obstructed biliary system (PBD) or gallbladder (cholecystostomy) for relief of jaundice or infection
- percutaneous gallbladder access can be used to crush or remove stones
- indications
  - cholecystostomy: acute cholecystitis
  - PBD biliary obstruction secondary to stone or tumour, cholangitis
- complications
  - acute: sepsis, hemorrhage
  - long-term: tumour ingrowth and stent occlusion

Percutaneous Nephrostomy
- placement of catheter into renal collecting system
- indications: hydronephrosis, pyonephrosis, ureteric injury with or without urinary peritonitis (traumatic or iatrogenic)
- complications: bacteria and septic shock, hematuria due to pseudoaneurysm or AV fistulas, injury to adjacent organs

Gastrostomy/Gastrojejunostomy
- percutaneous placement of catheter directly into either stomach (gastrostomy) or through stomach into small bowel (transgastric jejunostomy)
- indications: inability to eat (most commonly CNS lesion, e.g. stroke), esophageal obstruction, or decompression in gastric outlet obstruction
- complications: gastroesophageal reflux with aspiration peritonitis, hemorrhage, bowel or solid organ injury

Radiofrequency Ablation
- U/S- or CT-guided probe is inserted into tumour, radiofrequency energy delivered through probe causes heat deposition and tissue destruction
- indications: hepatic tumours (HCC and metastases), renal tumours
- complications: destruction of neighbouring tissues and structures, bleeding
**Breast Imaging**

**Modalities**

**Mammography**

**Description**
- x-ray imaging of the breasts for screening in asymptomatic patients, or diagnosis of clinically-detected or screening-detected abnormalities (see General Surgery, GS56)
- routine evaluation involves two standard views: cranio-caudal and medial-lateral-oblique

**Indications**
- screening
  - begin screening from age 50 q2-3yr
  - no strong data to support screening >70 yr, but may continue screening if in good general health
  - if <50, screening is only recommended for those with high risk of breast cancer
  - screening detects 2-8 cancers/1,000 women screened
- surveillance
  - follow-up of women with previous breast cancer
- diagnostic: includes mammography with special views and/or ultrasound
  - workup of an abnormality that may be suggestive of breast cancer including a lump or thickening, localized nodularity, dimpling or contour deformity, a persistent focal area of pain, and spontaneous serous or sanguinous nipple discharge from a single duct
  - women with abnormal screening mammograms
  - suspected complications of breast implants

**Breast Ultrasound**

**Indications**
- characterization of palpable abnormalities
  - ultrasound is 1st line <30 yr and in lactating and pregnant women
  - >30 yr need mammogram first
- further characterization of mammographic findings
- guidance for interventional procedures

**Breast MRI**

**Description**
- contrast-enhanced MRI of the breasts
- sensitive for detecting invasive breast cancer (95-100%) but specificity variable (37-97%)
- for diagnosis, used only after mammography and U/S investigation
- use as a screening modality is limited to high-risk patients, in conjunction with mammography

**Indications**
- “problem-solving” of indeterminate findings following complete mammographic and ultrasound workup
- evaluation of patients with suspected silicone implant rupture and problems associated with breast implants
- evaluation of previously diagnosed breast cancer: positive margins, recurrence, response to chemotherapy
• high-risk screening
  • known BRCA1 or BRCA2 mutation, or other gene predisposing to breast cancer, or untested first-degree relative of a carrier of such a gene mutation
  • family history consistent with a hereditary breast cancer syndrome and/or estimated personal lifetime cancer risk >25%
  • high-risk marker on prior biopsy (atypical ductal hyperplasia, atypical lobular hyperplasia, lobular carcinoma in situ)
  • radiation therapy to chest (before age 30)

**Breast Intervventional Procedures**

**Description**
• includes fine needle aspirate biopsy, core needle biopsy, stereotactic biopsy, MRI guided biopsy, abscess drainage, and cyst aspiration (see General Surgery, GS59)

**Indications**
• cystic mass: complex cyst, symptomatic, suspected abscess
• solid mass: confirm diagnosis of a lesion suspicious for malignancy (BI-RADS® Category 4 or 5)
• suspicious calcifications: confirm diagnosis of a lesion suspicious for malignancy (BI-RADS® Category 4 or 5) – stereotactic biopsy
• initial percutaneous biopsy procedure that was insufficient or discordant with imaging
• presurgical wire localization of a lesion

**Breast Findings**

**Breast Masses**
• **definition:** a space-occupying lesion seen in two different projections; if seen in only a single projection it should be called an “asymmetry” until its three-dimensionality is confirmed

<table>
<thead>

<td><strong>Shape</strong></td>
</tr>
<tr>
<td>-----------</td>
</tr>
<tr>
<td>Margin</td>
</tr>
<tr>
<td>Density</td>
</tr>
<tr>
<td>Calcifications (± mass)</td>
</tr>
</tbody>
</table>

**Other Findings**
• tubular density/dilated duct: branching tubular structures usually represent enlarged ducts (milk ducts); if they are clearly identified as such, these densities are of little concern
• intramammary lymph node: typical lymph nodes are circumscribed, reniform and often have a fatty notch and centre; usually less than 1 cm, and usually seen in the outer, often upper part of the breast; when these characteristics (particularly fatty centre or notch) are well seen, the lesion is almost always benign and insignificant
• focal asymmetry: area of breast density with similar shape on two views, but completely lacking borders and conspicuity of a true mass; must be carefully evaluated with focal compression to exclude findings of a true mass or architectural distortion
• if focal compression shows mass-like character – or if the area can be palpated – biopsy generally recommended

Anatomy of the Kidney

- see Urology, U2

Renal Structure and Function

The Nephron
- basic structural and functional unit of the kidney, approximately 1 million per kidney
- 2 main components: glomerulus and attached renal tubule
- direction of blood flow: afferent arteriole → glomerular capillaries → efferent arteriole → vasa recta (the capillaries surrounding the tubules) → renal venules

</tbody>
</table>

The Glomerulus
- site where blood constituents are filtered through to the kidney tubules for excretion or reabsorption
- filtration occurs across the glomerular filtration barrier (endothelium, GBM, podocytes) into Bowman’s space
- particles are selectively filtered by size (<60 kDa) and charge (negative charge repelled)
• consists of following cell types:
  1. Mesangial cells
     • structural cells that support the vascular tree; they are also contractile and produce vasoactive substances to help control blood flow
  2. Capillary endothelial cells
     • one of the cells of the glomerular filtration barrier; help form the plasma filtration apparatus due to their sinusoidal nature and glycosylation; contribute to the production of the GBM
  3. Visceral epithelium (podocytes)
     • one of the cells of the glomerular filtration barrier; help form the plasma filtration apparatus due to their interdigitated foot process that form slit diaphragms; contribute to the production of the GBM
  4. Parietal epithelium
     • lines the interior of Bowman’s capsule and contains a podocyte progenitor population
  5. Juxtaglomerular cells
     • smooth muscle cells in lining of afferent arteriole; produce, store and secrete renin

The Renal Tubules
• reabsorption and secretion occur between the renal tubules and vasa recta forming urine for excretion
• each segment of the tubule selectively transports various solutes and water and is targeted by specific diuretics
Renal Hemodynamics

- **GFR**
  - is the sum of the filtration across all nephrons
  - the rate of fluid transfer between glomerular capillaries and Bowman's space
  - average 180 L/d, of which 99% is reabsorbed, giving a urine output of 1.0-1.5 L/d to match oral fluid intake
  - normal urine output is 0.5-2.0 ml/kg/h in adults
  - GFR is highest in early adulthood, and decreases thereafter starting around age 40

- **2 mechanisms of autoregulation**
  - myogenic mechanism: release of vasoactive factors such as prostaglandins in response to changes in perfusion pressure (e.g. → perfusion pressure → afferent arteriolar constriction → decreased GFR)
  - tubuloglomerular feedback: changes in Na+ delivery to macula densa lead to changes in afferent arteriolar tone (e.g. increased delivery causes afferent constriction)

- **FF**
  - percentage of RPF filtered across the glomeruli
  - expressed as a ratio: FF = GFR/RPF; normal = 0.2 or 20%
  - renin is released from juxtaglomerular apparatus in response to decreased RPF and maintain sodium balance
  - renin is an important enzyme in the renin angiotensin aldosterone system (RAAS), that converts angiotensinogen to angiotensin I

Glomerular Filtration Rate

\[
GFR = K_f (\Delta P - \Delta \Pi) 
\]

- \( K_f \) = ultrafiltration coefficient
- \( \Delta P \) = hydrostatic pressure difference between glomerular capillaries and Bowman’s space
- \( \Delta \Pi \) = osmotic pressure difference between glomerular capillaries and Bowman’s space
- \( \Delta P - \Delta \Pi = \text{net outward pressure} \)

Angiotensin II Effects:

1. Vasoconstriction
2. \( \uparrow \) vascular smooth muscle growth
3. \( \uparrow \) Na+ reabsorption
4. \( \uparrow \) aldosterone
5. \( \uparrow \) bicarbonate products
# Measurement of Renal Function

## Limitations of Using Serum Cr Measurements

1. **must be in steady state**
   - constant GFR and rate of production of Cr from muscle; however, serum Cr will not immediately reflect sudden reduction in GFR until new Cr steady-state is reached
2. **GFR must fall substantially before Cr rises above normal laboratory range**
   - with progressive renal failure, remaining nephrons compensate with hyperfiltration
   - GFR is relatively preserved despite significant structural damage
3. **plasma [Cr] is influenced by the rate of Cr production**
   - lower production with smaller muscle mass (e.g. female, elderly, low weight)
     - for example, consider plasma [Cr] of 100 µmol/L in both of these patients
       - 20 yr old man who weighs 100 kg, GFR = 144 mL/min
       - 80 yr old woman who weighs 50 kg, GFR = 30.6 mL/min
     - clinical correlation: GFR decreases with age but would not be reflected as a rise in serum Cr due to the age-associated decline in muscle mass
4. **tubular secretion of Cr increases as GFR decreases**
   - serum Cr and CrCl overestimate low GFR
   - certain drugs (cimetidine, trimethoprim) interfere with Cr secretion
5. **errors in Cr measurement**
   - very high bilirubin level causes [Cr] to be falsely low
   - acetooacete (a ketone body) and certain drugs (cefoxitin) create falsely high [Cr]

## Measurement of Urea Concentration

- urea is the major end-product of protein metabolism
- plasma urea concentration reflects renal function but should not be used alone as it is modified by a variety of other factors
- urea production reflects dietary intake of protein and catabolic rate; increased protein intake or catabolism (sepsis, trauma, GI bleed) causes urea level to rise
- ECF volume depletion causes a rise in urea independent of GFR or plasma [Cr]
- in addition to filtration, a significant amount of urea is reabsorbed along the tubule
- reabsorption is increased in hypernatreemic states
- typical ratio of urea to [Cr] in serum is 1:12 in SI units (using mmol/L for urea and µmol/L for Cr)
**Urinalysis**

- Use dipstick in freshly voided urine specimen to assess the following:

1. **Specific Gravity**
   - Ratio of the mass of equal volumes of urine/H₂O
   - Range is 1.001-1.030
   - Values <1.010 reflect dilute urine, values >1.020 reflect concentrated urine
   - Value usually 1.010 in ESRD (isosthenuria: same specific gravity as plasma)

2. **pH**
   - Urine pH is normally between 4.5-7.0; if persistently alkaline, consider
     - RTA
     - UTI with urease-producing bacteria (e.g. Proteus)

3. **Glucose**
   - Freely filtered at glomerulus and reabsorbed in proximal tubule
   - Causes of glucosuria include:
     1. Hyperglycemia >9-11 mmol/L leads to filtration that exceeds tubular resorption capacity
     2. Increased GFR (e.g. pregnancy)
     3. Proximal tubule dysfunction (e.g. Fanconi's syndrome)

4. **Protein**
   - Dipstick only detects albumin; other proteins (e.g. Bence-Jones, Ig, Tamm-Horsfall) may be missed
   - Microalbuminuria (morning ACR of 2.0 - 20 mg/mmol) is not detected by standard dipstick; greater than these ranges would be macroalbuminuria (see Diabetes, NP31)
   - Sulfosalicylic acid detects all protein in urine by precipitation
   - Gold standard: 24 h timed urine collection for total protein

5. **Leukocyte Esterase**
   - Enzyme found in WBC and detected by dipstick
   - Presence of WBCs indicates infection (e.g. UTI) or inflammation (e.g. AIN)

6. **Nitrites**
   - Nitrates in urine are converted by some bacteria to nitrites
   - High specificity but low sensitivity for UTI

7. **Ketones**
   - Positive in alcoholic/diabetic ketoacidosis, prolonged starvation, fasting

8. **Hemoglobin**
   - Positive in hemoglobinuria (hemolysis), myoglobinuria (rhabdomyolysis), and true hematuria (RBCs seen on microscopy)

### Urine Microscopy

<table>
<thead>

</tbody>
</table>

1. **CELLS**

   **Erythrocytes**
   - Hematuria = greater than normal range of 2-3 RBCs per HPF
   - Dysmorphic RBCs and/or RBC casts suggest glomerular bleeding (e.g. proliferative GN)
   - Isomorphic RBCs, no casts suggest extraglomerular bleeding (e.g. bladder Ca)

   **Leukocytes**
   - Pyuria = greater than upper limit of normal: 3 WBCs per HPF
   - Indicates inflammation or infection
   - If persistent sterile pyuria present (i.e. negative culture), consider: chronic urethritis, prostatitis, interstitial nephritis, calculi, papillary necrosis, renal TB, viral infections
**Eosinophils**
- detected using Wright's or Hansel's stain (not affected by urine pH)
- consider AIN, atheroembolic disease

**Oval Fat Bodies**
- renal tubular cells filled with lipid droplets
- seen in heavy proteinuria (e.g. nephrotic syndrome)

**2. CASTS**
- cylindrical structures formed by intratubular precipitation of Tamm-Horsfall mucoprotein; cells may be trapped within the matrix of protein

<table>
<thead>

</tbody>
</table>

**3. CRYSTALS**
- uric acid: consider acid urine, hyperuricosuria
- calcium phosphate: alkaline urine
- calcium oxalate: consider hyperoxaluria, ethylene glycol poisoning
- sulfur: sulfa-containing antibiotics

**Urine Biochemistry**
- commonly measure: Na⁺, K⁺, Cl⁻, osmolality, and pH
- no "normal" values; electrolyte excretion depends on intake and current physiological state
- results must be interpreted in the context of a patient's current state, for example:
  1. ECF volume depletion: expect low urine [Na⁺] (kidneys should be retaining Na⁺)
     - urine [Na⁺] >20 mmol/L suggests a renal problem or the action of a diuretic
     - urine [Na⁺] <20 mmol/L suggests a prerenal problem
  2. daily urinary potassium excretion rate should be decreased (<20 mmol/d) in hypokalemia
     - if higher than 20 mmol/d, suggests renal contribution to hypokalemia
- osmolality is useful to estimate the kidney's concentrating ability
- FENa refers to the fractional excretion of Na⁺
  - FENa <1% suggests the pathology is prerenal
- urine pH is useful to grossly assess renal acidification
  - low pH (<5.5) in the presence of low serum pH is an appropriate renal response
  - a high pH in this setting might indicate a renal acidification defect (e.g. RTA)

**Electrolyte Disorders**

**Sodium Homeostasis**
- hyponatremia and hypernatremia are disorders of water balance
  - hyponatremia usually suggests too much water in the ECF relative to Na⁺ content
  - hypernatremia usually suggests too little water in the ECF relative to Na⁺ content
- solutes (such as Na⁺, K⁺, glucose) that cannot freely traverse the plasma membrane contribute to effective osmolality and induce transcellular shifts of water
  - water moves out of cells in response to increased ECF osmolality
  - water moves into cells in response to decreased ECF osmolality
- ECF volume is determined by Na⁺ content rather than concentration
  - Na⁺ deficiency leads to ECF volume contraction
  - Na⁺ excess leads to ECF volume expansion
- clinical signs and symptoms of hyponatremia and hypernatremia are secondary to cells (especially in the brain) shrinking (hyponatremia) or swelling (hypernatremia)

</table>

*If there is a renal abnormality (e.g. osmotic diuresis), the urine output may be increased despite the presence of hypovolemia.

**Hyponatremia**

- hyponatremia: serum [Na+] <135 mmol/L
- can be associated with hypo-osmolality (most common), iso-osmolality, or hyperosmolality
- consider if it is “appropriate” vs. “inappropriate” ADH secretion
- if appropriate ADH secretion, is it real vs. effective volume loss?

**Figure 4. Approach to hyponatremia**

**Hypovolemic**

- $U_{osm}<20$ and $F_{Na}<1\%$ (renal losses)
- CHF
- Cirrhosis and ascites
- Nephrotic syndrome
- Pregnancy
- $U_{Na}>20$
- AKI, CKD

**Hypervolemic**

- $U_{osm}>100$
- SIADH (normal $U_{Na}$)
- Adrenal insufficiency
- Hypothyroidism
- $U_{Na}<100$
- Psychogenic polydipsia
- Low solute - “tea & toast”
- $U_{Na}>20$
- Diuretics (especially thiazides)
- Salt-wasting nephropathy
- Diarrhea
- Excessive sweating
- Third spacing (e.g. peritonitis, pancreatitis, burns)

**Iso-Osmolar**

- (280-295 mOsm/kg)
- Retention in ECF of large volumes of isotonic fluids that do not contain sodium (e.g. mannitol)
- Pseudohyponatremia – lab artifact seen with severe hyperlipidemia or paraproteinemia (e.g. multiple myeloma)

**Hypo-Osmolar (dilutional)**

- (<280 mOsm/kg)
- Most common cause of hyponatremia
- Excess water in relation to sodium stores which can be decreased, normal, or increased
- Categorized by volume status as determined by clinical assessment

**Hyper-Osmolar (translocational)**

- (>295 mOsm/kg)
- Extra osmoles in ECF draw water out of cells diluting the Na+ in ECF
- Usually glucose (rarely hypertonic mannitol)
- Every 10 mmol/L increase in blood glucose results in 3 mmol/L decrease in Na

**Symptoms of Central Pontine Myelinolysis**

- Cranial nerve palsies
- Quadriplegia
- Decreased LOC

**Complications**

- seizures, coma, respiratory arrest, permanent brain damage, brainstem herniation, death
- risk of brain cell shrinkage with rapid correction of hyponatremia
- can develop osmotic demyelination of pontine and extrapontine neurons; may be irreversible (e.g. central pontine myelinolysis: cranial nerve palsies, quadriplegia, decreased LOC)
Risk Factors for Osmotic Demyelination
- rise in serum [Na+] with correction >8 mmol/L/24 hr if chronic hyponatremia
- associated hypokalemia and/or malnutrition (e.g. low muscle mass)
- if patient with hyponatremia and hypovolemia is given large volume of isotonic fluid (ADH is stimulated by hypovolemia; when hypovolemia is corrected, the ADH level falls suddenly causing sudden brisk water diuresis, and therefore rapid rise in serum Na+ level)
- patient with psychogenic polydipsia, deprived of water

Investigations
- ECF volume status assessment (see Table 4)
- serum electrolytes, glucose, Cr
- serum osmolality, urine osmolality
- urine Na+ (urine Na+ < 10-20 mmol/L suggests volume depletion as the cause of hyponatremia)
- assess for causes of SIADH (see Table 5)
- TSH, free T4, and cortisol levels
- consider CXR and possibly CT chest if suspect pulmonary cause of SIADH (e.g. paraneoplastic syndrome by small cell lung cancer)
- consider CT head if suspect CNS cause of SIADH

Treatment of Hyponatremia
- general measures for all patients
  1. treat underlying cause (e.g. restore ECF volume if volume depleted, remove offending drug, treat pain, nausea, etc.)
  2. restrict free water intake
  3. promote free water loss
  4. carefully monitor serum Na+, urine volume, and urine tonicity
  5. ensure frequently that correction is not occurring too rapidly
     - monitor urine output frequently: high output of dilute urine is the first sign of dangerously rapid correction of hyponatremia

A. Known Acute (known to have developed over <24-48 h)
- commonly occurs in hospital (dilute IV fluid, post-operative increased ADH)
- less risk from rapid correction since adaptation has not fully occurred
- if symptomatic
  - correct rapidly with 3% NaCl 1-2 cc/kg/h up to serum [Na+] = 125-130 mmol/L
  - may need furosemide to address volume overload
- if asymptomatic, treatment depends on severity
  - if marked fall in plasma [Na+], treat as symptomatic

B. Chronic or Unknown
  1. if severe symptoms (seizures or decreased LOC)
     - must partially correct acutely
     - aim for increase of Na+ by 0.5-1 mmol/L/h for 4-6 h
     - limit total rise to 8 mmol/L in 24 h
     - IV 3% NaCl at 1-2 cc/kg/h
     - may need furosemide
  2. if asymptomatic
     - water restrict to <1 L/d fluid intake
     - consider IV 0.9% NS + furosemide (reduces urine osmolality augments excretion of H2O)
     - consider NaCl tablet or Oxo cubes® as a source of Na+
  3. refractory
     - furosemide and oral salt tablets
     - oral urea (osmotic aquaresis)
     - V2 receptor antagonists (e.g. tolvaptan)
  4. always pay attention to patient’s ECF volume status  if already volume-expanded, unlikely to give NaCl (tablet or IV); if already volume-depleted, almost never appropriate to give furosemide

C. Options for Treatment of Overly-Rapid Correction
- give water (IV D5W)
- give ADH to stop water diuresis (DDAVP 1-2 µg IV)

Impact of IV Solution on Serum [Na+] 
- formula to estimate the change in serum [Na+] caused by retention of 1 L of any infusate
  \[ \text{change in serum [Na+] = \text{infusate [Na+] - serum [Na+] \over TBW + 1 L}} \]
- formula assumes there are no losses of water or electrolytes
SYNDROME OF INAPPROPRIATE ANTIDIURETIC HORMONE SECRETION
1. urine that is inappropriately concentrated for the serum osmolality
2. high urine sodium (>20-40 mmol/L)
3. high FE\textsubscript{Na}

Hypernatremia

- hypernatremia: serum [Na\textsuperscript{+}] >145 mmol/L
- too little water relative to total body Na\textsuperscript{+}; always a hyperosmolar state
- usually due to NET water loss, rarely due to hypertonic Na\textsuperscript{+} gain
- less common than hyponatremia because patients are protected against hypernatremia by thirst and release of ADH

![Hypernatremia Diagram](image)

Figure 5. Approach to hypernatremia

**Signs and Symptoms**
- with acute hypernatremia there is no time for adaptation, therefore more likely to be symptomatic
- adaptive response: cells import and generate new osmotically active particles to normalize size
- due to brain cell shrinkage: altered mental status, weakness, neuromuscular irritability, focal neurologic deficits, seizures, coma, death
- ± polyuria, thirst, signs of hypovolemia

**Complications**
- increased risk of vascular rupture resulting in intracranial hemorrhage
- rapid correction may lead to cerebral edema due to ongoing brain hyperosmolality

**Treatment of Hypernatremia**
- general measures for all patients
  - give free water (oral or IV)
  - treat underlying cause
  - monitor serum Na\textsuperscript{+} frequently to ensure correction is not occurring too rapidly
- if evidence of hemodynamic instability, must first correct volume depletion with NS bolus
- loss of water is often accompanied by loss of Na\textsuperscript{+}, but a proportionately larger water loss
- use formula to calculate free water H\textsubscript{2}O deficit and replace
- encourage patient to drink pure water, as oral route is preferred for fluid administration

**H\textsubscript{2}O Deficit and TBW Equations**

\[
\text{H}_{2}\text{O deficit} = \text{TBW} \times (\text{Na}\textsuperscript{+}\text{plasma} - 140) / 140
\]

\[
\text{TBW} = 0.6 \times \text{wt (kg)} \quad \text{men}
\]

\[
\text{TBW} = 0.5 \times \text{wt (kg)} \quad \text{women}
\]

1 L 0.9% NS approximately equals 500 mL of free water
Electrolyte Disorders

• if unable to replace PO or NG, correct H₂O deficit with hypotonic IV solution (IV D5W, 0.45% NS [half normal saline], or 3.3% dextrose with 0.3% NaCl [1/2/3 and 1/3])
  • use formula (see Hyponatremia, NP8) to estimate expected change in serum Na⁺ with 1 L infusate
  • aim to lower [Na⁺] by no more than 12 mmol/L in 24 h (0.5 mmol/L/h)
  • must also provide maintenance fluids and replace ongoing losses
  • general rule: give 2 cc/kg/h of free water to correct serum [Na⁺] by about 0.5 mmol/L/h or 12 mmol/L/d

Diabetes Insipidus

• collecting tubule is impermeable to water due to absence of ADH or impaired response to ADH
• defect in central release of ADH (central DI) or renal response to ADH (nephrogenic DI)

Etiology

• central DI: neurosurgery, granulomatous diseases, trauma, vascular events, and malignancy
• nephrogenic DI: lithium (most common), hypokalemia, hypercalcemia, and congenital

Diagnosis

• urine osmolality inappropriately low in patient with hypernatremia (Uosm <300 mOsm/kg)
• serum vasopressin concentration may be absent or low (central), or elevated (nephrogenic)
• dehydration test: H₂O deprivation until loss of 3% of body weight or until urine osmolality rises above plasma osmolality; if urine osmolality remains <300 (fails to concentrate urine), most likely DI
• administer DDAVP (exogenous ADH) (10 µg intranasally or 2 µg SC or IV)
  • central DI: diagnosed if there is rise in urine osmolality, fall in urine volume
  • treat with DDAVP
  • nephrogenic DI: exogenous ADH fails to concentrate urine as kidneys do not respond
  • treat with water (IV D5W or PO water), thiazides may help as well (reduced ECF volume stimulates proximal tubular reabsorption of sodium and water, leading to less delivery of glomerular filtrate to ADH sensitive parts of renal tubule, and therefore lower urine volume results)

Potassium Homeostasis

• approximately 98% of total body K⁺ stores are intracellular
• normal serum K⁺ ranges from 3.5-5.0 mEq/L
• in response to K⁺ load, rapid removal from ECF is necessary to prevent life-threatening hyperkalemia
• insulin, catecholamines, and acid-base status influence K movement into cells
  • aldosterone has a minor effect
• potassium excretion is regulated at the distal nephron
  • K⁺ excretion = urine flow rate x urine [K⁺]

Factors which Increase Renal K⁺ Loss

• hyperkalemia
• increased distal tubular urine flow rate and Na⁺ delivery (thiazides and loop diuretics)
• increased aldosterone activates epithelial sodium channels in cortical collecting duct, causing Na⁺ reabsorption and K⁺ excretion
• metabolic alkalosis (increases K⁺ secretion)
• hypomagnesemia
• increased non-reabsorbable anions in tubule lumen: HCO₃⁻, penicillin, salicylate (increased tubular flow rate increases K⁺ secretion)

Hypokalemia

• serum [K⁺] <3.5 mEq/L

Signs and Symptoms

• usually asymptomatic, particularly when mild (3.0-3.5 mmol/L)
• N/V, fatigue, generalized weakness, myalgia, muscle cramps, and constipation
• if severe: arrhythmias, muscle necrosis, and rarely paralysis with eventual respiratory impairment
• arrhythmias occur at variable levels of K⁺; more likely if digoxin use, hypomagnesemia, or CAD
• ECG changes are more predictive of clinical picture than serum [K⁺]
  • U waves most important (low amplitude wave following a T wave)
  • flattened or inverted T waves
  • depressed ST segment
  • prolongation of Q T interval
  • sinus bradycardia
  • with severe hypokalemia: P-R prolongation, wide QRS, arrhythmias; increases risk of digitalis toxicity
• common arrhythmias seen with hypokalemia: Ventricular fibrillation, Ventricular tachycardia's
**Electrolyte Disorders**

**NP12 Nephrology**

**Toronto Notes 2018**

---

**Figure 6. ECG changes in hypokalemia**

**Approach to Hypokalemia**

1. emergency measures: obtain ECG; if potentially life threatening, begin treatment immediately
2. rule out transcellular shifts of $K^+$ as cause of hypokalemia
3. assess contribution of dietary $K^+$ intake
4. spot urine $K:Cr$ (should be less than 1 in setting of hypokalemia)
   - if <1 consider GI loss
   - if >1 consider a renal loss
5. consider 24 h $K^+$ excretion
6. if renal $K^+$ loss, check BP and acid-base status
7. may also assess plasma renin and aldosterone levels, serum $[Mg^{2+}]$

---

**Figure 7. Approach to hypokalemia**

**Treatment**

- treat underlying cause
- if true $K^+$ deficit, potassium repletion
  - oral sources – food, tablets (K-Dur®), KCl liquid solutions (preferable route if the patient tolerates PO medications)
  - IV – usually KCl in saline solutions, avoid dextrose solutions (may exacerbate hypokalemia via insulin release)
- max 40 mmol/L via peripheral vein, 60 mmol/L via central vein, max infusion 20 mmol/h
- $K^+$-sparing diuretics (triamterene, amiloride, spironolactone) can prevent renal $K^+$ loss
- restore $Mg^{2+}$ if necessary
- if urine output and renal function are impaired, correct with extreme caution
- risk of hyperkalemia with potassium replacement especially high in elderly, diabetics, and patients with decreased renal function
- use of ACE inhibitor or ARB for CHF (reduces angiotensin II action and therefore aldosterone)
- beware of excessive potassium repletion, especially if transcellular shift caused hypokalemia

---

**Figure 6**

**Hypokalemia**

1. Decreased Intake
   - Limited dietary intake
   - Clay ingestion
2. Increased Loss
   - Spot urine K:Cr
     - Spot urine K:Cr < 1
     - Spot urine K:Cr > 1
3. Redistribution into Cells (transcellular shifts)
   - Metabolic alkalosis ($K^+/H^+$ exchange across cell membrane)
   - Insulin (stimulates Na+/K+ ATPase)
   - Catecholamines, β₂-agonists (salbutamol), theophylline (stimulates Na+/K+ ATPase)
   - Tocolytic agents
   - Uptake into newly forming cells
     - Vitamin B₁₂ injections in pernicious anemia
     - Colony stimulating factors 
4. Hypo- or normotensive
   - Check acid base status
5. Hypertensive
   - 1º hyperaldosteronism (e.g. Conn’s syndrome)
   - 2º hyperaldosteronism (renovascular disease, renin tumour)
   - Non-aldosterone mineralocorticoid (Cushing’s, exogenous)
6. Acidemic
   - DKA
   - RTA
7. Variable
   - HypoK
   - Vomiting/NG
8. Alkalemic
   - Diuretics (furosemide, HCTZ) manifest as renal losses due to hyperaldosteronism, metabolic alkalosis and increased flow to collecting duct
   - Inherited renal tubular lesions
     - Barter’s (loop of Henle dysfunction: furosemide-like effect)
     - Gitelman’s (DCT dysfunction: thiazide-like)
Hyperkalemia

- serum \([K^+] >5.0 \text{ mEq/L}\)

Signs and Symptoms
- usually asymptomatic but may develop nausea, palpitations, muscle weakness, muscle stiffness, paresthesias, areflexia, ascending paralysis, and hypoventilation
- impaired renal ammoniagenesis and metabolic acidosis
- ECG changes and cardioxicity (do not correlate well with serum \([K^+]\))
- peaked and narrow T waves
- decreased amplitude and eventual loss of P waves
- prolonged PR interval
- widening of QRS and eventual merging with T wave (sine-wave pattern)
- AV block
- ventricular fibrillation, asystole

![Figure 8. ECG changes in hyperkalemia](image)

Approach to Hyperkalemia
1. emergency measures: obtain ECG, if life threatening begin treatment immediately
2. rule out factitious hyperkalemia; repeat blood test
3. hold exogenous K⁺ (PO and IV) and any K⁺ retaining medications
4. assess potential causes of transcellular shift
5. estimate GFR (calculate CrCl using Cockcroft-Gault)

Treatment
- acute therapy is warranted if ECG changes are present or if patient is symptomatic regardless of \([K^+]\)
- tailor therapy to severity of increase in \([K^+]\) and ECG changes
  - \([K^+] <6.5\) and normal ECG
    - treat underlying cause, stop K⁺ intake, increase the loss of K⁺ via urine and/or GI tract
  - \([K^+]\) between 6.5 and 7.0, no ECG changes: add insulin to above regimen
  - \([K^+] >7.0\) and/or ECG changes: first priority is to protect the heart, add calcium gluconate to above

1. Stabilize Myocardium
- calcium gluconate 1-2 amps (10 mL of 10% solution) IV
- antagonizes the membrane action of hyperkalemia, protects cardiac conduction system, no effect on serum \([K^+]\)
- onset within minutes, lasts 30-60 min (may require repeat doses during treatment course of hyperkalemia)
2. Shift K⁺ into Cells
- regular insulin (Insulin R) 10-20 units IV, with 1-2 amp D50W (give D50W before insulin)
  - onset of action 15-30 min, lasts 1-2 h
  - monitor capillary blood glucose q1h because of risk of hypoglycemia
  - can repeat every 4-6 h
  - caution giving D50W before insulin if hyperkalemia is severe as it can cause a serious arrhythmia
- NaHCO₃ 1-3 ampules (given as 3 ampules of 7.5% or 8.4% NaHCO₃ in 1L D5W)
  - onset of action 15-30 min, transient effect, drives K⁺ into cells in exchange for H⁺
  - more effective if patient has metabolic acidosis
- β₂-agonist (Ventolin⁺) in nebulized form (dose = 2 cc or 10 mg inhaled) or 0.5 mg IV
  - onset of action 30-90 min, stimulates Na⁺/K⁺ ATPase
  - caution if patient has heart disease as may result in tachycardia

3. Enhance K⁺ Removal from Body
- via urine (preferred approach)
  - furosemide (≥40 mg IV), may need IV NS to avoid hypovolemia
  - fludrocortisone (synthetic mineralocorticoid) if suspect aldosterone deficiency
- via gastrointestinal tract
  - cation exchange resins: calcium resonium or sodium polystyrene sulfonate (Kayexalate⁺)
    - increasingly falling out of favour due to risk of colonic necrosis; works by binding Na⁺ in exchange for K⁺, and controversial how much K⁺ is actually removed
  - lactulose or sorbitol PO to avoid constipation (must ensure that patient has a bowel movement after resin is administered - main benefit may be the diarrhea caused by lactulose)
  - Kayexalate⁺ enemas with tap water
- dialysis (renal failure, life threatening hyperkalemia unresponsive to therapy)

---

**Hyperphosphatemia**

**Definition**
- serum phosphate >1.45 mmol/L
- critical role in the development of secondary hyperparathyroidism and renal osteodystrophy in patients with advanced CKD and on dialysis

**Table 8. Etiology of Hyperphosphatemia**

<table>
<thead>
<tr>

<td></td>
<td></td>
</tr>
</tbody>
</table>

**Clinical Features**
- non-specific, include ectopic calcification, renal osteodystrophy

**Treatment**
- acute: hemodialysis if symptomatic; aluminum hydroxide (use with extreme caution in renal failure)
- chronic: low PO₄³⁻ diet, phosphate binders (e.g. CaCO₃ or lanthanum carbonate or sevelamer with meals)

---

**Hypophosphatemia**

**Definition**
- serum phosphate <0.85 mmol/L

**Clinical Features**
- non-specific (CHF, coma, hypotension, weakness, defective clotting)
Acid-Base Disorders

Treatment
- treat underlying cause
  - Oral PO$^43$ 2-4 g/d divided bid-qid (start at 1 g/d to minimize diarrhea)
  - IV PO$^43$: only for severely symptomatic patients or inability to tolerate oral therapy

Hypermagnesemia

Definition
- serum magnesium >0.85 mmol/L

Etiology
- AKI/CRF
- Mg$^{2+}$-containing antacids or enemas
- IV administration of large doses of MgSO$_4$ (e.g. for Preeclampsia; see Obstetrics, OB24)

Clinical Features
- rarely symptomatic
- drowsiness, hyporeflexia, respiratory depression, heart block, cardiac arrest, hypotension

Treatment
- discontinue Mg$^{2+}$-containing products
- IV calcium (Mg$^{2+}$-antagonist) for acute reversal of magnesium toxicity
- dialysis if renal failure

Hypomagnesemia

Definition
- serum magnesium <0.70 mmol/L

</tbody>
</table>

Clinical Features
- seizures, paresis, Chvostek and Trousseau signs, ECG changes (widened QRS, prolonged PR, T-wave abnormalities), and arrhythmias including Torsades de Pointes

Treatment
- treat underlying cause
- encourage increased dietary intake e.g. fruits
- oral Mg$^{2+}$ salts unless patient has seizures or other severe symptoms
- Mg$^{2+}$ IM/IV; cellular uptake of Mg$^{2+}$ is slow, therefore repletion requires sustained correction
- discontinue diuretics
  - in patients requiring diuretics, use a K$^+$-sparing diuretic to minimize magnesuria

Acid-Base Disorders
- acid-base homeostasis influences protein function and can critically affect tissue and organ function with consequences to cardiovascular, respiratory, metabolic, and CNS function
- see Respirology, R6 for more information on respiratory acidosis/alkalosis
- normal concentration of HCO$_3^-$ = 24 mEq/L (range: 22-30 mEq/L)
- normal pCO$_2$ = 40 mmHg (range: 36-44 mmHg)
- each acid base disorder has an appropriate compensation
  - inadequate compensation or overcompensation can indicate the presence of a second acid-base disorder (e.g. in metabolic acidosis, inadequate compensation means there is also respiratory acidosis; overcompensation means there is also respiratory alkalosis)
Acid-Base Disorders

Figure 9  Approach to acid-base disorders

**Approach**

1. **Identify the primary disturbance**
   - respiratory acidosis, metabolic acidosis, respiratory alkalosis, metabolic alkalosis

2. **Evaluate compensation. If compensation is not appropriate, a second acid-base disorder is likely present**
   - compensation occurs in the same direction as the primary disturbance

3. **Calculate Plasma AG**
   - AG = [Na+] – ([HCO3-] + [Cl–])
   - baseline = 12, normal range 10-14 mEq/L
   - AG can be altered by plasma albumin level: for each 10 g/L fall in albumin, lower baseline AG by 3 mEq/L (e.g. if plasma [albumin]= 20 g/L, expect AG = 6 mEq/L)

4. **If AG elevated, compare increase in AG with decrease in HCO3-**
   - if increase in AG < decrease in HCO3-, there is a coexisting non-AG metabolic acidosis
   - if increase in AG > decrease in HCO3-, there is a coexisting metabolic alkalosis

5. **Calculate Osmolar Gap**
   - osmolar gap = measured osmolality – calculated osmolality
   - calculated osmolality = (2 x [Na+]) + [urea] + [glucose] (all units are in mmol/L)
   - calculated osmolality <10
   - if OG >10, consider: methanol poisoning, ethylene glycol poisoning, or another cause of acidosis plus ethanol ingestion

**Metabolic Acidosis**

**Etiology and Pathophysiology**

1. **Increased AG Metabolic Acidosis (4 types)**
   - L-lactic acidosis (2 types)
     - type A: due to tissue hypoperfusion (any cause of shock), ischemic bowel, profound hypoxemia
     - type B: non-hypoxic – multiple causes; the most common is failure to metabolize normally produced lactic acid in the liver due to severe liver disease; other causes include: excessive alcohol intake, thiamine deficiency, metformin accumulation (metformin interferes with electron transport chain), certain anti-retrovirals, large tumours, mitochondrial myopathies
     - D-lactic acid: rare syndrome characterized by episodes of encephalopathy and metabolic acidosis
     - occurs in the setting of carbohydrate malabsorption (e.g. short bowel syndrome), colonic bacteria metabolize carbohydrate load into D-lactic acid, diminished colonic motility and impaired D-lactate metabolism
   - diabetic
   - starvation
   - alcoholic (decreased carbohydrate intake and vomiting)

   **Useful Equations**
   - AG = [Na+] - ([HCO3-] + [Cl–]) (normal range = 10-14 mEq/L)
   - Osmolar Gap = measured serum osmolality – calculated osmolality (normal <10 mEq/L)
   - calculated osmolality = (2 x [Na+]) + [urea] + [glucose] + [Ethanol] (all units are in mmol/L)

   **Causes of Increased AG Metabolic Acidosis**
   - Methanol
   - Ethylene glycol
   - Ethanol
   - Polyethylene glycol
   - Mannitol
   - Sorbitol
3. toxins
   • methanol (toxic to brain and retina, can cause blindness and brain death): metabolized to formic acid
   • ethylene glycol (toxic to brain and kidneys): metabolized to oxalic acid (envelope shaped crystals in urine) and multiple other acids
   • salicylate (e.g. ASA) overdose: causes acidosis due to salicylic acid, and also accumulation of lactic acid (salicylate at toxic levels impairs electron transport chain) and ketoacid (salicylate activates fat breakdown)

4. advanced renal failure (e.g. serum Cr increased at least 5x above baseline – a very low GFR causes anion retention, and renal disease leads to impaired bicarbonate production)

2. Normal AG Metabolic Acidosis (Hyperchloremic Acidosis)
   • diarrhea (HCO₃⁻ loss from GI tract)
   • RTA
     ◆ type I RTA (distal): inability to secrete H⁺ in collecting duct, leading to impaired excretion of ammonium into urine
     ◆ type II RTA (proximal): impaired HCO₃⁻ reabsorption
     ◆ type III RTA: combination of Types I and II and is extremely rare
     ◆ type IV RTA: defective ammoniagenesis due to decreased aldosterone, hyporesponsiveness to aldosterone, or hyperkalemia
   • to help distinguish renal causes from non-renal causes, use Urine AG = (Na⁺ + K⁺) – Cl⁻
   • calculation establishes the presence or absence of unmeasured positive ions (e.g. NH₄⁺) in urine
     ◆ if UAG <0, suggests adequate NH₄⁺ excretion in urine (likely nonrenal cause: diarrhea)
     ◆ if UAG >0, suggests problem is lack of NH₄⁺ in urine (e.g. distal RTA)

Treatment of Metabolic Acidosis
1. treat underlying cause:
   • fluid resuscitation and insulin for DKA
   • restore tissue perfusion for Type A lactic acidosis
   • ethanol/fomepizole ± dialysis for methanol or ethylene glycol poisoning
   • alkaline diuresis ± dialysis if ASA overdose
2. correct coexisting disorders of K⁺ (see Hyperkalemia, NP13)
3. consider treatment with exogenous alkali (e.g. NaHCO₃) if:
   • severe reduction in [HCO₃⁻] e.g. <8 mmol/L, especially with very low pH (<7)
   • no metabolizable anion (e.g. salicylate, formate, oxalate, or sulphate); note that lactate and ketoacid anions can be metabolized to HCO₃⁻
   • note: risks of sodium bicarbonate therapy
     ◆ hypokalemia: causes K⁺ to shift into cells (correct K⁺ deficit first)
     ◆ ECF volume overload: Na⁺ load given with NaHCO₃ can exacerbate pulmonary edema
     ◆ overshoot alkalemia: abrupt, poorly tolerated transition from overly aggressive alkali loading, partial conversion of accumulated organic anions to HCO₃⁻, and persisting hyperventilation

Metabolic Alkalosis

Pathophysiology
   • requires initiating event and maintenance factors
   • precipitating factors
     ◆ GI (vomiting, NG tube) or renal loss of H⁺
     ◆ exogenous alkali (oral or parenteral administration), milk alkali syndrome
     ◆ diuretics (contraction alkalosis): decreased excretion of HCO₃⁻, decreased ECF volume, therefore increased [HCO₃⁻]
     ◆ post-hypercapnia: renal compensation for respiratory acidosis is HCO₃⁻ retention, rapid correction of respiratory disorder results in transient excess of HCO₃⁻
   • maintenance factors
     ◆ volume depletion: reduced GFR and increase proximal reabsorption of NaHCO₃ and increased aldosterone
     ◆ hyperaldosteronism (1º or 2º): distal Na⁺ reabsorption in exchange for K⁺ and H⁺ excretion leads to HCO₃⁻ generation; aldosterone also promotes hypokalemia
     ◆ hypokalemia: transcellular K⁺/H⁺ exchange, stimulus for ammoniagenesis and HCO₃⁻ generation

Evaluate Compensation (identify co-existing respiratory acid-base disorders)
   • hypoventilation (an upper limit to compensation exists – breathing cannot be stopped)

Treatment
   • treat underlying cause
   • correct underlying disease, replenish K⁺ and Mg²⁺ deficits, and possibly K⁺-sparing diuretic
   • saline sensitive metabolic alkalosis (most common)
     ◆ volume repletion ± carbonic anhydrase inhibitor (e.g. acetazolamide) to facilitate loss of HCO₃⁻ in urine
   • saline resistant metabolic alkalosis
     ◆ remove source of aldosterone or glucocorticoid ± spironolactone

Causes of Non-AG Metabolic Acidosis

HARDUP
   • Hyperalimentation
   • Acetazolamide
   • RTA *
   • Diarrhea *
   • Ureterointestinal fistula
   • Pancreaticoduodenal fistula

*Most common
**Acute Kidney Injury**

**Definition**
- abrupt decline in renal function leading to increased nitrogenous waste products normally excreted by the kidney
- formerly known as acute renal failure

**Clinical Presentation**
- azotemia (increased BUN, Cr)
- abnormal urine volume: formally <0.5 ml/kg/h for >6 h but can manifest as anuria, oliguria, or polyuria

**Approach to AKI**

**Investigations**
- blood work: CBC, electrolytes, Cr, urea (think prerenal if increase in urea is relatively greater than increase in Cr), Ca²⁺, PO₄³⁻
- urine dipstick: albumin, hemoglobin, WBC's, others: glucose, pH, urobilinogen, specific gravity
- urine volume. C&S, R&M: sediment, casts, crystals
- urinary indices: electrolytes, osmolality
- Foley catheterization (rule out bladder outlet obstruction)

**Clues to Prerenal Etiology**
- Clinical: Decreased BP, increased HR, and orthostatic HR and BP changes
- Increased [urea] >> Increased [Cr]
- Urine (Na⁺) <10-20 mmol/L
- Urine osmolality >500 mOsm/kg
- Fractional excretion of Na⁺ <1%

**Clues to Renal Etiology**
- Appropriate clinical context
- Urinalysis positive for casts:
  - Pigmented granular – ATN
  - WBC – AIN
  - RBC – GN
- Systemic features, anemia, thrombocytopenia, HTN, mild-moderate ECF volume overload

**Clues to Postrenal Etiology**
- Known solitary kidney
- Older man
- Recent retroperitoneal surgery
- Anuria
- Palpable bladder
- Ultrasound shows hydronephrosis

**Differentiating Prerenal from ATN**

<table>

Parenchymal Kidney Diseases

• fluid challenge (e.g. fluid bolus to rule out most prerenal causes)
• imaging: abdomen U/S (assess kidney size, hydronephrosis, postrenal obstruction)
• indications for renal biopsy
  • diagnosis is not certain
  • prerenal azotemia or ATN is unlikely
  • oliguria persists > 2-4 days

Treatment
1. preliminary measures
   ■ prerenal
     • correct prerenal factors: optimize volume status and cardiac performance using fluids that will stay in the plasma subcompartment (NS, albumin, blood/plasma), hold ACEI/ARB (gently rehydrate when needed, e.g. CHF) and NSAIDs
   ■ renal
     • address reversible renal causes: discontinue nephrotoxic drugs, treat infection, and optimize electrolytes
     • correct ECF volume, supportive care, consider corticosteroid or immunosuppressive therapy
   ■ postrenal
     • consider obstruction: structural (stones, strictures) vs. functional (neuropathy)
     • for obstruction to cause AKI, must have functional solitary kidney or obstruction affecting both kidneys:
       treat with Foley catheter insertion, indwelling bladder catheter, nephrostomy, stenting
2. treat complications
   ■ fluid overload
     • NaCl restriction
     • high dose loop diuretics
     • hyperkalemia (see Approach to Hyperkalemia, NP13)
     • adjust dosages of medications cleared by kidney (e.g. amiodarone, digoxin, cyclosporin, tacrolimus, some antibiotics, and chemotherapeutic agents)
   ■ dialysis
3. definitive therapy depends on etiology

Prognosis
• high morbidity and mortality in patients with sustained AKI and multi-organ failure

Parenchymal Kidney Diseases

Glomerular Diseases

HISTOLOGICAL TERMS OF GLOMERULAR CHANGES

Extent of Changes
• histological term describing the number of glomeruli affected in a given condition:
  ■ diffuse: majority of glomeruli abnormal
  ■ focal: some glomeruli affected
• histological term describing the extent to which individual glomeruli are affected in a given condition
  ■ global: entire glomerulus abnormal
  ■ segmental: only part of the glomerulus abnormal

Types of Changes
• proliferation: hyperplasia of one of the glomerular cell types (mesangial, endothelial, parietal epithelial), with or without inflammatory cell infiltration
• crescent formation: parietal epithelial cell proliferation and mononuclear cell infiltration form crescent-shape in Bowman’s space
• membranous changes: capillary wall thickening due to immune deposits or alterations in basement membrane

CLINICAL PRESENTATION OF GLOMERULAR DISEASE

Important Points to Remember
• glomerular diseases have diverse clinical presentations including hematuria, proteinuria, HTN, edema, and decreased GFR
• each glomerulopathy presents as one of four major glomerular syndromes (these are NOT diagnoses)
  1. asymptomatic urinary abnormalities
     - proteinuria
     - hematuria
  2. nephritic syndrome
     - acute GN
     - rapidly progressive GN
  3. nephrotic syndrome
  4. ESRD

Avoid NSAIDs in patients with diarrhea, heart failure or renal failure
Renal transplant is not a therapy for AKI
Drugs Implicated in Prerenal Azotemia
  • Diuretics
  • NSAIDs
  • ACEI/ARBs
• glomerulopathies can be caused by a primary disease or can occur secondary to a systemic disease
• some glomerulopathies can present as more than one syndrome at different times

The Nephritic-Nephrotic Spectrum
• glomerular pathology can present with a clinical picture anywhere on a spectrum with pure nephritic and pure nephrotic syndromes at the extremes

PROTEINURIA
• hallmark of nephrotic syndromes
• composition of normal urine protein: albumin, lower molecular proteins (such as immunoglobulin light chain) or proteins secreted by the tubular epithelial cells (e.g. Tamm-Horsfall mucoprotein)
• 24 h urine protein: gold standard to assess degree of proteinuria
• urine ACR: used to screen for diabetic nephropathy
• microalbuminuria: ACR ≥2.0mg/mmol
  • marker of vascular endothelial function
  • an important prognostic marker for kidney disease in DM and HTN (see Diabetes, NP31)
  • microalbuminuria is the earliest sign of diabetic nephropathy
• composition of normal total urine protein
• upper limit of normal daily excretion of total protein is 150 mg/d
• upper limit of normal daily excretion of albumin is 30 mg/d
• the other normally excreted proteins are either filtered low molecular weight proteins (such as immunoglobulin light chains or β-2 microglobulin) or proteins secreted by the tubular epithelial cells (e.g. Tamm-Horsfall mucoprotein)

Pathologic Proteinuria
Tubulointerstitial
• Normally low molecular weight proteins (<60 kDa) pass through glomerular filtration barrier and are reabsorbed in proximal tubule
• Proximal tubule dysfunction causes impaired reabsorption and increased excretion of low molecular weight proteins
• Albumin (>60 kDa) is not affected; thus, edema is partly secondary to salt and water retention

Glomerular
• Normally, the filtration barrier is selectively permeable to size (<60 kDa) and charge (repels negative particles); thus, albumin is filtered to a very limited extent through a normal glomerulus
• Damage to any component of the glomerular filtration barrier results in loss of albumin and other high molecular weight proteins; thus, edema is secondary to hypoalbuminemia (low oncotic pressure), but also due to enhanced renal tubular reabsorption of filtered sodium and water (possibly due to filtered proteins stimulating the action of cortical collecting duct epithelial sodium channel)

Overflow
• Increased production of low molecular weight proteins which exceeds the reabsorptive capacity of the proximal tubule
• Plasma cell dyscrasias: produce light chain Ig (multiple myeloma, Waldenstrom’s macroglobulinemia, monoclonal gammopathy of undetermined significance)
Table 10. Daily Excretion of Protein

<table>
<thead>
<tr>
<th>Daily Excretion</th>
<th>Stage of Nephropathy</th>

Investigations
- urine R&M, C&S, urea, Cr
- further workup (if degree of proteinuria >0.5 g/d, casts, and/or hematuria)
  - CBC, glucose, electrolytes, 24 h urine protein, and Cr
  - urine and serum immunoelectrophoresis, abdominal/pelvic U/S
  - serology: ANA, RF, p-ANCA (MPO), c-ANCA (PR3), Hep B, Hep C, HIV, ASOT
- indications for nephrology referral
  - generally if there is "heavy" proteinuria (ACR >30 mg/mmol), should refer to nephrologist
  - definitely if there is nephrotic syndrome: marked proteinuria >3.5 g/1.73m²/d with hypoalbuminemia (<35 g/L)

HEMATURIA
- hallmark of nephritic syndromes
- presence of blood or RBCs in urine
  - gross hematuria: pink, red, or tea-coloured urine
    - if the sediment is red, true hematuria
    - if the supernatant is red, test for heme with a dipstick
    - if supernatant positive for heme: myoglobinuria or hemoglobinuria
    - if negative for heme; pseudohematuria; consider medications (e.g. rifampin), food dyes (e.g. beets), or metabolites (e.g. porphyria)
  - microscopic hematuria: blood in the urine that is invisible to the naked eye, >2-3 RBCs/HPF on microscopy

Figure 14. Approach to red urine

Investigations for Hematuria
- Hx and P/E: family history of nephrolithiasis, hearing loss (Alport Syndrome), cerebral aneurysm (PCKD), diet, recent URTI, irritative and obstructive urinary symptoms (UTI)
- urine R&M, C&S, urea, Cr
- renal U/S
- 24 h urine stone workup if there is a history of stone formation or if there is a stone noted on imaging: calcium, oxalate, titrate, magnesium, uric acid, cystine
- further workup (if casts and/or proteinuria): CBC, electrolytes, 24 h urine protein and Cr, serology (ANA, RF, C3, C4, p-ANCA, c-ANCA, ASOT)
- consider urology consult and possible cystoscopy if not clearly a nephrologic source for hematuria or if >50 yr of age
**Glomerular Syndromes**

### 1. ASYMPTOMATIC URINARY ABNORMALITIES

**Clinical/Lab Features**
- often have rapid decline in GFR, anemia, elevated inflammatory markers, ECF volume replete or mildly overloaded
  - proteinuria (usually <2 g/d) and/or microscopic or macroscopic hematuria
    - isolated proteinuria
      - can be postural
      - occasionally can signal beginning of more serious GN (e.g. FSGS, IgA nephropathy, amyloid, diabetic nephropathy)
    - hematuria with or without proteinuria
      - IgA nephropathy (Berger's disease): most common type of primary glomerular disease worldwide, usually presents after viral URTI
      - hereditary nephritis (Alport Syndrome – Type IV collagen mutation): X-linked nephritis often associated with sensorineural hearing loss; proteinuria <2 g/d
      - benign thin basement membrane disease: usually autosomal dominant, without proteinuria; benign
      - benign recurrent hematuria: hematuria associated with febrile illness, exercise, or immunization; a diagnosis of exclusion after other possibilities are ruled out

### 2 NEPHRITIC SYNDROME

#### Anti-GBM Mediated (RPGN Type I) (15%)
- Linear IF pattern due to IgG and C3 deposition along capillary loops
- anti-GBM +ve
- With lung hemorrhage: Goodpasture's disease
- Without lung hemorrhage: Anti-GBM disease

#### Immune Complex Mediated (RPGN Type II) (24%)
- Granular pattern due to subendothelial or subepithelial deposits of IgG and C3
- C3 normal
- IgA nephropathy
- Henoch-Schönlein purpura
- Membranoproliferative GN
- SLE
- Infective endocarditis
- Post-infectious GN
- Cryoglobulinemia
- c-ANCA +ve
- Granulomatosis with polyangiitis

#### Non-Immune Mediated (RPGN Type III) (60%)
- Pauci-immune: no immune staining
- Decreased C3
- p-ANCA +ve
- Churg-Strauss
- Microscopic polyangiitis

#### Double Antibody Positive Disease (RPGN Type IV)
- Has features of Type I and Type III
- Double antibody positive

---

**Figure 15. Approach to nephritic syndrome**

**ACUTE NEPHRITIC SYNDROME**
- a subset of nephritic syndrome in which the clinical course proceeds over days
- etiology can be divided into low and normal complement levels
- frequently immune-mediated, with Ig and C3 deposits found in GBM

**Clinical/Lab Features**
- proteinuria (but <3.5 g/1.73 m²/d)
- abrupt onset hematuria (microscopic or macroscopic)
- azotemia (increased Cr and urea)
- RBC casts and/or dysmorphic RBCs in urine
- oliguria, HTN (due to salt and water retention)
- peripheral edema/puffy eyes
- smoky urine

**Treatment**
- depends on etiology
- pulse steroid therapy and other immunosuppression, BP control, monitoring for progression to end stage renal disease

**RAPIDLY PROGRESSIVE GLOMERULONEPHRITIS**
- a subset of nephritic syndrome in which the clinical course proceeds over weeks to months
- clinical diagnosis, not histopathological
- any cause of GN can present as RPGN (except minimal change disease)
- additional etiologies seen only as RPGN: anti-GBM Disease and granulomatosis with polyangiitis (previously called Wegener's granulomatisis)
- crescentic GN (identified by pathology) results from proliferation of parietal epithelial cells and is the most aggressive form of glomerular disease
**Clinical/Lab Features**
- Fibrous crescents typically present on renal histopathology
- RBC casts and/or dysmorphic RBCs in urine
- Classified by immunofluorescence staining
- Type I: Anti-GBM mediated (15% of cases)
- Type II: Immune complex mediated (24% of cases)
- Type III: Non-immune mediated (60% of cases)
- Type IV: Double antibody positive

**Treatment and Prognosis**
- Treatment: underlying cause for postinfectious; corticosteroids + cyclophosphamide or other cytotoxic agent + plasmapheresis in management of cases such as Anti-GBM Ab
- Prognosis: 50% recovery with early treatment, depends on underlying cause

**3. NEPHROTIC SYNDROME**

**Clinical/Lab Features**
- Heavy proteinuria (>3.5 g/1.73 m²/d)
- Hypoalbuminemia
- Edema
- Hyperlipidemia (elevated LDL cholesterol), lipiduria (fatty casts and oval fat bodies on microscopy)
- Hypercoagulable state (due to antithrombin III, Protein C, and protein S urinary losses)
- Patient may report frothy urine
- Glomerular pathology on renal biopsy
  - Minimal change disease (or minimal lesion disease or nil disease) – e.g. glomeruli appear normal on light microscopy
  - Membranous glomerulopathy
  - Focal segmental glomerulosclerosis (FSGS)
  - Membranoproliferative GN
  - Nodular glomerulosclerosis
- Each can be idiopathic or secondary to a systemic disease or drug (sirolimus can cause proteinuria without obvious glomerular pathology)

**Table 11. Nephrotic Syndrome**

**4. END STAGE RENAL DISEASE**
- See *End Stage Renal Disease*, NP36

**INVESTIGATIONS FOR GLOMERULAR DISEASE**
- Blood work
  - First presentation: electrolytes, Cr, urea, albumin, fasting lipids
  - Determining etiology: CBC, ESR, serum immunoelectrophoresis, anti-GBM Disease, C3, C4, ANA, p-ANCA, c-ANCA, cryoglobulins, HBV and HCV serology, ASOT (anti-streptolysin titres), VDRL, HIV
- Urinalysis: RBCs, WBCs, casts, protein
- 24 h urine for protein and CrCl
- Radiology
  - CXR (infiltrates, CHF, pleural effusion)
  - Renal US
- Renal biopsy (percutaneous or open) if heavy proteinuria or renal insufficiency and cause is not obviously diabetic nephropathy
- Urine immunoelectrophoresis
  - For Bence-Jones protein if proteinuria present
SECONDARY CAUSES OF GLOMERULAR DISEASE

Amyloidosis
- nodular deposits of amyloid in mesangium, usually related to amyloid light chain (AL)
- presents as nephrotic range proteinuria with progressive renal insufficiency
- can be primary or secondary
- secondary causes: multiple myeloma, TB, rheumatoid arthritis, malignancy

Systemic Lupus Erythematosus (see Rheumatology, RH11)
- lupus nephritis can present as any of the glomerular syndromes
- nephrotic syndrome with an active sediment is most common presentation
- GN caused by immune complex deposition in capillary loops and mesangium with resulting renal injury
- serum complement, ANA, anti-DNA levels are usually low during periods of active renal disease
- children and males with SLE are more likely to develop nephritis

Henoch-Schönlein Purpura
- seen more commonly in children
- purpura on buttocks and legs, abdominal pain, arthralgia, and fever
- IgA and C3 staining of mesangium
- usually benign, self-limiting course, 10% progress to CKD

Anti-GBM Disease
- Goodpasture Syndrome when lung and renal both involved
- antibodies against type IV collagen present in lungs and GBM
- present with RPGN type I and hemoptysis/dyspnea
- pulmonary hemorrhage more common in smokers and males
- treat with plasma exchange, cyclophosphamide, prednisone

ANCA Associated Vasculitis
- c-ANCA most commonly associated with the clinical picture of granulomatosis with polyangiitis
- p-ANCA most commonly associated with the clinical picture of microscopic polyangiitis
- focal segmental necrotizing RPGN with no immune staining
- may be indolent or fulminant in progression
- vasculitis and granulomas rarely seen on renal biopsy
- treatment typically involves cyclophosphamide and prednisone

Cryoglobulinemia
- cryoglobulins: monoclonal IgM and polyclonal IgG which precipitate at reduced temperatures
- presents as purpura, fever, Raynaud’s phenomenon, and arthralgias
- at least 50% of patients have hepatitis C
- renal disease seen in 40% of patients (isolated proteinuria/hematuria progressing to nephritic syndrome)
- most patients have decreased serum complement (C4 initially)
- treat hepatitis C, plasmapheresis
- overall prognosis: 75% renal recovery

Figure 16. International Society of Nephrology/Renal Pathology Society classification of lupus nephritis 2003

Henoch-Schönlein Purpura
- seen more commonly in children
- purpura on buttocks and legs, abdominal pain, arthralgia, and fever
- IgA and C3 staining of mesangium
- usually benign, self-limiting course, 10% progress to CKD
Shunt Nephritis
- immune-complex mediated nephritis associated with chronically infected ventriculoatrial shunts inserted for treatment of hydrocephalus
- presents as acute nephritic syndrome with decreased serum complement
- nephrotic range proteinuria in 25% of patients
- treat by removing shunt and administering appropriate antibiotics

HIV-Associated Renal Disease
1. direct nephrotoxic effect of HIV infection, anti-retroviral drugs (e.g. tenofovir, indinavir), and other drugs used to treat HIV-associated infections
2. HIV-associated nephropathy
   - histology: focal and segmental glomerular collapse with mesangial sclerosis; “collapsing FSGS”
   - tubular cystic dilation and tubulo-reticular inclusions
   - clinical features: predominant in African American men, heavy proteinuria, progressive renal insufficiency (apo-l-1 risk genotypes)
   - prognosis: kidney failure within 1 yr without treatment
   - therapy: short term, high dose steroids, ACEI, HAART

Infective Endocarditis
- manifests as mild form of acute nephritic syndrome with decreased serum complement
- S. aureus is most common infecting agent
- treatment with appropriate antibiotics usually resolves GN

Hepatitis B
- can result in membranous nephropathy, polyarteritis nodosa, membranoproliferative GN

Hepatitis C
- can result in membranous nephropathy, cryoglobulinemia, and membranoproliferative GN

Syphilis
- can result in membranous GN

Tubulointerstitial Disease

TUBULOINTERSTITIAL NEPHRITIS

Definition
- cellular infiltrates affecting primarily the renal interstitium and tubular cells
- functional tubule defects are disproportionately greater than the decrease in GFR
- classified as acute or chronic

Signs and Symptoms
- manifestation of disease depends on site of tubule affected
  1. proximal tubule (e.g. multiple myeloma, heavy metals)
     - Fanconi syndrome: decreased reabsorption in proximal tubule causing glycosuria, aminoaciduria, phosphaturia, hyperuricosuria
     - proximal RTA (decreased bicarbonate absorption): Type II RTA
  2. distal tubule (e.g. amyloidosis, obstruction)
     - distal RTA (Type I RTA), usually hypokalemic
     - Na+-wasting nephropathy
     - ± hyperkalemia leading to type IV RTA (where reduced renal bicarbonate production is caused by hyperkalemia)
  3. collecting duct (e.g. sickle cell anemia, analgesics, PCKD)
     - urinary concentrating defect leading to mild nephrogenic DI
     - polyuria

1 ACUTE TUBULOINTERSTITIAL NEPHRITIS

Definition
- rapid (days to weeks) decline in renal function
- 10-20% of all AKI

Etiology
- hypersensitivity
  1. antibiotics: β-lactams, sulfonamides, rifampin, quinolones, cephalosporins, fluoroquinolones
  2. other: NSAIDs, allopurinol, furosemide, thiazides, triamterene, PPIs, acyclovir, phenytoin, cimetidine
Parenchymal Kidney Diseases

• infections
  • immune
    • SLE, acute allograft rejection, Sjögren’s syndrome, sarcoidosis, mixed essential cryoglobulinemia
  • idiopathic

Pathophysiology
• acute inflammatory cell infiltrates into renal interstitium

Clinical Features
• AKI
  • if hypersensitivity reaction: may see fever, skin rash, arthralgia, serum sickness-like syndrome (particularly rifampin)
  • if pyelonephritis: flank pain and costovertebral angle (CVA) tenderness
  • if drug reaction, AKI usually occurs 7-10 days after exposure
  • other signs and symptoms based on underlying etiology
  • HTN and edema are uncommon

Findings
• urine
  • mild, non-nephrotic range proteinuria and microscopic hematuria
  • sterile pyuria, WBC casts
  • eosinophilia if AIN
• blood work
  • increased Cr and urea
  • eosinophilia if drug reaction
  • normal AG metabolic acidosis (RTA)
  • hypophosphatemia, hyperkalemia, hyponatremia
  • gallium scan often shows intense signal due to inflammatory infiltrate
  • renal biopsy definitive

Treatment
• treat underlying cause (e.g. stop offending medications, antibiotics if pyelonephritis)
• corticosteroids (may be indicated in allergic or immune disease)

Prognosis
• recovery within 2 wk if underlying insult can be eliminated
• the longer the patient is in renal failure, the less likely they will have a full renal recovery

2. CHRONIC TUBULOINTERSTITIAL NEPHRITIS

Definition
• characterized by slowly progressive renal failure, moderate proteinuria, and signs of abnormal tubule function

Etiology
• persistence or progression of acute TIN
• urinary tract obstruction: most important cause of chronic TIN (tumours, stones, bladder outlet obstruction, vesicoureteral reflux)
• chronic pyelonephritis due to vesicoureteral reflux or UTI with obstruction
• nephrotoxins
  • exogenous
    • analgesics: NSAIDs (common), acetaminophen
    • cisplatin, lithium, cyclosporine, tacrolimus
    • heavy metals (lead, cadmium, copper, lithium, mercury, arsenic)
    • Chinese herbs (aristolochic acid)
  • endogenous
    • hypercalcemia, hypokalemia, oxalate, uric acid
• vascular disease: ischemic nephrosclerosis, atheroembolic disease
• malignancies: multiple myeloma, lymphoma
• granulomatous: TB, sarcoidosis granulomatosis with polyangiitis
• immune: SLE, Sjögren’s, cryoglobulinemia, Anti-GBM Disease, amyloidosis, renal graft rejection, vasculitis
• hereditary: cystic diseases of the kidney, sickle cell disease
• others: radiation, Balkan (endemic) nephropathy

Pathophysiology
• fibrosis of interstitium with atrophy of tubules, mononuclear cell inflammation

Signs and Symptoms
• dependent on underlying etiology
**Findings**
- normal AG metabolic acidosis
- hyperkalemia (out of proportion to degree of renal insufficiency)
- polyuria, nocturia
- partial or complete Fanconi's syndrome
- progressive renal failure with azotemia and uremia
- urine: mild proteinuria, few RBCs and WBCs, no RBC casts
- U/S: shrunken kidneys with irregular contours

**Treatment**
- stop offending agent or treat underlying disease
- supportive measures: correct metabolic disorders (Ca\(^{2+}\), PO\(_{4}^{3-}\)) and anemia

### 3. ACUTE TUBULAR NECROSIS

**Definition**
- abrupt and sustained decline in GFR within minutes to days after ischemic/nephrotoxic insult
- GFR reduced (this serves the purpose of avoiding life-threatening urinary loss of fluid and electrolytes from non-functioning tubules)

**Clinical Presentation**
- typically presents as an acute rise in urea and Cr after a hypotensive episode, sepsis, rhabdomyolysis, or administration of nephrotoxic drug
- most common cause of non-prerenal AKI in hospitalized patients
- urine: high FE\(_{\text{Na}}\), pigmented-granular casts

**Risk Factors**
- pre-existing chronic kidney disease, pre-existing cardiovascular disease, ECF volume depletion, multiple renal insults

**Complications**
- hyperkalemia: can occur rapidly and cause serious arrhythmias
- metabolic acidosis, decreased Ca\(^{2+}\), increased PO\(_{4}^{3-}\), hypoalbuminemia

**Investigations**
- blood work: CBC, electrolytes, Cr, urea, Ca\(^{2+}\), PO\(_{4}^{3-}\), blood gases
- urine: R&M, electrolytes, osmolality, microscopic urinalysis searching for pigmented granular casts
- ECG
- abdominal U/S
- rule out other causes of prerenal/postrenal azotemia and intrinsic AKI (GN, AIN, vasculitis)

**Treatment**
- largely supportive once underlying problem is corrected
- loop diuretics may help manage volume overload and reduce tubular metabolic requirements to allow for recovery (controversial)
- consider early dialysis in severe/rapidly progressing cases to prevent uremic syndrome

---

**Figure 17. Etiology of ATN**

**Etiology**
- Acute Tubular Necrosis
  - **Toxins**
    - Exogenous
      - Antibiotics
        - Aminoglycosides
        - Cephalosporins
        - Amphotericin B
    - Antiviral (cidofovir)
    - Antineoplastics
      - Cisplatin
      - Methotrexate
    - Contrast media
    - Heavy metals
    - Other
      - Fluorinated anesthetic
      - Ethylene glycol
  - Endogenous
    - Endotoxins (bacterial)
    - Myoglobin
    - Hemoglobin
  - Decreased Circulating Volume
    - Hemorrhage including post-surgical
    - Skin losses
    - GI losses
    - Renal losses
    - Decreased Effective Circulating Volume
      - Heart failure
      - Liver failure
      - Sepsis
      - Anaphylaxis
    - Vessel Occlusion
      - Large or small renal artery involvement

---

**Meta-Analysis: Effectiveness of Drugs for Preventing Contrast-Induced Nephropathy**

- **Ann Intern Med** 2008; 148: 84-96
- **Purpose**: To determine the effectiveness of N-acetyl cysteine, theophylline, fenoldopam, dopamine, lisinopril, statin, furosemide, or mannitol on preventing nephropathy.
- **Study Selection**: RCTs that used these agents in patients receiving iodinated contrast.
- **Results**: In the 41 RCTs included, N-acetyl cysteine (RR=0.62 [0.44-0.88]) and theophylline (RR=0.49 [0.25-0.92]) reduced the risk of nephropathy more than saline alone. Furosemide increased the risk (RR=3.27 [1.48-7.26]). Other agents did not affect risk of nephropathy.
- **Conclusion**: N-acetyl cysteine is more renoprotective than hydration alone.
Prevention
- correct fluid balance before surgical procedures
- for patients with chronic renal disease requiring radiographic contrast:
  - give N-acetylcysteine 600-1200 mg PO bid before and day of procedure, give intravenous isotonic fluid (either NaCl or NaHCO₃)
  - isotonic NaHCO₃ at 3 mL/kg over 1 h before procedure and 1 mL/kg/h for 6 h post-procedure if not contraindicated
  - avoid giving diuretics, ACEI, cyclosporine on morning of procedure if possible
- use renal-adjusted doses of nephrotoxic drugs in patients with renal insufficiency

Vascular Diseases of the Kidney

</tbody>
</table>

1. RENAL INFARCTION (ACUTE RENAL ARTERY OCCLUSION)
- important, potentially reversible cause of renal failure

Etiology
- abdominal trauma, surgery, embolism, vasculitis, extra-renal compression, hypercoagulable state, aortic dissection
- kidney transplant recipients more vulnerable

Signs and Symptoms (depend on presence of collateral circulation)
- fever, N/V, flank pain
- leukocytosis, elevated AST, ALP
- marked elevated LDH (LDH >4x upper limit of normal with minimal elevations in AST/ALT strongly suggestive)
- acute onset HTN (activation of RAAS) or sudden worsening of long-standing HTN
- renal dysfunction, e.g. elevated Cr (if bilateral, or solitary functioning kidney)

Investigations
- renal arteriography (more reliable but risk of atheroembolic renal disease)
- contrast-enhanced CT or MR angiography, duplex Doppler studies (operator dependent)

Treatment
- prompt localization of occlusion and restoration of blood flow
- anticoagulation thrombolysis, percutaneous angioplasty or clot extraction, surgical thrombectomy
- medical therapy in the long-term to reduce risk (e.g. antihypertensives)

2. ISCHEMIC RENAL DISEASE (RENAral Artery STenosis)
- chronic renal impairment secondary to hemodynamically significant renal artery stenosis or microvascular disease
- significant cause of ESRD: 15% in patients >50 yr (higher prevalence if significant vascular disease)
- usually associated with large vessel disease elsewhere
- causes of renal artery stenosis
  - atherosclerotic plaques (90%): proximal 1/3 renal artery, usually males >55 yr, smokers
  - fibromuscular dysplasia (10%): distal 2/3 renal artery or segmental branches, usually young females (typical onset <30 yr)
- when there is decreased RBF, GFR is dependent on angiotensin II-induced efferent arteriolar constriction which raises the FF (GFR/RBF)
- most common cause of secondary HTN (“renovascular HTN”), 1-2% of all hypertensive patients
- etiology
  - decreased renal perfusion of one or both kidneys leads to increased renin release and subsequent angiotensin production
  - increased angiotensin raises blood pressure in two ways
    1. causes generalized arteriolar constriction
    2. release of aldosterone increases Na⁺ and water retention
- elevated blood pressure can in turn lead to further damage of kidneys and worsening HTN
# Risk Factors
- >50 yr
- smoking
- other atherosclerotic disease (dyslipidemia, DM, diffuse atherosclerosis)

# Signs and Symptoms
- severe/refractory HTN and/or hypertensive crises, with negative family history of HTN
- asymmetric renal size
- epigastric or flank bruits
- spontaneous hypokalemia (renin activation in under-perfused kidney)
- increasing Cr with ACEI/ARB
- flash pulmonary edema with normal LV function

# Investigations
- must establish presence of renal artery stenosis and prove it is responsible for renal dysfunction
- duplex Doppler U/S (kidney size, blood flow): good screening test (operator dependent)
- digital subtraction angiography (risk of contrast nephropathy)
- CT or MR angiography (effective noninvasive tests to establish presence of stenosis, for MR avoid gadolinium contrast if eGFR <30 mL/min because of risk of systemic dermal fibrosis)
- ACEI renography (e.g. captopril renal scan)
- renal arteriography (gold standard)

# Treatment
- surgical: percutaneous angioplasty ± stent, surgical revascularization, occasionally surgical bypass
- medical: BP lowering medications (ACEI is drug of choice if unilateral renal artery disease but contraindicated if bilateral renal artery disease)
- little or no benefit if therapy is late (e.g. kidney is already shrunken), however, therapy can be considered to save the opposite kidney if normal

### 3. RENAL VEIN THROMBOSIS

#### Etiology
- hypercoagulable states (e.g. nephrotic syndrome, especially membranous), ECF volume depletion, extrinsic compression of renal vein, significant trauma, malignancy (e.g. RCC), sickle cell disease
- clinical presentation determined by rapidity of occlusion and formation of collateral circulation

#### Signs and Symptoms
- acute: N/V, flank pain, hematuria, elevated plasma LDH, ± rise in Cr, sudden rise in proteinuria
- chronic: PE (typical first presenting symptom), increasing proteinuria and/or tubule dysfunction

#### Investigations
- renal venography (gold standard), CT or MR angiography, duplex Doppler U/S

#### Treatment
- thrombolytic therapy ± percutaneous thrombectomy for acute renal vein thrombosis
- anticoagulation with heparin then warfarin (1 yr or indefinitely, depending on risk factors)

### MEDIUM VESSEL DISEASE

1. **KAWASAKI DISEASE**
   - see Pediatrics, P87

2. **POLYARTERITIS NODOSA**
   - see Rheumatology, RH19
   - kidneys most commonly involved organ
   - heterogenous impact on renal function
   - pathologically can cause glomerular ischemia which manifests as mild proteinuria and hypertension

### SMALL VESSEL DISEASE

1. **HYPERTENSIVE NEPHROSCLEROSIS**
   - see Hypertension, NP35

2. **ATHEROEMBOLIC RENAL DISEASE**
   - progressive renal insufficiency due to embolic obstruction of small- and medium-sized renal vessels by atheromatous emboli
   - spontaneous or after renal artery manipulation (surgery, angiography, percutaneous angioplasty)
• anticoagulants and thrombolytics interfere with ulcerated plaque healing and can worsen disease
• investigations
  • cosinophilia, eosinophiluria, and hypocomplementemia
  • ren 1 biopsy: needle-shaped cholesterol clefts (due to tissue-processing artifacts) with surrounding tissue reaction in small-/medium-sized vessels
• treatment
  • no effective treatment; avoid angiographic and surgical procedures in patients with diffuse atherosclerosis, medical therapy for concomitant cardiovascular disease
  • prognosis: poor overall, at least one third will develop ESRD

3. THROMBOTIC MICROANGIOPATHY
  • see Hematology, H22
  • etiologies include the spectrum of TTP-HUS, DIC, severe preeclampsia
  • renal involvement more common in HUS than TTP
  • renal involvement characterized by fibrin thrombi in glomerular capillary loops ± arterioles
  • treatment
    • depends on cause
    • supportive therapy
    • TTP-HUS: plasma exchange, corticosteroids (splenectomy and rituximab if refractory)
  • avoid platelet transfusions and ASA

4. CALCINEURIN INHIBITOR NEPHROPATHY
  • cyclosporine and tacrolimus
  • causes both acute reversible and chronic, largely irreversible nephrotoxicity
  • major cause of kidney failure in other solid organ transplants (e.g. heart)
  • acute: due to afferent and efferent glomerular capillary constriction leading to decreased GFR (tubular vacuolization)
  • preglomerular azotemia
  • treatment: calcium channel blockers or prostaglandin analogs, reduce dose of cyclosporine or switch to another immunosuppressive drug
  • chronic: result of obliterator arteriopathy causing interstitial nephritis and CKD (striped fibrosis), less frequent now due to lower doses of calcineurin inhibitors

### Analgesic Nephropathies

1. Vasomotor AKI
   • clinically: develop preglomerular azotemia within a few days of starting NSAID
   • normally prostaglandins vasodilate afferent renal arteriole to maintain blood flow
   • NSAIDs act by blocking cyclooxygenase enzyme, thereby preventing prostaglandin synthesis and causing renal ischemia
   • more common in elderly, underlying renal disease, hypovolemia (diuretics, CHF, cirrhosis, nephrotic syndrome)
   • treatment: discontinue NSAID, dialysis rarely needed

2. Acute Interstitial Nephritis
   • fenoprofen (60%), ibuprofen, naproxen
   • may be associated with minimal change glomerulopathy and nephrotic range proteinuria
   • resolves eventually with discontinuation of NSAID, may require interval dialysis
   • short-term high dose steroids (1 mg/kg/d of prednisone) may hasten recovery

3. Chronic Interstitial Nephritis
   • due to excessive consumption of antipyretics (phenacetin or acetaminophen) in combination with NSAIDs
   • seen in patients who also have emotional stress, psychiatric symptoms, and GI disturbance
   • papillary necrosis
     • gross hematuria, flank pain, declining renal function
     • calyceal filling defect seen with IVP – “ring sign”
   • increased risk of transitional cell carcinoma of renal pelvis
   • good prognosis if discontinue analgesics

4. Acute Tubular Necrosis
   • can be caused by acetaminophen
   • incidence of renal dysfunction is related to the severity of acetaminophen ingestion
   • vascular endothelial damage can also occur
   • both direct toxicity and ischemia contribute to the tubular damage
   • renal function spontaneously returns to baseline within 1–4 wk
   • dialysis may be required during the acute episode of ingestion

5. Other Effects of NSAIDs
   • sodium retention (2° to reduced GFR)
   • hyperkalemia, HTN (2° to hyporeninemic hypoaldosteronism)
   • excess water retention (2° to loss of antagonistic effect of prostaglandins on ADH)
Systemic Disease with Renal Manifestation

Diabetes

- diabetic nephropathy: presence of microalbuminuria or overt nephropathy (e.g. macroalbuminuria) in patients with DM who lack indicators of other renal diseases
- most common cause of end-stage renal failure in North America
- 50% of patients with diabetes will develop nephropathy
- at diagnosis up to 30% of patients with type 2 DM have albuminuria (75% microalbuminuria, 25% overt nephropathy)
- microalbuminuria is a risk factor for progression to overt nephropathy and cardiovascular disease
- once macroalbuminuria is established, renal function declines, 50% of patients reach ESRD within 7-10 yr
- associated with HTN and diabetic retinopathy (especially type 1 DM) and/or neuropathy (especially type 2 DM)
- indication of possible non-diabetic cause of renal disease in patients with DM
  - rising Cr with little/no proteinuria
  - lack of retinopathy or neuropathy (microvascular complications)
  - persistent hematuria (microscopic or macroscopic)
  - signs or symptoms of systemic disease
  - inappropiate time course; rapidly rising Cr, renal disease in a patient with short duration of DM
  - family history of non-diabetic renal disease (e.g. PCKD, Alport’s)

DIABETIC RENAL COMPLICATIONS

1. Progressive Glomerulosclerosis
   - classic diabetic glomerular lesion: Kimmelstiel-Wilson nodular glomerulosclerosis (15-20%)
   - more common lesion is diffuse glomerulosclerosis with a uniform increase in mesangial matrix

<table>
<thead>
<tr>
<th>Table 13. Stages of Diabetic Progressive Glomerulosclerosis</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stage 1</td>
</tr>
<tr>
<td>---------</td>

</tr>
<tr>
<td>(ACR) 2.0-20 mg/mmol (18-180 mg/d)</td>
</tr>
<tr>
<td>↑ mesangial matrix</td>
</tr>
<tr>
<td>↑↑↑ mesangial matrix</td>
</tr>
</tbody>
</table>

2. Accelerated Atherosclerosis
   - common finding
   - decreased GFR
   - may increase angiotensin II production resulting in increased BP
   - increased risk of ATN secondary to contrast media

3. Autonomic Neuropathy
   - affects bladder leading to functional obstruction and urinary retention
   - residual urine promotes infection
   - obstructive nephropathy

4. Papillary Necrosis
   - type 1 DM susceptible to ischemic necrosis of medullary papillae
   - sloughed papillae may obstruct ureter
   - can present as renal colic or with obstructive features ± hydronephrosis
Figure 19. Clinical practice guidelines on chronic kidney disease in diabetes

Priorities in the Management of Patients with DM
1. vascular protection for all patients with DM
   • ACEI, antiplatelet therapy (as indicated)
   • BP control, glycemic control, lifestyle modification, lipid control
   • Canagliflozin provides renoprotection independent of its glycemic effects
2. optimization of BP in patients who are hypertensive
   • treat according to HTN guidelines
3. renal protection for DM patients with nephropathy (even in absence of HTN)
   • type 1 DM: ACEI or ARB
   • type 2 DM: CrCl >60 mL/min: ACEI or ARB – CrCl <60 mL/min: ARB
   • 2nd line agents: nondihydropyridine calcium channel blockers (diltiazem verapamil)
   • combination of ACEI and ARB not recommended for proteinuria
   • check serum Cr and K+ levels within 1 wk of initiating ACEI or ARB and at time of acute illness
   • serum Cr can safely be allowed to rise up to 30% with initiation of ACEI or ARB, usually stabilizes after 2-4 wk, monitor for significant worsening of renal function or hyperkalemia
   • if >30% rise in serum Cr or hyperkalemia, discontinue medication and consider 2nd line agent
   • consider holding ACEI, ARB, and/or diuretic with acute illness and in women before becoming pregnant
   • consider referral to nephrologist if ACR >60 mg/mmol, eGFR <30 mL/min, progressive kidney function loss, unable to achieve BP targets, or unable to stay on ACEI or ARB

Scleroderma
• see Rheumatology, RH13
• 50% of scleroderma patients have renal involvement (mild proteinuria, high Cr, HTN)
• renal involvement usually occurs early in the course of illness
• histology: media thickened, “onion skin” hypertrophy of small renal arteries, fibrinoid necrosis of afferent arterioles and glomeruli
• 10-15% of scleroderma patients have a “scleroderma renal crisis” (occurs in first few years of disease): malignant HTN, ARE, microangiopathy, volume overload, visual changes, HTN encephalopathy
• treatment: BP control with ACEI slows progression of renal disease

Renal Outcomes with Telmisartan, Ramipril, or Both in People at High Vascular Risk (ONTARGET Study)
Lancet 2008;372:547-553
Study: Prospective, multicentre, double-blind, RCT.
Participants: 25,620 patients with median follow-up of 56 mo.
Intervention: Patients received either ramipril (10 mg/d; n=8,576), telmisartan (80 mg/d; n=8,542), or a combination of both drugs (n=8,502).
Primary Outcome: Composite of dialysis, doubling of creatinine level, and death.
Results: The number of outcome events was similar for telmisartan (n=1,147) and ramipril (1,150; HR 1.00, 95% CI 0.92-1.09), but was increased with combination therapy (1,233; HR 1.09, 1.01-1.18, p=0.037). The need for dialysis or doubling of serum creatinine, was similar with telmisartan (189) and ramipril (174; HR 1.09, 0.89-1.34) and more frequent with combination therapy (212; HR 1.24, 1.01-1.51, p=0.038). Estimated GFR declined least with ramipril compared with telmisartan or combination therapy (p<0.001). The increase in urinary albumin excretion was less with telmisartan (p=0.004) and combination therapy (p<0.001) than with ramipril.
Conclusion: Renal outcomes were similar in both telmisartan and ramipril monotherapy. Combination therapy reduced proteinuria to a greater extent than monotherapy, but was associated with poorer renal outcomes.

Order random urine ACR and serum creatinine for eGFR
Screen annually when no transient causes of albuminuria or low eGFR are present, and when acute kidney injury or non-diabetic kidney disease is not suspected
Type 1 diabetes: Annually in postpubertal individuals with duration of diabetes ≥5 years
Type 2 diabetes: At diagnosis and annually thereafter

Chronic Kidney Disease Diagnosed
## Multiple Myeloma

- see Hematology, H49
- malignant proliferation of plasma cells in the bone marrow with the production of immunoglobulins
- patients may present with severe bone disease and renal failure
- light chains are filtered at the glomerulus and appear as Bence-Jones proteins in the urine (monoclonal light chains)
- kidney damage can occur by several mechanisms
  - hypercalcemia
  - light chain cast nephropathy or "myeloma kidney"
  - hyperuricemia
  - infection
  - secondary amyloidosis
  - monoclonal Ig deposition disease
  - diffuse tubular obstruction
- light chain cast nephropathy
  - large tubular casts in urine sediment (light chains + Tamm-Horsfall protein)
  - proteinuria and renal insufficiency, can progress rapidly to kidney failure
- monoclonal Ig deposition disease
  - deposits of monoclonal Ig in kidney, liver, heart, and other organs
  - mostly light chains (85-90%)
  - causes nodular glomerulosclerosis (similar to diabetic nephropathy)
- lab features: increased BUN, increased Cr, urine protein immunoelectrophoresis positive for Bence-Jones protein (not detected on urine dipstick)
- poor candidates for kidney transplantation

## Malignancy

- cancer can have many different renal manifestations
- kidney transplantation cannot be performed unless malignancy is cured
  - solid tumours: mild proteinuria or membranous GN
  - lymphoma: minimal change GN (Hodgkin's) or membranous GN (non-Hodgkin's)
  - renal cell carcinoma
  - tumour lysis syndrome: hyperuricemia, diffuse tubular obstruction, hyperkalemia, hyperphosphatemia, hypocalcemia, lactic acidosis
  - chemotherapy (especially cisplatin): ATN or chronic TIN
  - pelvic tumours/mets: postrenal failure secondary to obstruction
  - amyloidosis
  - radiotherapy (radiation nephritis)

## Chronic Kidney Disease

### Definition
- progressive abnormalities of kidney function for >3 months, with either
  - GFR <60 mL/min/1.73 m²; or
  - markers of kidney damage, including
  - albuminuria; or
  - small shrunken kidney <9 cm with increased cortical echogenicity on ultrasound; or
  - pathology on biopsy

### Clinical Features
- volume overload and HTN
- electrolyte and acid-base balance disorders (e.g. metabolic acidosis)
- uremia (e.g. nausea/vomiting, pruritus, encephalopathy)
- anemia
- bone mineral disorders

The numbers in the boxes are a reflection of the risk of progression and are a guide to the frequency of monitoring/year.

Management of Chronic Kidney Disease

- **diet**
  - preventing HTN and volume overload
  - Na⁺ and water restriction
  - preventing electrolyte imbalances
  - K⁺ restriction (40-60 mmol/d)
  - PO₄³⁻ restriction (1 g/d)
  - avoid extra-dietary Mg²⁺ (e.g. antacids)
  - preventing uremia and potentially delaying decline in GFR
  - protein restriction with adequate caloric intake in order to limit endogenous protein catabolism

- **medical**
  - adjust dosages of renally excreted medications
  - HTN: ACEI (target 140/90 mmHg without DM and 130/80 mmHg with DM), loop diuretics when GFR <25 mL/min
  - dyslipidemia: statins (target LDL <2 mmol/L)
  - calcium and phosphate disorders
    - calcium supplements (e.g. TUMS®) treats hypocalcemia when given between meals and binds phosphate when given with meals
    - consider calcitriol (1,25-dihydroxy-vitamin D) if hypocalcemic, but hold if hyperphosphatemic (reduces PTH)
    - sevelamer (phosphate binder) if both hypercalcemic and hyperphosphatemic
    - cinacalcet for hyperparathyroidism (sensitizes parathyroid to Ca²⁺, decreasing PTH)
  - metabolic acidosis: sodium bicarbonate
  - anemia: erythropoietin injections for Hb <90 g/L (9 g/dL) and target Hb between 90-105 g/L (9-10.5 g/dL)
  - clotting abnormalities: DDAVP if patient has clinical bleeding or invasive procedures (acts to reverse platelet dysfunction)

- **dialysis** (hemodialysis, peritoneal dialysis)
  - indications include persistent and refractory hyperkalemia or metabolic acidosis, fluid overload, encephalopathy, persistent nausea and vomiting, evidence of malnutrition, pericarditis
  - renal transplantation for end stage kidney disease

Prevention of Progression

- as above
  - control of HTN, DM (HbA1c <7%), cardiovascular risk factors (e.g. smoking cessation, physical activity, weight loss)
  - avoid nephrotoxins such as NSAID’s, COXIB’s, IV contrast in patients with eGFR < 60 mL/min/1.73 m²
  - address reversible causes of AKI
Hypertension

- see Family Medicine, FM34
- HTN occurs in about 20% of population
- etiology classified as primary (‘essential’; makes up 90% of cases) or secondary
- primary HTN can cause kidney disease (hypertensive nephrosclerosis), which may in turn exacerbate the HTN
- secondary HTN can be caused by renal parenchymal or renal vascular disease

Hypertensive Nephrosclerosis

Table 15. Chronic vs. Malignant Nephrosclerosis

</tbody>
</table>

Renovascular Hypertension

- see Vascular Diseases of the Kidney, NP28

Renal Parenchymal Hypertension

- HTN secondary to GN, AIN, diabetic nephropathy, or any other chronic renal disease
- mechanism of HTN not fully understood but may include:
  - excess RAAS activation due to inflammation and fibrosis in multiple small intra-renal vessels
  - production of unknown vasopressors, lack of production of unknown vasodilators, or lack of clearance of endogenous vasopressor
  - ineffective sodium excretion with fluid overload

Investigations

- as well as investigations for renovascular HTN, additional tests may include
  - 24 h urinary estimations of CrCl and protein excretion
  - imaging (U/S, CT)
  - serology for collagen-vascular disease
  - renal biopsy (very rarely if at all)

Treatment

- most chronic renal disease is irreversible, but treatment of HTN can slow the progression of renal insufficiency
- control ECF volume: Na⁺ restriction (2 g/d intake), diuretic, dialysis with end-stage disease
- ACEI or ARB may provide added benefit (monitor K⁺ and Cr) if there is significant proteinuria (>300 mg/d)

Cystic Diseases of the Kidney

- characterized by epithelium-lined cavities filled with fluid or semisolid debris within the kidneys
- includes: simple cysts (present in 50% of population >50), medullary cystic kidney, medullary sponge kidney, polycystic kidney disease (autosomal dominant and recessive), and acquired cystic kidney disease (in chronic hemodialysis patients)

Adult Polycystic Kidney Disease

- autosomal dominant; at least 2 genes: PKD1 (chr 16p) and PKD2 (chr 4q)
- PKD1 (1:400), PKD2 (1:1,000) accounts for about 10% of cases of renal failure
- patients generally heterozygous for mutant PKD gene but accumulate a series of second ‘somatic hits’ precipitating the condition
- PKD gene defect leads to abnormal proliferation and apoptosis of tubular epithelial cells leading to cyst growth

Hypercalcemia complicates many cancers and can cause multiple kinds of renal disorders (renal vasoconstriction with reduced GFR, salt-wasting with volume depletion, risk of calcium kidney stones)
Cystic Diseases of the Kidney

• most common extrarenal manifestations: multiple asymptomatic hepatic cysts (33%), mitral valve prolapse (25%), cerebral aneurysm (10%), diverticulosis
• polycystic liver disease rarely causes liver failure
• less common extrarenal manifestations: cysts in pancreas, spleen, thyroid, ovary, seminal vesicles, and aorta

Signs and Symptoms
• often asymptomatic; discovered incidentally on imaging or by screening those with FHx
• acute abdominal flank pain/dull lumbar back pain
• hematuria (frequently initial sign is microscopic hematuria, otherwise gross hematuria)
• nocturia (urinary concentrating defect)
• rarely extra-renal presentation (e.g. ruptured berry aneurysm, diverticulitis)
• HTN (increased renin due to focal compression of intrarenal arteries by cysts) (60-75%)
• ± palpable kidneys

Common Complications
• urinary tract and cyst infections, HTN, chronic renal failure, nephrolithiasis (5-15%), flank and chronic back pain

Clinical Course
• polycystic changes are always bilateral and can present at any age
• clinical manifestations rare before age 20-25
• kidneys are normal at birth but may enlarge to 10x normal size
• variable progression to renal functional impairment (ESRD in up to 50% by age 60)

Investigations
• radiographic diagnosis: best accomplished by renal U/S (enlarged kidneys, multiple cysts throughout renal parenchyma, increased cortical thickness, splaying of renal calyces)
• CT abdo with contrast (for equivocal cases, occasionally reveals more cystic involvement)
• gene linkage analysis for PKD1 for asymptomatic carriers
• Cr, BUN, urine R&M (to assess for hematuria)

Treatment
• goal: to preserve renal function by prevention and treatment of complications
• educate patient and family about disease, its manifestations, and inheritance pattern
• genetic counselling: transmission rate 50% from affected parent
• prevention and early treatment of urinary tract and cyst infections (avoid instrumentation of GU tract)
• TMP/SMX, ciprofloxacin: able to penetrate cyst walls, achieve therapeutic levels
• adequate hydration to prevent stone formation
• avoid contact sports due to greater risk of injury to enlarged kidneys
• screen for cerebral aneurysms if family history of aneurysmal hemorrhages
• monitor blood pressure and treat HTN with ACEI
• dialysis or transplant for ESRD (disease does not recur in transplanted kidney)
• may require nephrectomy for symptomatic relief of pain or due to recurrent infections

Autosomal Recessive Polycystic Kidney Disease

• 1:20,000 incidence
• prenatal diagnosis by enlarged kidneys
• perinatal death from respiratory failure
• patients who survive perinatal period develop CHF, HTN, CKD
• treated with dialysis, kidney and/or liver transplant

Medullary Sponge Kidney

• common, autosomal dominant, usually diagnosed in 4th-5th decades
• multiple cystic dilatations in the collecting ducts of the medulla
• renal stones, hematuria, and recurrent UTIs are common features
• an estimated 10% of patients who present with renal stones have medullary sponge kidney
• nephrocalcinosis on abdominal x-ray in 50% patients, often detect asymptomatic patients incidentally
• diagnosis: contrast filled medullary cysts on IVP leading to characteristic radial pattern (“bouquet of flowers”), “Swiss cheese” appearance on histological cross-section
• treat UTIs and stone formation as indicated
• does not result in renal failure
End Stage Renal Disease

ESRD represents an irreversible decline in kidney function requiring renal replacement therapy

Presentation of End Stage Renal Disease

1. Volume Overload
   • due to increase in total body Na⁺ content
   • signs: weight gain, HTN, pulmonary or peripheral edema

2. Electrolyte Abnormalities
   • high
     • K⁺ (decreased renal excretion, increased tissue breakdown)
     • PO₄³⁻ (decreased renal excretion, increased tissue breakdown)
     • Ca²⁺ (rare; happens during recovery phase after rhabdomyolysis-induced AKI or in settings where hypercalcemia contributes to renal failure, such as in multiple myeloma or sarcoidosis)
     • uric acid
   • low
     • Na⁺ (failure to excrete excessive water intake)
     • Ca²⁺ (decreased Vitamin D activation, hyperphosphatemia, hypoalbuminemia)
     • HCO₃⁻ (especially with sepsis or severe heart failure)

3. Uremic Syndrome
   • manifestations result from retention of urea and other metabolites as well as hormone deficiencies

Figure 20. Signs and symptoms of end stage renal disease

Complications

• CNS: decreased LOC, stupor, seizure
• CVS: cardiomyopathy, CHF, arrhythmia, pericarditis, atherosclerosis
• GI: peptic ulcer disease, gastroduodenitis, AVM
• hematologic: anemia, bleeding tendency (platelet dysfunction), infections
• endocrine
  • decreased testosterone, estrogen, progesterone
  • increased FSH, LH
• metabolic
  • renal osteodystrophy: secondary increased PTH due to decreased Ca²⁺, high PO₄³⁻, and low active vitamin D
  • osteitis fibrosa cystica
  • hypertriglyceridemia, accelerated atherogenesis
  • decreased insulin requirements, increased insulin resistance
• dermatologic: pruritus, ecchymosis, hematoma, calciphylaxis (vascular Ca²⁺ deposition)
Renal Replacement Therapy

Indications for Dialysis in Chronic Kidney Disease

*Unresponsive to medications

- hemodialysis: blood is filtered across a semipermeable membrane removing accumulated toxic waste products, solutes, excess fluid (ultrafiltration), and restoring buffering agents to the bloodstream
  - available as intermittent (e.g. 3-6x/wk) continuous (CVVHD) or sustained low efficiency (SLED)
  - can be delivered at home or in-centre, nocturnal
  - vascular access can be achieved through a central line, an artificial graft, or an AV fistula
- patients with CKD should be referred for surgery to attempt construction of a primary AV fistula when their eGFR is <20 mL/min, the serum Cr level quoted as >350 µmol/L, or within 1 yr of an anticipated need
- peritoneal dialysis: peritoneum acts as a semipermeable membrane similar to hemodialysis filter
  - advantages: independence, fewer stringent dietary restrictions, better rehabilitation rates
  - available as continuous ambulatory (CAPD; 4-5 exchanges per day) or cyclic (CCPD; machine carries out exchanges overnight)
  - refer patients with chronic renal disease to a nephrologist early on to facilitate treatment and plan in advance for renal replacement therapy (RRT)

MUST BE INDIVIDUALIZED

How to Write Dialysis Orders

- Filter Type (e.g. F80)
- Length (e.g. 4 h 3x/wk or 2 h daily)
- Q Blood Flow (max 500 cc/min)
- Ultrafiltration (e.g. 2 L or to target dry weight)
- Na+ (~140 can be adjusted by starting at 155 and “ramping” down to minimize cramping)
- K+ (based on serum K+’)
  - Serum K+: Dialysate
    - 4.6: 1.5
    - 3.5-4: 2.5
    - <3.5: 3.5
- Ca2+: 1.25
- HCO3–: 40
- Heparin (none, tight [500 U/h] or full [1000 U/h])
- N fluid to support BP (e.g. NS)

When to Initiate Dialysis

- Ccr < 20 mL/min
- Educate patient regarding dialysis; if not a candidate for peritoneal dialysis, make arrangements for AV fistula
- Ccr < 15 mL/min
- Weigh risk and benefits for initiating dialysis
- Ccr < 10 mL/min
- Dialysis should be initiated

NOTE
- Cockcroft-Gault equation (or MDRD equation) should be used to measure kidney function
- Monitor for uremic complications
- Significant benefits in quality of life can occur if dialysis started before Ccr < 15 mL/min
- It is unclear whether patients who start dialysis early have increased survival
- A preemptive transplant can be considered if patient is stable, in order to avoid dialysis

Commonly Used Immunosuppressive Drugs

- Calcineurin inhibitors
  - Cy Isoporne
  - Tacrolimus
- Anti-proliferative medications
  - Mycophenolate mofetil
  - Azathioprine
- Other agents
  - Sirolimus
  - Prednisone
- Anti-lymphocyte antibodies
  - Thymoglobulin
  - Basiliximab

Indications for Dialysis

- (refractory to medical therapy)
  - Acute Kidney Injury
    - Acute tubular necrosis
    - Prerenal azotemia
  - Chronic Kidney Disease
    - Anemia
    - Hypertension
    - Uremia
    - Uremic pericarditis
    - Pruritus
Renal Transplantation

- provides maximum replacement of GFR
- preferred modality of RRT in CKD, not AKI
  - best way to reverse uremic signs and symptoms
- renal transplantation has been shown to have improved long-term patient survival and greater quality of life over dialysis
- native kidneys usually left in situ
- 2 types: deceased donor, living donor (related or unrelated)
- living donor transplants have been shown to have better outcomes than deceased donor transplants
- kidney transplanted into iliac fossa, transplant renal artery anastomosed to external iliac artery of recipient
- 1 yr renal allograft survival rates ≥90%

Complications

- #1 cause of mortality in transplanted patients is cardiovascular disease
- de novo GN (usually membranous)
- new-onset DM (often due to prednisone and calcineurin inhibitors, especially tacrolimus)
- graft rejection
- acute rejection: graft site tenderness, rise in Cr, oliguria, ± fever, although symptoms are uncommon
- early allograft damage caused by episodes of acute rejection and acute peritransplant injuries
- transplant glomerulopathy from antibody injury causes nephrotic proteinuria
- cyclosporine or tacrolimus nephrotoxicity (see Small Vessel Disease, NP29)
- BK virus (polyoma virus) nephropathy can result from over-immunosuppression and lead to graft loss
- leading causes of late allograft loss: interstitial fibrosis/tubular atrophy (IFTA) and death with functioning graft
- depends on immunologic and nonimmunologic factors (HTN, hyperlipidemia, age of donor, quality of graft, new onset DM)
- infections (CMV, PJP and other opportunistic infections usually occur between 1 and 6 mo post-transplant)
- malignancy (skin cancer, Kaposi’s sarcoma, non-Hodgkin’s lymphoma)

Survival Benefit with Kidney Transplants from HLA-Incompatible Live Donors

NEJM 2016;374:940-950

Purpose: To assess whether there is a survival advantage to receiving a kidney from HLA-incompatible donors compared to remaining on the waiting list for a possible matched deceased donor kidney.

Study: Retrospective, multi-centre analysis

Population: 10,205 individuals who received HLA-incompatible live donor kidneys compared to two different controls: individuals waiting and possibly receiving a deceased donor kidney (N=5125), or individuals ultimate y no receiving a kidney transplant (N=5125).

Outcome: Survival, tracked for up to 8 years.

Results: Individuals who received HLA-incompatible kidneys had increased survival compared to either control group for time points at 1 year, 5 years, and 8 years post-transplant (p<0.001). After 8 years non-matched kidney recipients had 76.5% survival compared to 43.9% for individuals who ultimately did not receive a kidney transplant. Survival advantage was significant regardless of how the recipient anti-HLA antibodies were detected.

Conclusions: Individuals who received HLA-incompatible kidneys had significantly improved long-term survival compared to individuals who waited for compatible deceased donor kidneys.

Common Medications

- Osmotic Diuretics
  - mannitol (Osmolite®, Osmolyte®)
  - glycerol ura
  - provides maximum replacement of GFR
  - preferred modality of RRT in CKD, not AKI
  - best way to reverse uremic signs and symptoms
  - renal transplantation has been shown to have improved long-term patient survival and greater quality of life over dialysis
  - native kidneys usually left in situ
  - 2 types: deceased donor, living donor (related or unrelated)
  - living donor transplants have been shown to have better outcomes than deceased donor transplants
  - kidney transplanted into iliac fossa, transplant renal artery anastomosed to external iliac artery of recipient
  - 1 yr renal allograft survival rates ≥90%

Complications

- #1 cause of mortality in transplanted patients is cardiovascular disease
- de novo GN (usually membranous)
- new-onset DM (often due to prednisone and calcineurin inhibitors, especially tacrolimus)
- graft rejection
  - acute rejection: graft site tenderness, rise in Cr, oliguria, ± fever, although symptoms are uncommon
  - early allograft damage caused by episodes of acute rejection and acute peritransplant injuries
  - transplant glomerulopathy from antibody injury causes nephrotic proteinuria
  - cyclosporine or tacrolimus nephrotoxicity (see Small Vessel Disease, NP29)
  - BK virus (polyoma virus) nephropathy can result from over-immunosuppression and lead to graft loss
  - leading causes of late allograft loss: interstitial fibrosis/tubular atrophy (IFTA) and death with functioning graft
  - depends on immunologic and nonimmunologic factors (HTN, hyperlipidemia, age of donor, quality of graft, new onset DM)
  - infections (CMV, PJP and other opportunistic infections usually occur between 1 and 6 mo post-transplant)
  - malignancy (skin cancer, Kaposi’s sarcoma, non-Hodgkin’s lymphoma)

### Approach to the Neurological Complaint

**Lesion Localization**

- **cortical**
  - contralateral paresis (with differential effect on face and arm vs. leg)
  - UMN injury (hyperreflexia, Babinski sign, spasticity, no atrophy, pyramidal pattern of weakness)
  - cortical sensory loss (hemisensory loss, position sense, two-point discrimination, graphesthesia, stereognosis)
  - dominant hemisphere (aphasia, alexia, agraphia, acalculia, left-right disorientation)
  - non-dominant hemisphere (hemineglect, dysprosody, anosmia, constructional apraxia)
  - homonymous hemianopia, quadrantanopia
  - gaze deviation
  - seizure
  - agnosia (visual, auditory)
  - apraxia
  - alien hand syndrome

- **subcortical**
  - internal capsule: contralateral paresis with equal face, arm, leg involvement without sensory/cortical deficits; contralateral dysmetria/clumsiness and leg paresis
  - basal ganglia: pill-rolling tremor, bradykinesia, festinating gait, hemiballismus, chorea, dystonic posture
  - thalamus: dense sensory loss, contralateral severe pain

- **brainstem (bulbar)**
  - crossed hemiplegia or sensory loss (i.e. ipsilateral face, contralateral body)
  - ipsilateral cerebellar (dysmetria, rapid alternating movements, tandem gait)
  - nystagmus toward lesion, diplopia, INO (impaired adduction on contralateral gaze)
  - dysphagia, dysarthria
  - hearing loss, vertigo

- **cerebellum**
  - ipsilateral ataxia (unsteadiness, incoordination)
  - dysmetria, intention tremor
  - dysdiadochokinesis
  - wide-based gait, truncal titubation (staggering, reeling, lurching)
  - scanning speech (explosive speech with noticeable pauses and accentuated syllables)
  - nystagmus, distorted smooth pursuit, oscillopsia

- **spinal cord**
  - bilateral motor and/or sensory deficits below the lesion without facial involvement
  - ataxia, sensory level (sharp line below which there is decreased sensation); suspended "cape-like" sensory level
  - LMN signs (flaccid paresis, hypotonia, hyporeflexia, atrophy, fasciculations) at level of lesion; UMN signs below lesion (marked spasticity and Babinski)
  - bowel, bladder, sexual dysfunction
  - saddle anesthesia
  - ataxia

- **nerve root**
  - multiple peripheral nerve involvement
  - myotomal/dermatomal deficits
  - back/neck pain radiating to leg/arm
• peripheral nerve
  ■ distal “stocking-glove distribution” sensory loss
  ■ LMN signs (hypotonia, hyporeflexia, fasciculations, atrophy)
• neuromuscular junction
  ■ fluctuating/fatiguable symptoms
  ■ facial and limb weakness
  ■ dysphonia, dysarthria
  ■ ophthalmoparesis (diplopia), ptosis
• muscle
  ■ symmetric proximal weakness (climbing stairs, getting up from chair) without sensory deficits
  ■ muscle tenderness
  ■ muscle atrophy

The Neurological Exam

General Exam and Mental Status

• vitals: pulse (especially rhythm), BP, RR, temperature
• H&N: meningismus, head injury/bruises (signs of basal skull fracture: Battle’s sign, raccoon eyes, hemotympanum, CSF rhinorrhea/otorrhea), tongue biting
• CVS: carotid bruits, heart murmurs
• mental status: orientation (person, place, time), LOC (GCS) (see Emergency Medicine, ER4)
  ■ GCS/15 – Motor/6, Verbal/5 (T= intubated), Eyes/4
• cognition
  ■ Folstein MMSE – /30 (note: dementia is a clinical diagnosis and is not diagnosed by cognitive testing)
  ■ MoCA – /30 (≥26 is considered normal)
  ■ frontal lobe testing (for perseveration – i.e. go/no-go test)
  ■ clock drawing

Screening Neurologic Exam

• Mental status: orientation (person, place, time), obeys commands, GCS
• Head and neck: examine for lacerations, contusions, deformities, signs of basal skull fracture, flex neck for meningismus if c-spine injury has been ruled out
• Cranial nerve exam: visual fields ± fundoscopy, pupil size and reactivity, extraocular movements, facial strength, hearing to finger rub
• Motor: tone, power in deltoids, triceps, wrist extensors, hand interossei, hamstrings, ankle dorsiflexors, pronator drift
• Coordination: finger tapping, finger-to-nose, heel knee shin
• Gait: tandem gait, heel walking
• Reflexes: plantar, biceps, triceps, patellar
• Sensation: all 4 limbs, including double simultaneous stimulation, vibration sense

Cranial Nerve Exam

### Tests

- **EMG**: Denervated and reinnervated, signs of demyelination ≤ anomalous loss, decremental response, jitter on single fibre EMG, small, short motor potentials
- **NCS**: Normal
- **Muscle Enzyme**: Normal

* *e.g. orthostatic hypotension, anhidrosis, visual blurring, urinary hesitancy or incontinence, constipation, erectile dysfunction*
Table 4. Approach to Strength Testing of Radiculopathies vs. Peripheral Neuropathies

How to use this table: For each nerve root, learn two (or more) peripheral nerves (and their associated muscles/movements). In radiculopathies, all associated peripheral nerves (and their movements) will be impaired, whereas in peripheral neuropathies, only one of the nerves (and its movement) will be impaired, sparing the other nerve. Particularly useful peripheral nerve “pairs” are bolded for emphasis.

Sensory Exam

- primary sensation
  - spinothalamic tract: crude touch, pain, temperature
  - dorsal column-medial lemniscus pathway: fine touch, vibration, proprioception
- cortical sensation
  - graphesthesia, stereognosis, extinction, 2 point discrimination

Coordination Exam and Gait

- coordination exam
  - finger-to-nose, heel-to-shin, knee taps, rapid alternating movements
- stance and gait
  - Romberg test
  - pull test or push and release test for postural instability
  - gait: antalgic, hemiplegic, ataxic, apraxic (or apraxia-like – not necessarily true apraxia), Parkinsonian gait, foot drop, broad-based
  - tandem gait (heel-to-toe test)
Basic Anatomy Review

Figure 1. Brainstem (axial view)

Figure 2. Brainstem (posterior view)
Figure 3. Discriminative touch pathway (dorsal column) from body

Figure 4. Spinothalamic tract from body

Figure 5. Discriminative touch pathway (dorsal column) from face

Figure 6. Spinothalamic tract pathway from face

Figure 7. Corticospinal motor pathway
Figure 8. Sympathetic and parasympathetic pathway

Sympathetic
- Pupil (Dilation, Constriction)
- Lacrimal and salivary glands (Modulate secretion)
- Submaxillary g. (salivation)
- Otic g. (parotid secretion)
- Superior cervical ganglion
- Bronchodilation
- Coronary arteries and heart rate (Vasodilation, acceleration)
- Glycogen utilization
- Adrenal medulla
- Bladder (Inhibit constriction)
- Reproductive system
- Piloerector
- Skin
- Vasoconstriction

Parasympathetic
- Pupil (Dilation, Constriction)
- Lacrimal and salivary glands (Modulate secretion)
- Pterygopalatine g. (lacrimation)
- Modulate secretion
- Otic g. (parotid secretion)
- Bronchodilation
- Coronary arteries and heart rate (Vasoconstriction, deceleration)
- Glycogen utilization
- Liver
- Bile secretion
- Gl tract
- GI tract
- Inhibit motility and enzyme secretion
- Stimulate motility and enzyme secretion
- Reproductive system
- Ejaculation
- Erection

Figure 9 Dermatome map

Myotomes
- C5 – Shoulder abduction/elbow flexion
- C6 – Wrist extenders
- C7 – Elbow extension
- C8 – Finger flexion
- T1 – Finger abduction
- T2–9 – Intercostal (abdominal reflexes)
- T9-10 – Upper abdominals
- T11–12 – Lower abdominals
- L1 – Hip flexion
- L2 – Hip adduction
- L4 – Knee extension and ankle dorsiflexion
- L5 – Ankle dorsiflexion and big toe extension
- S1 – Plantarflexion
Lumbar Puncture

**Indications**
- diagnostic: CNS infection (meningitis, encephalitis), inflammatory disorder (MS, Guillain-Barré, vasculitis), subarachnoid hemorrhage (if CT negative), CNS neoplasm (neoplastic meningitis)
- therapeutic: to administer anesthesia, chemotherapy, contrast media; to decrease ICP (pseudotumour cerebri, NPH)

**Contraindications**
- mass lesion causing increased ICP, could lead to cerebral herniation; CT first if suspect mass lesion
- infection over LP site/suspected epidural abscess
- low platelets (<50,000) or treatment with anticoagulation (high INR or aPTT)
- uncooperative patient

**Complications**
- tonsillar herniation (rare)
- SDH (rare)
- transient 6th nerve palsy (rare)
- post-LP headache (5-40%): worse when upright, better sitting; generally onset within 24 h
  - prevention: smaller gauge (i.e. 22) needle, reinsert stylet prior to needle removal, blunt-ended needle
  - symptomatic treatment: caffeine and sodium benzoate injection
  - corrective treatment: blood patch (autologous)

**LP Tubes**
- **tube #1**: cell count and differential: RBCs, WBCs, and differential
  - xanthochromia (yellow bilirubin pigmentation implies recent bleed into CSF, diagnostic of SAH)
- **tube #2**: chemistry: glucose (compare to serum glucose) and protein
- **tube #3**: microbiology: Gram stain and C&S
  - specific tests depending on clinical situation/suspicion
    - viral: PCR for herpes simplex virus (HSV) and other viruses
    - bacterial: polysaccharide antigens of *H. influenzae*, *N. meningitidis*, *S. pneumoniae*
    - fungal: cryptococcal antigen, culture
    - TB: acid-fast stain, TB culture, TB PCR
- **tube #4**: cytology: for evidence of malignant cells
- **tube #5**: cell count: compare RBC count to that of tube #1
  - note: tube 4 or 5 can be sent for repeat cell count

</tbody>
</table>

**Approach to Common Presentations**

**Weakness**

**Approach**
- **mode of onset**: abrupt (vascular, toxic, metabolic), subacute (neoplastic, infective, inflammatory), insidious (hereditary, degenerative, endocrine, neoplastic)
- **course**: worse at onset (vascular), progressive (neoplastic, degenerative, infective), episodic (vascular, inflammatory), activity dependent (NMJ, muscular)
- **pattern**: objective vs. subjective, generalized vs. localized, asymmetric vs. symmetric, proximal vs. distal, UMN vs. LMN, peripheral vs. myotomal
- **associated symptoms**: sensory, cortical, autonomic, spinal (i.e. bowel/bladder dysfunction), signs/symptoms specific to various etiologies
- **history**: family history, developmental history, medications, risk factors, recent/preceding exposures
- **investigations for LMN**: NCS/EMG
- **investigations for UMN**: imaging (brain and/or spinal cord)
Differential Diagnosis
• objective muscle weakness; also, differentiate between true muscle weakness vs. fatigue
  • generalized
    • myopathy (proximal > distal weakness)
      – endocrine: hypothyroidism, hyperthyroidism, Cushing's syndrome
      – rheumatologic: polymyositis, vasculitis
      – infectious: HIV, CMV, influenza
      – other: collagen vascular disorders, steroids, statins, alcohol, electrolyte disorders
    • NMJ (MG, botulism, LEMS, organophosphate poisoning)
    • cachexia
  • localized
    • UMN (vasculitis, abscess, brain tumour, vitamin B12 deficiency, MS, stroke)
    • radicular pain (i.e. nerve root)
    • anterior horn cell (spinal muscular atrophy, ALS, polio, paraneoplastic, lead toxicity)
    • peripheral neuropathy (peroneal muscle atrophy, GBS, leprosy, amyloid, myeloma, DM, lead toxicity)
• no objective muscle weakness
  • chronic illness (cardiac, pulmonary, anemia, infection, malignancy)
  • depression, deconditioning

Numbness/Altered Sensation
Approach
• positive sensory symptoms: paresthesia/dysesthesia = tingling, pins and needles, prickling, burning, stabbing
• negative sensory symptoms: hypoesthesia/anesthesia = numbness, reduction/absence of feeling
• determine distribution of sensory loss:
  • nerve root vs. peripheral nerve
  • symmetric stocking-glove pattern (indicative of distal symmetric polyneuropathy)
  • dissociated sensory loss: dorsal column (fine touch, proprioception, vibration) vs. spinothalamic tract (pain and temperature)
• investigations: NCS, blood glucose, vitamin B12 levels, imaging based on associated findings

Differentia Diagnosis
• cerebral: stroke, demyelination, tumour
  • associated symptoms: hemiplegia, aphasia, apraxia
• brainstem: stroke, demyelination, tumour
  • associated symptoms: diplopia, vertigo, dysarthria, dysphagia
• spinal cord/radiculopathy: cord infarction, tumour, MS, syringomyelia, vitamin B12 deficiency, disc lesion
  • associated symptoms: back/neck pain, weakness (paraparesis or Brown-Séquard pattern)
• neuropathy: focal compressive neuropathy (based on location and distribution), DM, uremia, vasculitis, vitamin B12 deficiency, HIV, Lyme disease, alcohol, paraneoplastic, amyloid

Gait Disturbance
Approach
1. Characterization of the gait disturbance
  • posture, stride length, width between feet, height of step, stability of pelvis, symmetry, arm swing, difficulty turning, tremor, elaborate/inconsistent movements, standing from sitting
2. Identification of accompanying neurologic signs
  • full neurological exam required (diagnosis often can be made by P/E alone)
3. Identify red flags
  • sudden onset, cerebellar ataxia, paresis (hemiparesis, para- or quadri-), bowel/bladder incontinence
4. Workup
  • based on etiology – requires blood work, neuroimaging, and urgent neurologist referral
### Cranial Nerve Deficits

#### CN I: Olfactory Nerve

**Clinical Features**
- anosmia associated with a loss of taste

**Differential Diagnosis**
- **nasal**: physical obstruction
  - heavy smoking, chronic rhinitis, sinusitis, neoplasms, septal deformity, choanal atresia, vestibular stenosis, foreign body
- **olfactory neuroepithelial**: destruction of receptors or their axon filaments
  - influenza, herpes simplex, interferon treatment of hepatitis C virus, atrophic rhinitis (leprosy)
- **central**: lesion of olfactory pathway
  - Kallmann syndrome, albinism, head injury, cranial surgery, SAH, chronic meningeal inflammation, meningoïd, aneurysm, PD, stroke, MS
- **endocrine/metabolic**
  - DM, adrenal hypo/hyperfunction, pseudohypoparathyroidism, hypothyroidism, renal/liver failure, vitamin deficiency

If anosmia is not associated with loss of taste, consider malingering.

#### CN II: Optic Nerve

- see *Neuro-Ophthalmology*, N14

#### CN III: Oculomotor Nerve

**Clinical Features**
- ptosis, resting eye position is “down and out” (depressed and abducted), pupil dilated (mydriasis)
- vertical and horizontal diplopia; paralysis of adduction, elevation, and depression

**Differential Diagnosis**
- **PComm aneurysm**: early mydriasis, then CN III palsy
- **cavernous sinus** (internal carotid aneurysm, meningoïd, sinus thrombosis): associated with deficits in other CNs near the cavernous sinus
- **midbrain lesion**: complete unilateral CN III palsy with bilateral weakness of the superior rectus and ptosis with contralateral pyramidal signs ± mydriasis
- **orbital lesion**: associated with optic neuropathy, chemosis, proptosis
- **other** inflammatory, infection, neoplasia, uncal herniation, trauma

Lesions involving the cavernous sinus can lead to cranial nerve palsies of III, IV, VI, V1, and V2 as well as orbital pain and proptosis.

Lesion-isolating vs. pupil-sparing approach: mydriasis may be caused by ischemia or compression.”

Pupillary constrictor fibres run along outside of nerve, whereas vasculature is contained within nerve. For CN III palsy with a reactive pupil, always think ischemic cause (“pupil sparing”). For CN III palsy with mydriasis, think compressive lesion.

Kallmann syndrome is a congenital disorder of anosmia and hypogonadotropic hypogonadism.
**CN IV: Trochlear Nerve**

**Clinical Features**
- vertical and torsional diplopia; defect of intorsion and depression
- patient may complain of difficulty going down stairs or reading

**Differential Diagnosis**
- common: ischemic (DM, HTN), idiopathic, trauma (TBI or surgical), congenital
- other: cavernous sinus lesion, superior orbital fissure (tumour, granuloma)

**CN V: Trigeminal Nerve**

**Clinical Features**
- ipsilateral loss of facial sensation and corneal reflex, weakness of muscles of mastication (V3 only) with pterygoid deviation towards the side of the lesion

**Differential Diagnosis**
- brainstem: ischemia, tumour, syringobulbia, demyelination
- peripheral: tumour, aneurysm, chronic meningitis, me atastic infiltration of nerve
- trigeminal ganglion: acoustic neuroma, meningioma, fracture of middle fossa
- cavernous sinus: carotid aneurysm, meningioma, sinus thrombosis
- trauma
- note: other CN V lesions that cause facial pain = trigeminal neuralgia, herpes zoster

**CN VI: Abducens Nerve**

**Clinical Features**
- resting inward deviation (esotropia)
- horizontal diplopia; defect of lateral gaze

**Differential Diagnosis**
- pons (infarction, hemorrhage, demyelination, tumour): associated with facial weakness and contralateral pyramidal signs
- tentorial orifice (compression, meningioma, trauma): false localizing sign of increased ICP
- cavernous sinus: carotid aneurysm, meningioma, sinus thrombosis
- ischemia of CN VI: DM, temporal arteritis, HTN, atherosclerosis
- congenital: Duane's syndrome

**CN VII: Facial Nerve**

**Clinical Features**
- LMN lesion: ipsilateral facial weakness (facial droop, flattening of forehead, inability to close eyes, flattening of nasolabial fold)
- UMN lesion: contralateral facial weakness with forehead sparing (due to bilateral frontalis innervation)
- impaired lacrimation, decreased salivation, numbness behind auricle, hyperacusis, taste dysfunction of anterior 2/3 of tongue

**Differential Diagnosis**
- idiopathic = Bell's palsy, 80-90% of cases (see Otolaryngology, OT22)
- most often related to HSV, but other viruses may be implicated (CMV, herpes zoster, EBV)
- other: temporal bone fracture, EBV, Ramsay Hunt (VZV), otitis media/mastoiditis, sarcoidosis, DM mononeuropathy, parotid gland disease, Lyme meningitis, HIV

![Figure 11. Cavernous sinus (coronal view)](image-url)
**CN VIII: Vestibulocochlear Nerve**

- see Otolaryngology, OT14

**CN IX: Glossopharyngeal Nerve**

**Clinical Features**
- unilateral lesion is rare
- taste dysfunction in posterior 1/3 of tongue
- absent gag reflex and dysphagia

**Disorders**
- glossopharyngeal neuralgia: sharp paroxysmal pain of posterior pharynx radiating to ear, triggered by swallowing
  - treated with carbamazepine or surgical ablation of CN IX

**CN X: Vagus Nerve**

**Clinical Features**
- oropharyngeal dysphagia (transfer dysphagia) due to palatal and pharyngeal weakness
  - neuromuscular causes of dysphagia
    - CNS: stroke, cerebral palsy, tumour, trauma, PD, AD, MS
    - CN: DM, laryngeal nerve palsy, polio, ALS
    - myopathic/NMJ: dermatomyositis, polymyositis, MG, sarcoidosis
  - other causes of dysphagia: see Gastroenterology G8
- dysarthria: inability to produce understandable speech due to impaired phonation and/or resonance

**CN XI: Accessory Nerve**

**Clinical Features**
- LMN lesion: paralysis of ipsilateral trapezius and sternocleidomastoid (ipsilateral shoulder drop, weakness on turning head to contralateral side)
- UMN lesion: paralysis of ipsilateral sternocleidomastoid and contralateral trapezius

**CN XII: Hypoglossal Nerve**

**Clinical Features**
- LMN lesion: tongue deviation towards lesion; ipsilateral tongue atrophy and fasciculations (if chronic)
- UMN lesion: tongue deviation away from lesion; absence of atrophy and fasciculations
**Neuro-Ophthalmology**

**Optic Neuritis**
- See Optic Disc Edema, Multiple Sclerosis, N52

**Anterior Ischemic Optic Neuropathy (AION)**
- See Optic Disc Edema
- Non-arteritic (NAION): due to atherosclerosis
- Arteritic (AAION): due to giant cell arteritis (see Rheumatology, RH20)

**Amaurosis Fugax**
- See Ophthalmology, OP35 and Stroke, N48

**Optic Disc Edema**

**Optic Disc Atrophy**
- **Etiologies**: glaucoma, AION, compressive tumour, optic neuritis, Leber’s hereditary optic neuropathy, congenital
- **Presentation**: disc pallor, low visual acuity, peripheral vision defect, decreased colour vision
- **Treatment**: none (irreversible), aim to prevent

NAION can be caused by use of sildenafil (Viagra®) in rare cases.
If you suspect the diagnosis of giant cell arteritis do not wait for biopsy results, begin treatment immediately.

NAION can be caused by use of sildenafil (Viagra®) in rare cases.
Abnormalities of Visual Field

Figure 13 Characteristic visual field defects with lesions along the visual pathway

Abnormalities of Eye Movements

Disorders of Gaze

Pathophysiology
- horizontal gaze: FEF → contralateral PPRF (midbrain/pons) → eyes saccade away from FEF
- vertical gaze: cortex → rostral interstitial nucleus in the MLF (midbrain)

Clinical Features
- unilateral lesion in one FEF → eyes deviate toward the side of the lesion
  - can be overcome with doll’s eye maneuver
- unilateral lesion in the PPRF → eyes deviate away from the lesion
  - cannot be overcome with doll’s eye maneuver if CN VI nucleus lesion as well
- seizure involving a FEF: eyes deviate away from the focus

Etiology
- common: infarcts (frontal or brainstem), MS, tumours

Internuclear Ophthalmoplegia

Pathophysiology
- results from a lesion in MLF which disrupts coordination between CN VI nucleus in pons and the contralateral CN III nucleus in midbrain → disrupts conjugate horizontal gaze

Clinical Features
- horizontal diplopia on lateral gaze, oscillopsia
- gaze away from the side of the lesion: ipsilateral adduction defect and contralateral abduction nystagmus
- cannot be overcome by caloric testing
- accommodation reflex intact
- may be bilateral (especially in MS)

Etiology
- common: MS, brainstem infarct

Investigations
- MRI

Figure 14. Internuclear ophthalmoplegia
## Abnormalities of Eye Movements

### Diplopia

**Etiology – Monocular**
- mostly due to relatively benign optical problems (refractive error, cataract) or functional

**Etiology – Binocular (due to ocular misalignment)**
- muscle: Graves' ophthalmopathy, EOM restriction/entrapment
- neuromuscular junction: MG (see Myasthenia Gravis, N38)
- cranial nerve palsy (see Cranial Nerve Deficits, N11)
- INO (see Internuclear Ophthalmoplegia, N15)
- other
  - orbital trauma (orbital floor fracture), tumour, infection, inflammation
  - Miller-Fisher variant of GBS
  - Wernicke's encephalopathy
  - leptomeningeal disease

### Approach to Diplopia
- monocular (diplopia when one eye open) vs. binocular (diplopia when both eyes open)
- horizontal vs. vertical vs. oblique diplopia
- direction of gaze that exacerbates diplopia
- corrective head movements

**Workup**
- may observe isolated 4th or 6th nerve palsy for a few weeks, but workup if persistent or other symptoms develop
- indications for neuroimaging
  - bilateral or multiple nerve involvement
  - severe sudden onset headache (rule out aneurysm)

### Nystagmus

**Definition**: rapid, involuntary, small amplitude movements of the eyes that are rhythmic in nature
- direction of nystagmus is labelled by the rapid component of the eye movement
- can be categorized by movement type (pendular, jerking, rotatory, coarse) or as physiological vs. pathological

### Table 8. Nystagmus Features

### Abnormalities of Pupils

- see Ophthalmology, OP28
Nutritional Deficiencies and Toxic Injuries

- Sufficient nutritional intake is required for optimal nervous system functioning; deficiencies in the following key nutrients, among others, may impair central and peripheral nervous system function (potential neurological symptoms are provided).

<table>

*IM = intramuscular; IV = intravenous

- It is also important to consider occupational neurotoxic syndromes secondary to exposure to pesticides, solvents, and metals. Encephalopathy, extrapyramidal features, neurodegenerative diseases, and peripheral neuropathy are commonly encountered. Onset and progression of neurological diseases should be temporally related to neurotoxin exposure. Main toxins associated with neurotoxicity are listed below.

Neurologic Complications due to Toxic Injuries Related to Bariatric Surgery

- Deficiencies of both fat- and water-soluble vitamins may occur following malabsorptive bariatric surgery.
- Patients who have undergone malabsorptive surgery should be monitored for late metabolic complications and neurological manifestations.
Seizure Disorders and Epilepsy

Definitions

**Seizure**: transient occurrence of signs and/or symptoms due to abnormal excessive or synchronous neuronal brain activity

- can be symptom of acute insult to the brain such as: alcohol and illicit drug use/withdrawal, brain injury/abnormality (tumour, trauma, vascular), CNS infection, fever (children), metabolic (hypoglycemia, electrolyte abnormalities, liver/renal failure), medications, or be a manifestation of epilepsy

**Epilepsy**: disorder of the brain characterized by an enduring predisposition to generate epileptic seizures, and, by the neurobiologic, cognitive, psychological, and social consequences of this condition. The definition of epilepsy requires the occurrence of at least one epileptic seizure

- etiologies: genetic, structural (e.g. prior stroke, tumour, meningoencephalitis, perinatal insult, vascular malformation, malformation of cortical development neurodegenerative), or unknown

Classification

**Clinical Features**

- **focal (partial) seizures**
  - focal can secondarily generalize, or focal (simple) → focal with impaired awareness (complex) → generalized seizures
  - focal with intact awareness (simple partial)
    - motor: postural, phonatory, forceful turning of eyes and/or head, focal muscle rigidity/jerking ± Jacksonian march (spreading to adjacent muscle groups)
    - sensory: unusual sensations affecting vision, hearing, smell, taste, or touch
    - autonomic: epigastric discomfort, pallor, sweating, flushing, piloerection, pupillary dilatation
    - psychiatric: symptoms rarely occur without impairment of consciousness and are more commonly complex partial
  - focal with impaired awareness (complex partial)
    - patient may appear to be awake but with impairment of awareness
    - classic complex seizure is characterized by automatisms such as chewing, swallowing, lip smacking, scratching, fumbling, running, disrobing, and other stereotypic movements
    - other forms: dysphasic, dysemic (déjà vu), cognitive (disorientation of time sense), affective (fear, anger), illusions, structured hallucinations (music, scenes, taste, smells), epigastric fullness

- **generalized seizures**
  - absence (petit mal): usually seen in children, unresponsive for 5-10 s with arrest of activity, staring, blinking or eye-rolling, no post-ictal confusion; 3 Hz spike and slow wave activity on EEG
  - clonic: repetitive rhythmic jerking movements
  - tonic: muscle rigidity in flexion or extension
  - tonic-clonic (grand mal)
    - may have prodrome of unease or irritability hours to days before the episode (aura)
    - tonic ictal phase: muscle rigidity
    - clonic ictal phase: repetitive violent jerking of face and limbs, tongue biting, cyanosis, frothing, incontinence
    - post-ictal phase: flaccid limbs, extensor plantar reflexes, headache, confusion, aching muscles, sore tongue, amnesia, elevated serum CK lasting hours; may have focal paralysis (Todd's paralysis)
  - myoclonic: sporadic contractions localized to muscle groups of one or more extremities
  - atonic: loss of muscle tone leading to drop attack

Stroke is the most common cause of late-onset (>50 yr) seizures, accounting for 50-80% of cases

Seizures and Dementia

Neurodegenerative diseases can underlie seizures; conversely, seizures can be a cause of dementia

Temporal lobe epilepsy is suggested by an aura of fear, olfactory or gustatory hallucinations, and visceral or déjà vu sensations

Frontoparietal cortex seizures are suggested by contralateral focal sensory or motor phenomena
**Table 11. Classic Factors Differentiating Seizure, Syncope and Pseudoseizure**

<td>Usually abnormal; ± interictal discharges</td>
<td>Normal</td>
<td>Normal</td>
</tr>
</tbody>
</table>

*Pseudoseizures do not rule out seizures (not uncommon to have both)*

- alcoholic withdrawal seizures may occur up to 2 days from the last exposure to alcohol (see Emergency Medicine, ER54)

**Investigations**
- CBC, electrolytes, fasting blood glucose, Ca²⁺, Mg²⁺, ESR, Cr, liver enzymes, CK, prolactin
- also consider toxicology screening, EtOH level, AED level (if applicable)
- CT/MRI (if new seizure without identified cause or known seizure history with new neurologic signs/symptoms)
- LP (if fever or meningismus)
- EEG

**Treatment**
- avoid precipitating factors
- indications for antiepileptic drugs (AED): EEG with epileptiform activity, remote symptomatic cause (organic brain disease, prior head injury or CNS infection), abnormal neurologic examination or findings on neuroimaging, nocturnal seizure
- psychosocial issues: stigma of seizures, education of patient and family, status of driver’s license, pregnancy issues
- safety issues: driving, operating heavy machinery, bathing, swimming alone
- refer for evaluation for possible surgical treatment if focal and refractory

**Status Epilepticus**
- definition: unremitting seizure or successive seizures without return to a baseline state of greater than 5 min
- complications: anoxia, cerebral ischemia and cerebral edema, MI, arrhythmias, cardiac arrest, rhabdomyolysis and renal failure, aspiration pneumonia/pneumonitis, death (20%)
- initial measures: ABCs, vitals, monitors, capillary glucose (STAT), ECG, nasal O₂, IV NS, IV glucose, IV thiamine, ABGs (if respiratory distress/cyanotic)
- blood work: electrolytes, Ca²⁺, Mg²⁺, PO₄³⁻, glucose, CBC, toxicology screen, EtOH level, AED levels
- focused history: onset, past history of seizures, drug and alcohol ingestion, past medical history, associated symptoms, witnesses/collateral history
- physical exam (once seizures controlled): LOC, vitals, HEENT (nuchal rigidity, head trauma, tongue biting, papilledema), complete neurological exam, signs of neurometabolic disorders, decreased breath sounds, cardiac murmurs or arrhythmias, urinary incontinence, MSK exam (rule out injuries)
- post-treatment stabilization: CT head, EEG, Foley catheter to monitor urine output, urine toxicology screen, monitor for rhabdomyolysis, and IV fluids to maintain normal cerebral perfusion pressure

**Antiepileptic Drugs**
- focal and more generalized seizures
  - valproate (Depakene®), lamotrigine (Lamictal®), levetiracetam (Keppra®), topiramate (Topamax®), phenobarbital (Phenobarb®), primidone, zonisamide, rufinamide (Ranzel®), felbamate, benzodiazepines
- primarily focal seizures (± 2° generalization)
  - carbamazepine (Tegretol®), phenytoin (Dilantin®), gabapentin (Neurontin®), lacosamide (Vimpat®), oxcarbazepine (Trileptal®), eslicarbazepine acetate (Aptiom®), pregabalin (Lyrica®), tiagabine (Gabitril®), vigabatrin (Sabril®)
- absence seizure: ethosuximide (Zarontin®)

**DDx of Convulsions**
- Syncope, pseudoseizure, hyperventilation, panic disorder, TIA, hypoglycemia, movement disorder, alcoholic blackouts, migraines (confusional, vertebrobasilar), narcolepsy (cataplexy)

Note that frontal seizures (rare) can look like a pseudoseizure due to odd motor activity that may occur

By law, the Ministry of Transportation in most provinces must be contacted for all patients who have had a seizure; patients will have their license suspended until seizure free for 6 mo; commercial drivers face a longer wait

EEG findings suggestive of epilepsy: abnormal spikes, polyspike discharges, spike-wave complexes

20-59% of first EEG are positive in epilepsy; 59-92% of epilepsy is picked up with repeated EEGs; normal interictal EEGs do not rule out epilepsy

**Medical Emergency: Status epilepticus**
- can cause irreversible brain damage without treatment

The most common causes of status epilepticus are failure to take AEDs and first presentation of epilepsy
- Status epilepticus as a result of EtOH withdrawal is rare, despite it being a very common cause of seizures

Rule out non-convulsive status epilepticus in any patient who is ≤ unconscious >20 min post-ictal; order a stat EEG if unsure

Complex partial status epilepticus can resemble schizophrenia or psychotic depression
**Behavioural Neurology**

- see Psychiatry, PS19

**Mild Neurocognitive Disorder (Mild Cognitive Impairment)**

**Definition**
- cognitive impairment not meeting criteria of Major Neurocognitive Disorder
- measurable deficit in at least one cognitive domain reported by patient or others without impairment in ADLs
- amnestic (precursor to AD) vs. non-amnestic

**Epidemiology**
- mild NCD: 2-10% at age 65 yr and 5-25% by age 85 yr

**Risk Factors**
- vascular: hypertension, diabetes mellitus, obesity, cardiac disease, apolipoprotein E epsilon 4 genotype

**Clinical Features**
- cognitive impairment
  - particularly in amnestic subtype
  - important to ascertain that memory complaints represent change from baseline
  - patients with mild NCD are often troubled by memory symptoms in comparison to patients with dementia
- neuropsychiatric symptoms
  - depression (50%), irritability, anxiety, aggression, and apathy

**Investigations**
- establish a baseline for follow-up
- clinical interview with patient and caregivers is the cornerstone of mild NCD evaluation
- neuropsychological testing
  - MMSE or MoCA; should not be used in isolation
  - if abnormal, follow-up in one year to monitor cognitive and functional decline
- neuroimaging
  - role uncertain
  - most advocate for a non-contrast brain CT to evaluate for structural abnormalities (CVD, SDH, NPH, or mass lesion)
- other testing
  - exclude treatable conditions and underlying psychiatric conditions

**Treatment**
- watch and wait
- no evidence for cholinesterase inhibitors, anti-inflammatory agents, vascular risk factor modification, exercise, cognitive interventions

**Prognosis**
- 10% progress to major NCD per yr
- typically progress to major NCD over a period of 2-3 yr

**Major Neurocognitive Disorder (formerly Dementia)**

- see Psychiatry, PS20 and Geriatric Medicine, GM4

**Definition**
- an acquired, generalized, and (usually) progressive impairment of cognitive function associated with impairments in ADLs/iADLs (i.e. shopping, food preparation, finances, medication management)
- diagnosis of major NCD requires presence of significant cognitive decline from a previous level of performance in one or more cognitive domains (complex attention, executive function, learning and memory, language, perceptual-motor, or social cognition) based on:
  A) concern of the individual or a knowledgeable informant AND
  B) a substantial impairment in cognitive performance either documented by standardized neuropsychological testing, or quantified clinical assessment
- see Psychiatry, PS20 for DSM-5 diagnostic criteria
- in comparison, mild NCD does not affect ADLs
  - mild NCD represents an intermediate stage between major NCD and normal aging

**Epidemiology**
- major NCD: 1-2% at age 65 yr and reaching as high as 30% by age 85 yr
- note
  - major NCD due to Alzheimer’s disease is uncommon before age 60 yr
  - major NCD due to frontotemporal lobar degeneration has an earlier onset and represents a progressively smaller fraction of all NCDs with increasing age
Etiology
- see Table 13 for selected causes of major NCD
- reversible causes: alcohol (intoxication or withdrawal, Wernicke's encephalopathy), medication (benzodiazepines, anticholinergics), heavy metal toxicity, hepatic or renal failure, B12 deficiency, glucose, cortisol, thyroid dysfunction, normal pressure hydrocephalus (NPH), depression (pseudodementia), intracranial tumour, SDH, hypercalcemia (secondary to elevated PTH)
- must rule out delirium

History
- "geriatric giants"
  - confusion/incontinence/falls
  - memory and safety (wandering, leaving doors unlocked, leaving stove on, losing objects, driving)
  - behavioural (mood, anxiety, psychosis, suicidal ideation, personality changes, aggression)
  - polypharmacy and compliance (sedative hypnotics, antipsychotics, antidepressants, anticholinergics)
- ADLs and IADLs
- cardiovascular, endocrine, neoplastic, renal ROS, head trauma history
- alcohol, smoking
- collateral history

Physical Exam
- blood pressure
- hearing and vision
- neurological exam with attention to signs of parkinsonism, UMN findings
- general physical exam with focus on CVD, patient-specific risk factors and history
- MMSE or MoCA, clock drawing, frontal lobe testing (go/no-go, word lists, similarities, proverb)

Investigations
- rule out reversible causes
  - CBC (note MCV for evidence of alcohol use and B12 deficiency), glucose, TSH, B12, RBC folate
electrolytes, LFTs, renal function, lipids, serum calcium
- CT head, MRI as indicated, SPECT (optional)
- as clinically indicated: VDRL, HIV, ANA, anti-dsDNA, ANCA, ceruloplasmin, copper, cortisol, toxicology, heavy metals
- issues to consider
  - failure to cope, fitness to drive, caregiver capacity and wellbeing, power of attorney, legal will, advanced medical directives, patient and caregiver safety

Major or Mild NCD due to Alzheimer’s Disease

- see Psychiatry, PS20

Definition
- beyond criterion for NCD, the core features of Alzheimer’s disease include an insidious onset and gradual progression of cognitive and behavioural symptoms
- typical presentation: amnestic
  - mild phase: impairment in memory and learning sometimes accompanied with deficits in executive function
  - moderate-severe phase visuoconstructional/perceptual-motor ability and language may also be impaired
  - social cognition tends to be preserved until late in the course of the disease
- atypical nonamnestic presentation (one of the following):
  1. aphasia: language disturbance
  2. apraxia: impaired ability to carry out motor activities despite intact motor function
  3. agnosia: failure to recognize or identify objects despite intact sensory function

Pathophysiology
- genetic factors
  - minority (<7%) of AD cases are familial (autosomal dominant)
  - 3 major genes for autosomal dominant AD have been identified:
    - amyloid precursor protein (chromosome 21), presenilin 1 (chromosome 14), presenilin 2 (chromosome 1)
    - the E4 polymorphism of apolipoprotein E (APOE) is a susceptibility genotype (E2 is protective)
    - note: APOE cannot serve as a diagnostic marker because it is only a risk factor and neither necessary nor sufficient for disease occurrence
  - pathology (although not necessarily specific for AD)
    - gross pathology
      - diffuse cortical atrophy, especially frontal, parietal, and temporal lobes (hippocampi)
microscopic pathology
- senile plaques (extracellular deposits of amyloid in the grey matter of the brain)
- loss of synapses
- neurofibrillary tangles (intracytoplasmic paired helical filaments with amyloid and hyperphosphorylated Tau protein)
- loss of cholinergic neurons in nucleus basalis of Meynert that project diffusely throughout the cortex

biochemical pathology
- 50-90% reduction in action of choline acetyltransferase

Epidemiology
- 1/12 of population 65-75 yr of age
- up to 1/3 population >85 yr of age
- very rare <65 yr of age
- accounts for 60-90% of all dementias (depending on setting and diagnostic criteria)

Risk Factors
- age is the largest risk factor
- genetic susceptibility polymorphism: apolipoprotein E4 increases risk and decreases age of onset
- other factors include: traumatic brain injury, family history; Down syndrome, low education, and vascular risk factors (e.g. smoking, HTN, hypercholesterolemia, DM)

Clinical Features
- cognitive impairment
  - memory impairment for newly acquired information (early)
  - deficits in language, abstract reasoning, and executive function
- behavioural and psychiatric manifestations (80% of those with major NCD)
  - mild NCD: major depressive disorder and/or apathy
  - major NCD: psychosis, irritability, agitation, combative ness, and wandering
- motor manifestations (late)
  - gait disturbance, dysphagia, incontinence, myoclonus, and seizures

Investigations
- perform investigations to rule out other potentially reversible causes of dementia
- EEG: usually normal, may observe generalized slowing (nonspecific)
- MRI: preferential atrophy of the hippocampi and precuneus of the parietal lobe; dilatation of lateral ventricles; widening of cortical sulci
- SPECT: hypoperfusion in temporal and parietal lobes
- PET imaging using Pittsburgh compound B (PIB) as a tracer enables imaging of beta-amyloid plaque in neuronal tissue

Treatment
- acetylcholinesterase inhibitors have been shown to slow decline in cognitive function
  - Do not prolong life expectancy but improve morbidity
  - donepezil, rivastigmine, galantamine
  - relative contraindications: bradycardia, heart block, arrhythmia, CHF, CAD, asthma, COPD, ulcers, or risk factors for ulcers and/or GI bleeding
  - galantamine is contraindicated in patients with hepatic/renal impairment
- memantine is an NMDA-receptor antagonist that has some benefits in later stage AD (i.e. when MMSE <17)
- symptomatic management
  1. pharmacologic
    - low dose neuroleptics for agitation (neuroleptics may worsen cognitive decline)
    - trazodone for sleep disturbance
    - antidepressants (SSRIs)
  2. non-pharmacologic
    - redirection
    - explore inciting factors for behaviour and modify behaviour of patient or caregiver
    - family support and day care facilities

Prognosis
- mean duration of survival after diagnosis is approximately 10 yr, reflecting the advanced age of the majority of individuals rather than the course of the disease
- death commonly results from aspiration

Cognitive Effects of Atypical Antipsychotic Medications in Patients with Alzheimer’s Disease: Outcomes from CATIE-AD
Am J Psychiatry 2011;168:831-839

Study: 421 outpatients with Alzheimer’s disease and psychosis or agitation/dissease behaviour were randomized to receive olanzapine, quetiapine, risperidone, or placebo in a multicentre double-blind RCT. MMSE and Alzheimer’s Disease Assessment Scale (ADAS) scores were measured at 36 wk.

Results: Patients receiving atypical antipsychotics exhibited a faster rate of cognitive decline as measured by MMSE scores (-0.067/wk vs. -0.007/wk). They also had a significantly faster decline compared to placebo on a composite measure of ADAS, MMSE, and various other cognitive tests (-0.011/wk vs. -0.010/wk).

Conclusions: Long-term use of atypical antipsychotics for behavioural symptoms and psychosis in dementia patients is associated with greater rates of cognitive decline.
Major or Mild NCD with Lewy Bodies
(formerly Dementia with Lewy Bodies)

Definition
• A NCD characterized by progressive cognitive impairment (with early changes in complex attention and executive function) and recurrent complex visual hallucinations
• core diagnostic features
  ■ fluctuating cognition with pronounced variations in attention and alertness
  ■ recurrent visual hallucinations that are well formed and detailed
  ■ spontaneous features of parkinsonism, with onset subsequent to development of cognitive decline (rest tremor may be absent in DLB, but otherwise same classic features of Parkinson's disease)
• suggestive/supportive features
  ■ rapid eye movement (REM) sleep behaviour disorder
  ■ severe sensitivity to neuroleptic medications (rigidity, neuroleptic malignant syndrome, extrapyramidal symptoms)
  ■ repeated falls, syncope, or transient episodes of unexplained loss of consciousness
  ■ auditory or other nonvisual hallucinations, systematic delusions, and depression

Etiology and Pathogenesis
• Lewy bodies (eosinophilic cytoplasmic inclusions) found in both cortical and subcortical structures
• mixed DLB and AD pathology is common

Diagnostically Suggestive Markers
• low striatal dopamine transporter uptake on SPECT or PET
• relative preservation of medial temporal structures on CT/MRI

Epidemiology
• 0.1-5% of the general elderly population
• Lewy bodies are present in 20-35% of all dementia cases (more common in males)

Treatment
• acetylcholinesterase inhibitors (e.g. donepezil)

Prognosis
• average duration of survival 5-7 yr

Major or Mild Frontotemporal NCD
(formerly Frontotemporal Dementia)

Definition
• refers to a group of disorders caused by progressive cell degeneration in the brain's frontal or temporal lobes
  ■ deficits in executive function (e.g. poor mental flexibility, abstract reasoning, response inhibition, planning/organization, increased distractibility) with relative sparing of learning, memory and perceptual–motor function
• “probable” is distinguished from “possible” frontotemporal NCD by:
  ■ evidence of causative frontotemporal NCD genetic mutation, from either family history or genetic testing
  ■ evidence of disproportionate frontal and/or anterior temporal atrophy on MRI or CT
  ■ evidence of frontal and/or anterior temporal hypoperfusion or hypometabolism on PET or SPECT

Behavioural Variant FTD
• most common variant
• insidious onset: must show progressive deterioration of behaviour and/or cognition by observation or history
• typically early symptom presentation (i.e. within the first 3 yr)
• three out of the following symptoms must be present and persistent/recurrent:
  ■ behavioural disinhibition (socially inappropriate behaviour, impulsive, careless)
  ■ apathy or inertia (decreased initiation or continuation of behaviour, requiring cues/prompts, less likely to initiate or sustain conversations)
  ■ loss of sympathy or empathy (diminished response to others' needs/feelings, social interest)
  ■ perseverative, stereotyped, or compulsive/ritualistic behaviour
  ■ hyperorality and dietary changes (binge eating, increased consumption of alcohol/cigarettes or inedible objects)
Language Variants (Primary Progressive Aphasia)

- prominent decline in language ability, in the form of speech production, word finding, object naming, grammar, or word comprehension
- three subtypes
  - nonfluent/agrammatic variant PPA (NFAV-PPA) or progressive nonfluent aphasia (PNFA): non fluent, laboured articulation/speech, anomia, preserved single word comprehension, word-finding deficit, impaired repetition
  - semantic variant PPA (SV-PPA) or semantic dementia (SD): fluent, normal rate, anomia, impaired single word comprehension, intact repetition, use words of generalization ("thing") or suprordinate categories ("animal" for "dog")
  - logopenic progressive aphasia (LPA): naming difficulty and impaired repetition

FTD Movement Disorders

- corticobasal degeneration (CBD) (see Parkinsonism)
- progressive supranuclear palsy (PSP) (see Parkinsonism)

Etiology and Pathogenesis

- unknown, however there is likely a genetic/familial component (40% have family history of early onset NCD)
- genetic variants: MAPT gene (Tau), PGRN gene (progranulin), VCP gene, TARDBP gene (TDP-43), CHMP2D gene
- unlike AD, FTD does not show amyloid plaques or neurofibrillary tangles, instead it is characterized by severe atrophy and specific neuronal inclusion bodies
- gross changes: atrophy in the frontal and anterior temporal lobes; cortical thinning; possible ventricular enlargement
- histological changes: gliosis, swollen neurons, microvacuolation, inclusion bodies in neurons/glia (Tau or TDP-43)

Epidemiology

- fourth most common cause of dementia (5% of all dementia cases)
- common cause of early-onset NCD in individuals younger than 65 yr

Prognosis

- median survival being 6-11 yr after symptoms onset and 3-4 yr after diagnosis
- survival is shorter and decline is faster than in typical Alzheimer’s disease

Major or Mild Vascular NCD

Definition

- diagnosis of major or mild NCD with determination of CVD as the dominant if not exclusive pathology that accounts for the cognitive deficits
- vascular etiology suggested by one of the following:
  - onset of cognitive deficits is temporally related to one or more cerebrovascular events
  - evidence for decline is prominent in complex attention (including processing speed) and frontal-executive function
- neuroimaging evidence of cerebrovascular disease comprises one or more of the following:
  - one or more large vessel infarct or hemorrhage
  - a strategically placed single infarct or hemorrhage (e.g. angular gyrus, thalamus, basal forebrain)
  - two or more lacunar infarcts outside the brainstem
  - extensive and confluent white matter lesions
- for mild vascular NCD: history of a single stroke or extensive white matter disease is sufficient
- for major vascular NCD: history of two or more strokes, a strategically placed stroke, or a combination of white matter disease and one or more lacunae is generally necessary
- associated features supporting diagnosis: personality and mood changes, abulia, depression, emotional lability, and psychomotor slowing

Etiology and Pathogenesis

- major risk factors are the same as those for CVD (i.e. HTN, DM, smoking, obesity, high cholesterol levels, high homocysteine levels, other risk factors for atherosclerosis, atrial fibrillation, and conditions increasing risk of cerebral emboli)
- major or mild vascular NCD with gradual onset and slow progression is generally due to small vessel disease leading to lesions in white matter, basal ganglia, and/or thalamus
- cognitive deficits can be attributed to disruption of cortical-subcortical circuits

Epidemiology

- second most common cause of NCD
- prevalence estimates for vascular dementia/NCD range from 0.2 13% (by age 70), 16% (ages 80+) to 44.6% (ages 90+)
- higher prevalence in African Americans compared to Caucasians and East Asians
- prevalence higher in males than in females
Creutzfeldt-Jakob Disease

- rare degenerative fatal brain disorder caused by prion proteins causing spongiform changes, astrocytosis, and neuronal loss
- most common forms are sporadic (85%), hereditary (5-10%), and acquired (<1%)
- investigations: CSF analysis, MRI brain (cortical and/or subcortical FLAIR changes), EEG (periodic complexes)
- definitive diagnosis is by brain biopsy
- no treatments currently exist

Aphasia

Definition
- an acquired disturbance of language characterized by errors in language production, writing, comprehension, or reading

Neuroanatomy of Aphasia
- Broca's area (posterior inferior frontal lobe) involved in language production (expressive)
- Wernicke's area (posterior superior temporal lobe) involved in comprehension of language (receptive)
- angular gyrus is responsible for relaying written visual stimuli to Wernicke's area for reading comprehension
- arcuate fasciculus association bundle connects Wernicke's and Broca's areas

Assessment of Language
- assessment of context
  • handedness (writing, drawing, toothbrush, scissors), education level, native language, learning difficulties
- assessment of aphasia
  • spontaneous speech (fluency, paraphasias, repetition, naming, comprehension – auditory and reading, writing, neologisms)

Figure 19. Aphasia classification

Prion proteins have a normal form and an infectious form, which results from conversion of the protein from α-helix (normal) to β-pleated sheet (abnormal); these abnormally folded proteins aggregate leading to neuronal loss

>99% of right-handed people have left hemisphere language representation

70% of left-handed people have left hemisphere language representation, 15% have right hemisphere representation, and 15% have bilateral representation

Types of Paraphasias
Semantic (“chair” for “table”)
Phonemic (“clable” for “table”)

Aphasia localizes the lesion on to the dominant cerebral hemisphere

Types of Transcortical Aphasia

- Broca's Motor TCA* (posterior inferior frontal lobe)
- Motor TCA* (frontal lobe watershed between MCA & ACA territories)
- Wernicke's Sensory TCA* (posterior superior temporal lobe, temporal lobe watershed between MCA & PCA territories)
- Conduction Anomic (arcuate fasciculus)
- Mixed TCA*
- Global

* Transcortical aphasia are typically associated with cerebral anoxia (e.g. post-MI, CO poisoning, hypotension)
Mild Traumatic Brain Injury

Definition
- mild TBI = concussion
- trauma induced transient alteration in mental status that may involve loss of consciousness
- hallmarks of concussion: confusion and amnesia which may occur within minutes
- loss of consciousness (if present) must be less than 30 min, initial GCS must be between 13-15, and post-traumatic amnesia must be less than 24 h

Epidemiology
- 75% of TBIs are estimated to be mild; remainder are moderate or severe (see Neurosurgery, NS30 and Emergency Medicine, ER8)
- highest rates in children 0-4 yr, adolescents 15-19 yr, and elderly >65 yr

Clinical Features
- impairments following mild TBI
  - somatic: headache, sleep disturbance, nausea, vomiting, blurred vision
  - cognitive dysfunction: attentional impairment, reduced processing speed, drowsiness, amnesia
  - emotion and behaviour: impulsivity, irritability, depression
  - severe concussion: may precipitate seizure, bradycardia, hypotension, sluggish pupils
  - associated conditions: brain contusion, diffuse axonal injury, C-spine injury

Apraxia

Definition
- inability to perform skilled voluntary motor sequences that cannot be accounted for by weakness, ataxia, sensory loss, impaired comprehension, or inattention

Clinicopathological Correlations

Table 14. Apraxia

<table>
<thead>
<tr>
<th>Description</th>
<th>Tests</th>

<td>Dressing</td>
</tr>
</tbody>
</table>

*Refers specifically to the inability to carry out the learned movements involved in constructing, drawing, or dressing; not merely the inability to construct, draw, or dress. Many skills aside from praxis are needed to carry out these tasks.

Agnosia

Definition
- disorder in the recognition of the significance of sensory stimuli in the presence of intact sensation and naming

Clinicopathological Correlations

Table 15. Agnosias

<table>
<thead>
<tr>
<th>Description</th>
<th>Lesion</th>
</tr>
</thead>
<tbody>
<tr>
<td>Apperceptive Visual Agnosia</td>
<td>Inability to name or demonstrate the use of an object presented visually 2° to distorted visual perception Bilateral temporo-occipital cortex</td>
</tr>
<tr>
<td>Associative Visual Agnosia</td>
<td>Inability to name an object presented visually 2° to disconnect between visual cortex and language areas Visual perception is intact as demonstrated by visual matching Bilateral inferior temporo-occipital junction</td>
</tr>
<tr>
<td>Prosopagnosia</td>
<td>Inability to recognize familiar faces in the presence of intact visual perception and intact auditory recognition Bilateral temporo-occipital areas or right inferior temporo-occipital region</td>
</tr>
<tr>
<td>Colour Agnosia</td>

<td>Inability to identify objects by touch Anterior parietal lobe in the hemisphere opposite the affected hand</td>
</tr>
<tr>
<td>Finger Agnosia</td>
<td>Inability to recognize, name, and point to individual fingers Dominant hemisphere parietal-occipital lesions</td>
</tr>
</tbody>
</table>

Parietal Lobe Lesions
- Lesions of the dominant parietal lobe are characterized by Gerstmann’s syndrome: acalculia, agraphia, finger agnosia, and left-right disorientation
- Lesions of the non-dominant parietal lobe are characterized by neglect, anosognosia, and asomatognosia
- Cortical sensory loss (graphesthesia, astereognosia, impaired 2 point discrimination and extinction) can be seen with left or right parietal lesions

Mild Traumatic Brain Injury

Definition
- mild TBI = concussion
- trauma induced transient alteration in mental status that may involve loss of consciousness
- hallmarks of concussion: confusion and amnesia which may occur within minutes
- loss of consciousness (if present) must be less than 30 min, initial GCS must be between 13-15, and post-traumatic amnesia must be less than 24 h

Epidemiology
- 75% of TBIs are estimated to be mild; remainder are moderate or severe (see Neurosurgery, NS30 and Emergency Medicine, ER8)
- highest rates in children 0-4 yr, adolescents 15-19 yr, and elderly >65 yr

Clinical Features
- impairments following mild TBI
  - somatic: headache, sleep disturbance, nausea, vomiting, blurred vision
  - cognitive dysfunction: attentional impairment, reduced processing speed, drowsiness, amnesia
  - emotion and behaviour: impulsivity, irritability, depression
  - severe concussion: may precipitate seizure, bradycardia, hypotension, sluggish pupils
  - associated conditions: brain contusion, diffuse axonal injury, C-spine injury

Extent of retrograde amnesia correlates with severity of injury
- Regained from most distant to recent memories
Investigations

- neurological exam to identify focal neurologic deficits
- neurocognitive assessment
  - simple orientation questions are inadequate to detect cognitive changes
  - initial assessment of severity is determined by
    - Glasgow Coma Scale: mild: 13-15, moderate: 9-12, severe: 3-8
    - sideline evaluation: Standardized Assessment of Concussion, Westmead Post-Traumatic Amnesia Scale, Sport Concussion Assessment Tool
- neuroimaging
  - x-ray of skull: not indicated for routine evaluation of MTBI
  - CT head as indicated by Canadian CT Head Rules (see Emergency Medicine, ER8)
  - MRI not indicated in initial evaluation – indicated in presence of continued or worsening symptoms despite normal CT

Treatment

- observation for first 24 h after mild TBI in all patients because of risk of intracranial complications
- emergency department for assessment if any loss of consciousness or persistent symptoms
- hospitalization with normal CT if GCS <15, seizures, or bleeding diathesis; or abnormal CT scan
- early rehabilitation to maximize outcomes
  - OT, PT, SLP, vestibular therapy, driving, therapeutic recreation
  - pharmacological management of headaches, pain, depression
  - CBT, relaxation therapy
- follow Return to Play guidelines (www.thinkfirst.ca)

Prognosis

- most recover from mild TBI with minimal treatment, but some experience long-term consequences
- Patients with a previous concussion are at increased risk of subsequent concussion and cumulative brain injury
- repeat TBI can lead to life threatening cerebral edema (controversially known as second impact syndrome) or permanent impairment
- sequela include
  - post-concussion syndrome: dizziness, headache, neuropsychiatric symptoms, cognitive impairment (usually resolves within weeks to months)
  - post-traumatic headaches: begin within 7 d of injury
  - post-traumatic epilepsy: approximately 2% risk of epilepsy post-mild TBI, prophylactic anticonvulsants not effective
  - post traumatic vertigo

---

**Neuro-Oncology**

**Paraneoplastic Syndromes**

- see Endocrinology, E48

**Tumours of the Nervous System**

- see Neurosurgery, NS39

---

**Movement Disorders**

**Function of the Basal Ganglia**

- the cerebral cortex initiates movement via excitatory (glutamatergic) projections to the striatum, which then activate two pathways: direct and indirect
- direct: cortex activates the thalamus allowing movement
- indirect: inhibits the thalamus and ultimately prevents movement
Figure 20. Neural connections of the basal ganglia

Figure 21. Horizontal section of basal ganglia
Overview of Movement Disorders

Table 16. Movement Disorder Definitions

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>

2. Chorea: Huntington’s disease (HD), HD-like syndromes, neuroacanthocytosis, SLE, APLA syndrome, Wilson’s disease, CVD, tardive dyskinesia, senile chorea, Sydenham’s chorea, pregnancy chorea (chorea gravidarum)

3. Dystonia
   - primary dystonia: familial, sporadic (torticollis, blepharospasm, writer’s cramp)
   - dystonia-plus syndromes: dopa-responsive dystonia, myoclonus-dystonia
   - secondary dystonia: thalamotomy, stroke, CNS tumour, demyelination, PNS injury, drugs/toxins (L-dopa, neuroleptics, anticonvulsants, Mn, CO, cyanide, methanol)
   - heredodegenerative dystonias: Parkinsonian disorders, Wilson’s disease, Huntington’s disease

4. Myoclonus
   - physiologic myoclonus: hiccups, nocturnal myoclonus
   - essential myoclonus: myoclonus-dystonia with minimal or no occurrence of dystonia
   - epileptic myoclonus
   - symptomatic myoclonus
   - degenerative disorders: Wilson’s disease, Huntington’s disease, Corticobasal degeneration
   - infectious disorders: CJD, viral encephalitis, AIDS-dementia complex
   - metabolic disorders: drug intoxication/withdrawal, hypoglycemia, hyponatremia, HHS, hepatic encephalopathy, uremia, hypoxia
   - focal brain damage: head injury, stroke, mass

In some cases, dystonias may only occur during voluntary movement and sometimes only during specific activities such as writing, chewing, or speaking (task-specific dystonia).

Hemiballismus is most often due to a vascular lesion of the contralateral subthalamic nucleus.

Myoclonus is often stimulus-sensitive as it can be induced by sudden noise, movement light, visual threat, or pinprick.

In a young patient (<45) must do TSH (thyroid disease), ceruloplasmin (Wilson’s disease), and CT/MRI (cerebellar disease) as indicated by type of tremor.

The majority of essential tremor does not need treatment.

Alcohol
   - Dampens essential tremor
   - Potentiates intention tremor during abstinence (delirium tremens)
   - Does not improve resting tremor of PD

Most common cause of chorea is drug therapy for PD (L-dopa induced dyskinesias).

Palatal myoclonus can result from lesion to the Dentato-Rubro-Olivary tract, and is associated with an audible clicking and tremor of other facial muscles.
### Parkinson’s Disease

**Etiology**
- sporadic: combination of oxidative stress to dopaminergic neurons, environmental toxins (e.g. pesticides), accelerated aging, genetics
- familial (10%): autosomal dominant α-synuclein or LRRK2 mutations, autosomal recessive parkin, PINK1 or DJ-1 mutation (juvenile onset)
- MPTP (neurotoxin)

**Epidemiology**
- prevalence of 0.3% in industrialized countries, but rises with increased age
- second most common neurodegenerative disorder, after Alzheimer’s
- mean age of onset is 60 yr

**Associated Factors**
- risk: family history, male, head injury, rural living, exposure to certain neurotoxins
- protective: coffee drinking, smoking, NSAID use, estrogen replacement in post-menopausal women

**Pathophysiology**
- loss of dopaminergic neurons in pars compacta of substantia nigra → decreased opamine in striatum → 1. disinhibition of the indirect pathway & 2. decreased activation of the direct pathway → increased inhibition of cortical motor areas
- α-synucleinopathy: α-synuclein accumulates in Lewy bodies and causes neurotoxicity in substantia nigra

**Clinical Features**
- positive motor
  - resting tremor: asymmetric 4-5 Hz “pill-rolling” tremor, especially in hands
  - rigidity: lead-pipe rigidity with cogwheeling due to superimposed tremor
- negative motor
  - bradykinesia: slow, small amplitude movements, fatiguing of rapid alternating movements, difficulty initiating movement
- related findings: masked facies, hypophonia, aprosody (monotonous speech), dysarthria, micrographia, shuffling gait with decreased arm swing
- freezing of gait: occurs with walking triggered by initiating stride or barriers/destinations, lasting seconds
- postural instability: late finding presenting as falls
- cognition: bradyphrenia (slow to think/respond), dementia (late finding)
- behavioural: decreased spontaneous speech, depression, sleep disturbances, anxiety
- autonomic: constipation, urinary retention, sexual dysfunction, orthostatic hypotension, clonicogenic hypertension

**Treatment**
- pharmacologic
  - mainstay of treatment: levodopa/carbidopa (Sinemet®) or levodopa/benserazide (Prolopa®).
  - Levodopa is a dopamine precursor; carbidopa and benserazide decreases peripheral metabolism of levodopa, decreasing side effects and increasing half-life of levodopa
  - levodopa-related fluctuation: delayed onset of response (affected by mealtime), end-of-dose deterioration (“wearing-off”), random oscillations of on-off symptoms
  - major complication of levodopa is dyskinesia
  - treatment of early PD: dopamine agonists, amantadine, MAOI
  - adjuncts: dopamine agonists, MAOI, anticholinergics (especially if prominent tremors), COMT inhibitors
- surgical
  - thalamotomy
  - pallidotomy
  - DBS (thalamic, pallidal, subthalamic)
- psychiatric
  - SSRIs first line
  - TCAs (beware fall risk, cognitive impairment, and worsening symptoms of Parkinson’s disease)

### Other Parkinsonian Disorders

- NCD with Lewy bodies (see *Behavioural Neurology, N25*)
- progressive supranuclear palsy: tauopathy with limited gaze (downgaze more specific), early falls, axial rigidity and akinesia, dysarthria, and dysphagia
- corticobasal syndrome: tauopathy with varied presentations but classically presents with unilateral parkinsonism, dystonia/myoclonus, apraxia ± “alien limbs” phenomenon; may also present as progressive non-fluent aphasia
- multiple system atrophy: synucleinopathy presenting as either cerebellar predominant (MSA-C, previously olivopontocerebellar atrophy) or parkinsonism predominant (MSA-P, previously nigrostriatal degeneration); both are associated with early autonomic dysfunction (previously Shy-Drager syndrome)
- vascular parkinsonism: multi-infarct presentation with gait instability and lower body parkinsonism; less likely associated with tremor

**2015 MDS Clinical Diagnostic Criteria for PD**

- “Clinically Established PD” requires:
  - Cardinal Parkinsonism Manifestations: Bradykinesia with either rest tremor or rigidity
  - 2 or more supportive criteria (clear and dramatic beneficial response to dopaminergic therapy, levodopa-induced dyskinesia, rest tremor of a limb, olfactory loss/cardiac sympathetic denervation on MBG scintigraphy)
  - No absolute exclusion criteria and no red flags (see full diagnostic criteria - Postuma et al (2015). Mov Disord.)

**Consider an Alternative Diagnosis if Atypical Parkinsonism**

- Poor response to levodopa
- Abrupt onset of symptoms
- Rapid progression
- Early falls
- Early autonomic dysfunction
- Symmetric symptoms at onset
- Early age of onset (<50 yr)
- Early cognitive impairment
- FHs of psychiatric/dementing disorders
- Recent diagnosis of psychiatric disease
- History of encephalitis
- Unusual toxin exposure
- Extensive travel history

**Dopamine Agonist Therapy in Early Parkinson’s Disease**

*Cochrane DB Syst Rev 2009;2:CD006664*

**Study:** Meta-analysis of trials of dopamine agonists in early Parkinson’s disease.

**Results:** Twenty-nine trials were included (n=5,247). Dopamine agonists were found to have decreased motor effects (dyshkinesia [OR 0.51], dyskinesia [IR 0.64], motor fluctuations [OR 0.75]) compared to levodopa, but provided poorer symptom control compared to levodopa. Also, other side effects were increased (constipation [IR 1.59], hallucinations [IR 1.88], diziness [IR 1.45]).

**Conclusion:** Dopamine agonists have fewer motor side effects than levodopa, but provide worse symptom control and increased rate of other side effects.
Huntington’s Disease

**Etiology and Pathogenesis**
- genetics: autosomal dominant CAG repeats (with anticipation) in Huntington’s gene on Chromosome 4, which leads to accumulation of defective protein in neurons
- pathology: global cerebral atrophy, especially affecting the striatum, leading to increased activity of the direct pathway, and decreased activity of the indirect pathway

**Epidemiology**
- North American prevalence 4-8/100,000
- mean age of onset 35-44 yr; but varies with degree of anticipation from 5-70 yr

**Clinical Features**
- typical progression: insidious onset with clumsiness, fidgetiness, and irritability, progressing over 15 yr to major NCD, psychosis, and chorea
  - major NCD: progressive memory impairment and loss of intellectual capacity
  - chorea: begins as movement of eyebrows and forehead, shrugging of shoulders, and parakinesia (pseudo-purposeful movement to mask involuntary limb jerking)
  - progresses to dance-like or ballism, and in late stage is replaced by dystonia and rigidity
  - mood changes: irritability, depression, anhedonia, impulsivity, bouts of violence
- Juvenile onset HD (Westphal variant) characterized by Parkinsonism and dystonia

**Investigations**
- MRI: enlarged ventricles, atrophy of cerebral cortex and caudate nucleus
- genetic testing
  - expansion of the cytosine-adenine-guanine (CAG) trinucleotide repeats in the HTT gene
  - CAG repeats on chromosome 4p16.3 that encodes the protein huntingtin

**Treatment**
- no disease altering treatment
- psychiatric symptoms: antidepressants and antipsychotics
- chorea: neuroleptics and benzodiazepines
- dystonia: botulinum toxin

Dystonia

**Epidemiology**
- third most common movement disorder after Parkinson’s disease and essential tremor

**Clinical Features**
- sustained twitching movements caused by co-contraction of agonist and antagonist muscles
- symptoms exacerbated by fatigue, stress, emotions; relieved by sleep or specific tactile/proprioceptive stimuli (‘geste antagoniste’, e.g. place hand on face for cervical dystonia)
- more likely to be progressive and generalize if younger onset or leg dystonia

**Treatment**
- local medical: botulinum toxin
- systemic medical: anticholinergics (benztropine), muscle relaxants (baclofen), benzodiazepines, dopamine depleters (tetrabenazine); dopamine for dopa-responsive dystonia
- surgical: surgical denervation of affected muscle, stereotactic thalamotomy (unilateral dystonia), posteroventral pallidotomy, or DBS

Tic Disorders

**Definition**
- a tic is a sudden, rapid, recurrent, nonrhythmic, stereotyped motor movement or vocalization
- common criteria
  - tics may wax and wane in frequency but have persisted for an extended period of time
  - onset before age 18 yr
  - disturbance is not attributable to the physiological effects of a substance or another medical condition

**Clinical Classification**
- **Tourette’s Syndrome**: multiple motor and one or more vocal tics that have persisted for more than 1 yr since onset
- **persistent (chronic) motor or vocal tic disorder**: single or multiple motor or vocal tics (but not both motor and vocal) that have persisted for more than 1 yr since onset
- **provisional tic disorder**: single or multiple motor and/or vocal tics present for <1 yr since first tic onset
- other specified or unspecified tic disorder: symptoms characteristic of a tic disorder but do not meet full criteria
- **secondary tic disorders**: encephalitis, CJD, Sydenham’s chorea, head trauma, drugs, mental retardation syndromes
Tic Types
- simple tics: short duration (milliseconds)
- complex tics: longer (seconds), more purposeful and often include a combination of simple tics
- motor tics:
  - simple: blinking, head jerking, shoulder shrugging, extension of the extremities
  - complex: copropraxia (obscene gestures), echopraxia (imitate gestures), throwing, touching
- vocal tics:
  - simple: blowing, coughing, grunting, throat clearing
  - complex: coprolalia (shout obscenities), echolalia (repeat others' phrases), palilalia (repeat own phrases)

Treatment
- dopamine blockers, dopamine depletors (tetrabenazine), clonidine, clonazepam, DBS

**Tourette’s Syndrome (Gilles de la Tourette Syndrome)**

**Definition According to DSM V**
1. presence of both multiple motor and one or more vocal tics at some point during the illness, although not necessarily concurrently
2. tics may wax and wane in frequency but have persisted for more than 1 yr since first tic onset (with no tic-free periods greater than 3 mo)
3. onset is before age 18 yr
4. not due to effect of a substance or another medical condition

**Epidemiology**
- estimated prevalence among adolescents 3-8 per 1,000 school-age children; M:F = 2:1 to 4:1

**Signs and Symptoms**
- tics: wide variety that wax and wane in type and severity; can be voluntarily suppressed for some time but are preceded by unpleasant sensation that is relieved once tic is carried out
  - can be worsened by anxiety, excitement, and exhaustion; better during calm focused activities
- psychiatric: compulsive behaviour (associated with OCD and ADHD), hyperactive behaviour, ‘rages’, sleep-wake disturbances, learning disabilities

Treatment
- same as tics (dopamine blockers, dopamine depletors, clonidine, clonazepam, DBS)

**Prognosis**
- typically begins between ages 4-6
- peak severity occurs between ages 10-12, with a decline in severity during adolescence (50% are tic-free by 18 yr of age)
- tic symptoms, however, can manifest similarly in all age groups and across the lifespan

**Cerebellar Disorders**

**Clinico-Anatomic Correlations**
- vermis: trunk/gait ataxia
- cerebellar lobe (i.e. lateral): rebound phenomenon, scanning dysarthria, dysdiadochokinesia, dysmetria, nystagmus

**Symptoms and Signs of Cerebellar Dysfunction**
- nystagmus: observe during extraocular movement testing (most common is gaze-evoked nystagmus)
- dysarthria (ataxic): abnormal modulation of speech velocity and volume – elicit scanning/telegraphic/shurred speech on spontaneous speech
- ataxia: broad-based, uncoordinated, lurching gait
- dysmetria: irregular placement during voluntary movement of limb or eye
- dysdiadochokinesia: impairment of rapid alternating movements (e.g. pronation – supination task)
- postural instability: truncal ataxia on sitting, titubation (rhythmic rocking of trunk and head), difficulty with tandem and broad-based gait
- intention tremor: typically orthogonal to intended movement, and increases as target is approached
- hypotonia: decreased resistance to passive muscular extension (occurs shortly after injury to lateral cerebellum)
- pendular patellar reflex: knee reflex causes pendular motion of leg (occurs after injury to cerebellar hemispheres); pendular reflexes at triceps
- rebound phenomenon: overcorrection after displacement of a limb
- hypometric and hypermetric saccades
**Wernicke-Korsakoff Syndrome**

- see Psychiatry: PS24
- note that alcohol can also cause a cerebellar ataxia separate from thiamine deficiency; this ataxia can be due to cerebellar atrophy or alcohol polyneuropathy

**Cerebellar Ataxias**

**Congenital Ataxias**
- early onset non-progressive ataxias associated with various syndromes as well as developmental abnormalities (e.g. Arnold-Chiari malformation, Dandy-Walker cysts)

**Hereditary Ataxias**
- autosomal recessive: includes Friedrich’s ataxia, ataxia with oculomotor apraxia, ataxia telangiectasia, vitamin E deficiency
  - Friedrich’s ataxia: prevalence 2/100,000; typical onset between 8 and 15 yr
    - signs: gait and limb ataxia, weakness, areflexia, extensor plantar reflex, impaired proprioception and vibration, dysarthria
    - death in 10-20 yr from cardiomyopathy or kyphoscoliotic pulmonary restriction
- autosomal dominant: most commonly spinocerebellar ataxias (SCAs) (over 30 types, most common SCAs due to CAG repeats)
  - signs: ataxia and dysarthria, chorea, polyneuropathy, pyramidal and/or extrapyramidal features, dementia

**Acquired Ataxias**
- neurodegeneration: e.g. multiple system atrophy
- systemic: alcohol, celiac sprue, hypothyroidism, Wilson’s, thiamine deficiency
- toxins: carbon monoxide, heavy metals, lithium, anticonvulsants, solvents
- vascular: infarct, bleed, basilar migraine
- autoimmune: MS, Miller-Fischer (GBS)

**Vertigo**

- see Otolaryngology: OT12

**Motor Neuron Disease**

**Amyotrophic Lateral Sclerosis (Lou Gehrig’s Disease)**

**Definition**
- progressive neurodegenerative disease that causes UMN and LMN symptoms and is ultimately fatal

**Etiology**
- idiopathic (most), genetic (5-10% familial, especially SOD1 mutation, other: C9orf72, TARDBP)

**Pathology**
- disorder of anterior horn cells of spinal cord, cranial nerve nuclei, and corticospinal tract

**Epidemiology**
- 5/100,000; incidence increases with age

**Clinical Features**
- limb motor symptoms: segmental and asymmetrical UMN and LMN symptoms
- bulbar findings: dysarthria (flaccid or spastic), dysphagia, tongue atrophy and fasciculations, facial weakness and atrophy
- pseudobulbar affect, frontotemporal dementia (up to 10%)
- sparing of sensation, ocular muscles, bowel, bladder, sphincters

**Investigations**
- EMG: chronic denervation and reinnervation, fasciculations
- NCS: to rule out peripheral neuropathy (i.e. multifocal motor neuropathy with conduction block)
- CT/MRI: to rule out cord disease/compression

---

Red Flags Inconsistent with ALS
- Sensory Sx, predominant pain, bowel or bladder incontinence, cognitive impairment, ocular muscle weakness

Denervation on EMG
- Fibrillations, positive sharp waves, complex repetitive discharges; reinnervation — increased amplitude and duration of motor units

The only interventions that have been shown to extend survival in ALS are riluzole and use of BiPAP
**Peripheral Neuropathies**

### Treatment
- *riluzole* (modestly slows disease progression)
- symptomatic relief
  - spasticity/cramping: baclofen, tizanidine (Zanaflex®), regular exercise, and physical therapy
  - sialorrhea: TCA (i.e. amitriptyline), sublingual atropine drops, parotid/submandibular Botox® (rare)
  - pseudobulbar affect: dextromethorphan/quinidine, TCA, SSRI
- non-pharmacologic: high caloric diet, ventilatory support (especially BiPAP), early nutritional support (i.e. PEG tube), rehabilitation (PT, OT, SLP), psychosocial support

### Prognosis
- median survival 3 yr; death due to respiratory failure

### Other Motor Neuron Diseases
- degenerative
  - *progressive muscular atrophy* (progressive bulbar palsy): only LMN symptoms with asymmetric weakness, later onset than ALS, 5-10% of patients in ALS centres
  - *primary lateral sclerosis* (progressive pseudobulbar palsy): UMN symptoms, later onset, not fatal, variable disability; 5-10% of patients in ALS centres
  - *spinal muscular atrophy*: pediatric disease with symmetric LMN symptoms
- infectious
  - post-polio syndrome, West Nile infection: residual asymmetric muscle weakness, atrophy

### Diagnostic Approach to Peripheral Neuropathies
1. differentiate: motor vs. sensory vs. autonomic vs. mixed
2. pattern of deficit: symmetry; focal vs. diffuse; upper vs. lower limb; cranial nerve involvement
3. temporal pattern: acute vs. chronic; relapsing/remitting vs. constant vs. progressive
4. history: PMH, detailed FHx, exposures (e.g. insects, toxins, sexual, travel), systemic symptoms
5. detailed peripheral neuro exam: LMN findings, differentiate between root and peripheral nerves, cranial nerves, respiratory status

**Figure 22. Pattern of distribution for peripheral neuropathies**

#### Classification
- **monoradiculopathy**: dermatomal deficit due to single nerve root lesion
  - due to disc herniation or root compression causing radicular pain
  - little tactile anesthesia, as dermatomes overlap
- **polyradiculopathy**: multiple dermatome deficits due to multiple nerve root lesions
  - one type is cauda equina syndrome (lumbosacral roots)
- **plexopathy**: deficit matching distribution of a nerve plexus
  - **brachial plexopathy**
    - upper (C5-C7): LMN Sx of shoulder and upper arm muscles (Erbs palsy)
    - lower (C8-T1): LMN Sx and sensory Sx of forearm and hand (Klumpke's palsy)
    - **DDx**: trauma, idiopathic neuritis, tumour infiltration, radiation, thoracic outlet syndrome (i.e. cervical rib)
  - **lumbosacral plexopathy** (rare, especially unilateral)
    - **DDx**: idiopathic neuritis, infarction (i.e. DM), compression

**Diabetic Neuropathies**
- Peripheral neuropathy: pain or loss of sensation in a glove and stocking distribution (hands and feet affected before arms and legs)
- Autonomic: anhidrosis, orthostatic hypotension, impotence, gastroparesis, bowel and bladder dysfunction
- Mononeuropathy multiplex: nerve infarct or compression
- Cranial neuropathy: CN III (pupil sparing) > IV > VI
- Lumbosacral plexopathy

**Tinel’s Sign**
Tap lightly over the median nerve at the wrist, the patient’s symptoms of carpal tunnel will be elicited in a positive test

**Phalen’s Test**
Hold both wrists in forced flexion (with the dorsal surfaces of the hands pressed against each other) for 30-60 s; test is positive if symptoms of carpal tunnel are elicited

**DDx of Demyelinating Neuropathy**
GBS, CIDP, paraproteinemia, diphtheria, amyloidosis, Charcot-Marie-Tooth, storage diseases, pressure palsy predisposition, paraneoplastic
• **mononeuropathy**: single nerve deficit
  • **carpal tunnel syndrome** (most common): compression of median nerve at wrist
    • symptoms: wrist pain, paresthesia first 3 ½ digits, ± radiation to elbow, worse at night
    • signs: Tinel’s sign, Phalen’s test, thenar muscle wasting, sensory deficit
    • etiology: entrapment, pregnancy, DM, gammopathy, rheumatoid arthritis, thyroid disease
  • **Bell’s palsy** (most common cranial neuropathy): see Otolaryngology, OT22
  • **Entrapment/compression**: ulnar (compression at elbow), median (at pronator teres), radial (at spiral groove of humerus), obturator (from childbirth), peroneal (due to crossing legs or surgical positioning), posterior tibial (tarsal canal)
• **mononeuropathy multiplex**: deficit affecting multiple discrete nerves (asymmetric)
  • must rule out vasculitis or collagen vascular disease; consider MMN (multifocal motor neuropathy) or MADSAM (multifocal acquired demyelinating sensory and motor neuropathy)
• **polyneuropathy**: symmetrical distal stocking-glove pattern
  • symmetrical distal sensorimotor deficit affecting longest fibres first (stocking-glove distribution), hypotonia; progression of dysesthesia early and weakness later
  • etiology: DM (most common), renal disease, substances, toxins; genetics, SLE, HIV, leprosy, alcohol, B12 deficiency, uremia
• **chronic inflammatory demyelinating polyneuropathy (CIDP)**
  • chronic relapsing sensorimotor polyneuropathy with increase protein in CSF and demyelination (shown on EMG/NCS)
  • course is fluctuating, in contrast with the acute onset of GBS
  • treatment: first-line is prednisone; alternatives are plasmapheresis, IVIG, and azathioprine

---

A = autonomic; CDP = chronic inflammatory demyelinating polyneuropathy; GGT = gamma-glutamyl transferase; HMSN = hereditary motor sensory neuropathy; M = motor; OGGTT = oral glucose tolerance test; PAN = polyarteritis nodosa; RA = rheumatoid arthritis; S = sensory; SLE = systemic lupus erythematosus; SPEP = serum protein electrophoresis.

---

Axonal neuropathies have decreased amplitude on NCS; demyelinating neuropathies have decreased velocity on NCS

Ototoxic drugs (e.g. aminoglycosides) should not be given to diabetics

Sensory neuropathy of the feet prevent them from adequately compensating for loss of vestibular function

IV G and plasmapheresis lead to more rapid improvement, less intensive care and less ventilation, but do not change mortality or relapse rate

Genetic Testing: Indicated for cryptogenic polyneuropathy exhibiting classic hereditary neuropathy phenotype. Screen for CMT1A duplication/deletion and Cx32 mutations.

A = autonomic; CDP = chronic inflammatory demyelinating polyneuropathy; GGT = gamma-glutamyl transferase; HMSN = hereditary motor sensory neuropathy; M = motor; OGGTT = oral glucose tolerance test; PAN = polyarteritis nodosa; RA = rheumatoid arthritis; S = sensory; SLE = systemic lupus erythematosus; SPEP = serum protein electrophoresis.
Guillain-Barré Syndrome
- **definition**: acute rapidly evolving demyelinating inflammatory polyradiculoneuropathy that often starts in the distal lower limbs and ascends
- **etiology**
  - autoimmune attack and damage to peripheral nerve myelin
  - sometimes preceded by viral/bacterial infections
- **signs and symptoms**
  - sensory: distal and symmetric paresthesias, loss of proprioception and vibration sense, neuropathic pain
  - motor: weakness starting distally in legs, areflexia
  - autonomic: blood pressure dysregulation, arrhythmias, bladder dysfunction
- **investigations**
  - CSF: albuminocytologic dissociation (high protein, normal WBC)
  - EMG/NCS: conduction block, differential or focal (motor > sensory) slowing, decreased F-wave, sural sparing
- **treatment**
  - IVIG or plasmapheresis, ± pain management, monitor vitals and vital capacity
- **prognosis**
  - peak of symptoms at 2-3 wk, resolution at 4-6 wk
  - 5% mortality (higher if require ICU); up to 15% have permanent deficits

Clinical Approach to Disorders of the Neuromuscular Junction

**Myasthenia Gravis**

**Etiology and Pathophysiology**
- progressive autoimmune disorder due to anti-AChR or anti-MuSK antibodies, resulting in early saturation at the NMJ and inadequate muscle activation with increasing nerve stimulation
- 15% of patients with MG have associated thymic neoplasia, 85% have thymic hyperplasia

**Epidemiology**
- bimodal age of onset – 20s (mostly women) and 60s (mostly men)

**Clinical Features**
- fatigable, symmetric or asymmetric weakness without reflex changes, sensory changes, or coordination abnormalities
- ocular (diplopia/ptosis), bulbar (dysarthria/dysphagia), and/or proximal limb weakness
- symptoms may be exacerbated by infection, pregnancy, menses, and various drugs
- respiratory muscle weakness may lead to respiratory failure

**Investigations**
- edrophonium (Tensilon®) test - assess for improvement over 2 min following edrophonium injection
- EMG
  - repetitive stimulation → decremental response
  - single fibre electromyography shows increased jitter (80-100% sensitivity)
- spirometry – forced vital capacity may be used to monitor adequacy of respiratory effort over time
- anti-AChR antibody assay (70-80% sensitivity); anti-MuSK antibody may be used if seronegative for anti-AChR antibody
- CT/MRI to screen for thymoma/thymic hyperplasia

**Neuromuscular Junction Disease**

*Neuromuscular Junction Disease*

Diseases of the neuromuscular junction typically feature prominent fatigability

Fatigability can be tested by holding the arms out or by holding the gaze in the upward position (especially in MG)

Muscle weakness due to fatigability will improve with rest or ice

**Miller-Fisher Variant of GBS – Triad**
- Ophthalmoplegia
- Ataxia
- Areflexia

**GBS** is a neurological emergency due to risk of imminent respiratory failure

The most common antecedent infection in GBS is *Campylobacter jejuni*

**Neuromuscular Junction Diseases**
Neuromuscular Junction Diseases

Treatment
- thymectomy 85% of patients show improvement or remission
- symptomatic relief
- acetylcholinesterase inhibitors (e.g. pyridostigmine) - does not affect primary pathologic process so rarely results in control of disease when used alone
- immunosuppression
- steroids are mainstay of treatment (70-80% remission rate) - azathioprine, cyclophosphamide, and mycophenolate as adjuncts or as steroid sparing therapy
- short-term immunomodulation (for crises) – IVIG and plasmapheresis

Prognosis
- 30% eventual spontaneous remission
- with treatment, life expectancy is equal to that of a person without MG, but quality of life may vary

Lambert-Eaton Myasthenic Syndrome

Etiology and Pathophysiology
- autoimmune disorder due to antibodies against presynaptic voltage-gated calcium channels, causing decreased ACh release at the NMJ
- 50-66% are associated with small cell carcino ma of the lung

Clinical Features
- weakness of skeletal muscles without sensory or coordination abnormalities, proximal and lower muscles more affected
- reflexes are diminished or absent, but increase after active muscle contraction
- bulbar and ocular muscles affected in 25% (vs. 90% in MG)
- prominent anticholinergic autonomic symptoms (dry mouth > impotence > constipation > blurred vision)

Investigations
- edrophonium test → no response
- EMG
  - rapid (>10 Hz) repetitive stimulation → incremental response
  - post-exercise facilitation → an incremental response with exercise
- screen for malignancy, especially small cell lung cancer

Treatment
- tumour removal
- acetylcholine modulation
  - increased acetylcholine release (3,4-diaminopyridine)
  - decreased acetylcholine degradation (pyridostigmine)
- immunomodulation - steroids, plasmapheresis, IVIG

Botulism

Etiology and Pathophysiology
- caused by a toxin produced by spores of Clostridium botulinum bacteria, which can enter through wounds or by ingestion
- infantile botulism is the most common form, and is usually from ingestion of honey or corn syrup

Clinical Features
- occur 6-48 h after ingestion
- CN paralysis: ptosis, extraocular muscle weakness, dilated poorly reactive pupils, dysarthria, jaw weakness, dysphagia
- autonomic dysfunction: nausea, orthostatic hypotension, constipation (paralytic ileus), bladder distension
- anticholinergic symptoms: dry mouth, constipation, urinary retention
- spreads to trunk and limbs: symmetric weakness with paralysis and absent/decreased deep tendon reflexes
- pattern of paresis often starts with GI symptoms, then extraocular muscle weakness, then dysphagia, then limbs and respiratory involvement; all associated with dry mouth.
- rarely respiratory distress, potentially advancing to respiratory failure

Investigations
- blood test for toxin, stool culture
- CT/MRI to rule out stroke, lesion (normal in botulism)

Treatment
- botulinum anti-toxin – good prognosis with prompt treatment
- supportive therapy as required

Tensilon® is a drug that inhibits acetylcholinesterase. It improves muscle function immediately in myasthenia gravis, but not in a cholinergic crisis. This test is infrequently used; when performed, a crash cart should be nearby as respiratory difficulty and/or bradycardia may occur.

Myotonic Dystrophy

**Etiology and Pathophysiology**
- unstable trinucleotide (CTG) repeat in DMK gene (protein kinase) at 19q13.3, number of repeats correlates with severity of symptoms, autosomal dominant

**Epidemiology**
- most common adult muscular dystrophy, prevalence 3-5/100,000

**Clinical Features**
- appearance: ptosis, bifacial weakness, frontal baldness (including women), triangular face giving a drooping/dull appearance
  - physical exam
    - distribution of weakness: distal weaker than proximal (in contrast to other myopathies), steppage gait
    - myotonia: delayed relaxation of muscles after exertion (elicit by tapping on thenar muscles with hammer)
    - cardiac: 90% have conduction defects (1º heart block; atrial arrhythmias)
    - respiratory: hypoventilation 2º to muscle weakness
    - ocular: subcapsular cataracts, retinal degeneration decreased intraocular pressure
    - other: DM, infertility, testicular atrophy
  - EMG: subclinical myotonia – long runs with declining frequency and amplitude

**Treatment and Prognosis**
- no cure, progressive, death usually around 50 yr
- management of myotonia: phenytoin

Pain Syndromes

**Approach to Pain Syndromes**

**Definitions**
- nociceptive pain: pain arising from normal activation of peripheral nociceptors
- neuropathic pain: pain arising from direct injury to neural tissue, bypassing nociceptive pathways
- spontaneous pain: unprovoked burning, shooting, or lancinating pain
- paresthesia: spontaneous abnormal non-painful sensation (e.g. tingling)
- dysesthesia: evoked pain with inappropriate quality or excessive quantity
- allodynia: a dyesthetic response to a non-noxious stimulus
- hyperalgesia: an exaggerated pain response to a noxious stimulus

**Non-Pharmacological Management**
- physical (PT, acupuncture, chiropractic manipulation, massage)
- psychoeducational (CBT, family therapy, education, psychotherapy)

**Medical Pain Control**
- combination multi-modal therapy is important
- primary analgesics: acetaminophen, NSAIDs (often used for soft tissue injuries, strains, sprains, headaches, and arthritis), opiates
- adjuvants: antidepressants (TCAs, SSRIs), anticonvulsants (gabapentin, carbamazepine, pregabalin), baclofen, sympathectomies (phenoxybenzamine), α2-adrenergic agonists (clonidine)

**Surgical Pain Control**
- peripheral ablation: nerve blocks, facet joint denervation
- direct delivery: implantable morphine pump
- central ablation: stereotactic thalamotomy, spinal tractotomy, or dorsal root entry lesion
- DBS or dorsal column stimulation

**Neuropathic Pain**

**Definition**
- pain resulting from a disturbance of the central or peripheral nervous system

**Epidemiology**
- affects up to 6% of people (2 million Canadians)
Symptoms and Signs
- hyperalgesia/allodynia
- subjectively described as burning, heat/cold, prickling, electric shock, perception of swelling, numbness
- can be spontaneous or stimulus evoked, distribution may not fall along classical neuro-anatomical lines
- associated issues: sleep difficulty, anxiety/stress/mood alteration

Causes of Neuropathic Pain
- sympathetic: complex regional pain syndrome
- non-sympathetic: damage to peripheral nerves
  - systemic disease: DM, thyroid disease, renal disease, rheumatoid arthritis, multiple sclerosis
  - nutritional/toxicity: alcoholism, pernicious anemia, chemotherapy
  - infectious: post-herpetic, HIV
  - trauma/compression: nerve entrapment, trigeminal neuralgia, post-surgical, nerve injury, cervical/lumbar radiculopathy, plexopathy
- central: abnormal CNS activity
  - phantom limb, post spinal cord injury, post stroke, MS

Treatment
- identify/treat underlying cause
- pharmacotherapy
  - Stepwise approach (Canadian Pain Society, 2014)
    - 1st line: Gabapentinoids, TCA, SNRI
    - 2nd line: Tramadol, opioid analgesics
    - 3rd line: Cannabinoids
    - 4th line: topical lidocaine (second line for postherpetic neuralgia), methadone, lamotrigine, lacosamide, tapentadol, botulinum toxin
- common non-pharmacologic therapies
  - neuropsychiatry: CBT, psychotherapy
  - rehabilitation: physiotherapy
- surgical therapies: dorsal column neurostimulator, DBS (thalamus)

Trigeminal Neuralgia

Clinical Features
- recurrent episodes of sudden onset, excruciating unilateral paroxysmal shooting “electric” pain in trigeminal root territory (V3>V2>V1)
- may have normal sensory exam
- pain lasts seconds/minutes over days/weeks; may remit for wk/mo
- triggers: touching face, eating, talking, cold wind, shaving, applying make-up

Etiology
- classic TN: idiopathic
- secondary TN: compression by tortuous blood vessel (superior cerebellar artery), cerebellopontine angle tumour (5%), MS (5%)

Epidemiology
- F>M; usually middle-aged and elderly

Diagnosis
- clinical diagnosis
- investigate for secondary causes, which are more likely if bilateral TN or associated sensory loss
  - MRI to rule out structural lesion, MS, or vascular lesion

Treatment
- first line: carbamazepine or oxcarbazepine
- second line: baclofen or lamotrigine
- narcotics not generally recommended
- if medical treatment fails: trigeminal ganglion percutaneous technique, gamma knife, invasive percutaneous denervation (radiofrequency/glycerol), percutaneous balloon microcompression, microvascular decompression

Postherpetic Neuralgia

Clinical Features
- pain persisting in the region of a cutaneous outbreak of herpes zoster
- constant deep ache or burning, intermittent spontaneous lancinating pain, allodynia
- distribution: thoracic, trigeminal, cervical > lumbar > sacral
- associated impaired sleep, decreased appetite, decreased libido
Etiology and Pathogenesis
• destruction of the sensory ganglion neurons (e.g. dorsal root, trigeminal, or geniculate ganglia) secondary to reactivation of herpes zoster infection

Epidemiology
• incidence in those with zoster increases with age (2% in <60 yr, 19% in >70 yr)
• risk factors: older age, greater acute pain, greater rash severity

Prevention
• varicella zoster vaccine (Varivax®) in childhood reduces incidence of varicella zoster
• herpes zoster vaccine (Zostavax®) reduces incidences of shingles, PHN, and other herpetic sequelae (currently recommended in Canada for those >60 yr old)

Treatment
• medical: TCA (i.e. amitriptyline), anti-convulsants (i.e. pregabalin, gabapentin), analgesia (i.e. opiates, lidocaine patch), intrathecal methylprednisolone, topical capsaicin
  • early treatment of acute herpes zoster with antivirals (acyclovir; longer-acting famciclovir and valacyclovir more effective)
  • treatment of herpes zoster with corticosteroids DOES NOT decrease PHN
• surgical: spinal tractotomy, dorsal root entry zone lesion, DBS of thalamus

Painful Diabetic Neuropathy
see Endocrinology, E13

Approach
• determine if pain is neuropathic or vascular
• more likely neuropathic if pain present at rest and improves with walking, pain is sharp/tingling, more in feet than calves

Treatment
• Level A: pregabalin
• Level B: venlafaxine, duloxetine, amitriptyline, gabapentin, valproate, rarely opioids, capsaicin

Complex Regional Pain Syndromes

Clinical Features
• presence of an initiating noxious event (MI, stroke)
• continuing pain, allodynia, or hyperalgesia with pain disproportionate to inciting event evidence during the course of symptoms of edema, changes in skin blood flow or abnormal vasomotor activity
• absence of conditions that would otherwise account for degree of pain and dysfunction
• other features can include edema, osteoporosis, hyperhidrosis, hair loss, fascial thickening

Classification
• CRPS type I (reflex sympathetic dystrophy): minor injuries of limb or lesions in remote body areas precede onset of symptoms
• CRPS type II (causalgia): injury of peripheral nerves precedes the onset of symptoms

Investigations
• trial of differential neural blockade may be helpful in diagnosis
• autonomic testing (evidence of sympathetic dysfunction)
• bone scan, plain radiography, MRI

Prevention
• early mobilization after injury/infarction

Treatment
• goal of treatment: to facilitate function
• conservative treatment: education, support groups, PT/OT, smoking cessation
• medical: topical capsaicin, TCA, NSAIID, tender point injections with corticosteroid/lidocaine, gabapentin/pregabalin/lamotrigine, calcitonin or bisphosphonates, oral corticosteroids
• surgical: paravertebral sympathetic ganglion blockade
• refer to pain management clinic
Headache

Clinical Approach

- **History**
  - pain characteristics: onset, frequency, duration, intensity, location, radiation, other specific features (e.g., worse in AM, worse with bending/cough/Valsalva)
  - associated symptoms: visual changes, change in mental status, nausea/vomiting, fever, meningismus, photophobia, phonophobia, TMJ popping/clicking, jaw claudication, neurological symptoms
  - precipitating/alleviating factors (triggering factors, analgesics), medications (especially nitrates, CCBs, NSAIDs, anticoagulants), PMH, FFx
  - red flags (possible indications for CT scan/further investigation): new-onset headache (especially if age <5 or >50), quality worse/different than previous headaches, sudden and severe (‘thunderclap’), immunocompromised, fever, focal neurological deficits, trauma

- **Physical Exam**
  - vitals (including BP and temp), Kernig’s/Brudzinski’s, MSK examination of head and neck
  - HEENT: fundi (papilledema, disc swelling), vitals (including temp, BP, O2), cervical OA, TMJ syndrome
  - full neurological exam (including LOC, orientation, pupils (symmetry), and focal neurological deficits)
  - red flags: papilledema, altered LOC, fever, meningismus, focal neurological deficits, signs of head trauma

Classification

- **Primary**
  - tension, migraine, cluster, other autonomic cephalgias, SUNCT
- **Secondary**
  - cervical OA, TMJ syndrome, SAH, ICH, stroke, venous sinus thrombosis, meningitis/encephalitis, trauma, increased ICP (space-occupying lesion, malignant HTN or pseudotumour cerebri), temporal arteritis, sinusitis, acute-angle closure glaucoma, pre-ecchymosis, post LP, drugs/toxins (e.g., nitroglycerin use and analgesia withdrawal); all can be associated with serious morbidity or mortality

Conclusions and Prophylaxis

**Antiepileptics in Migraine Prophylaxis: An Updated Cochrane Review**
Capovalva 2015;35:51-62

**Purpose:** To review the evidence for anticonvulsants in migraine prophylaxis.

**Study:** Systematic meta-analysis of 37 published and 3 unpublished prospective, controlled trials of regular use of anticonvulsants to prevent migraines and improve quality of life related to migraines.

**Results:** Sodium valproate and topiramate were associated with a reduction of 4 and 1 days of headache per month, respectively, and patients taking either drug were more than two times as likely to experience greater than 50% reduction in headache frequency, versus placebo. Neither drug was associated with undue rates of adverse events though higher doses of topiramate were associated with increased adverse events. There is insufficient evidence of efficacy of other antiepileptic drugs, including gabapentin, for migraine prophylaxis.

**Conclusions:** Daily sodium valproate 400 mg and topiramate 50 mg are well tolerated and effective in prophylactic treatment of migraine headache in adults.

### Migraine Headaches

#### Definition (Common Migraine)
- ≥5 attacks fulfilling each of the following criteria
  - 4-72 h duration
  - 2 of the following: unilateral, pulsating, moderate-severe (interferes with daily activity), aggravated by routine physical activity
  - 1 of the following: nausea/vomiting, photophobia/phonophobia/osmophobia

#### Epidemiology
- 18% females, 6% males; frequency decreases with age (especially at menopause)

#### Etiology and Pathophysiology
- theories of migraine etiology
  - depolarizing wave of “cortical spreading depression” across the cerebral cortex that may cause an aura (e.g. visual symptoms due to wave through occipital cortex) and also activate trigeminal nerve afferent fibres
  - possible association with vasoconstriction/dilation
  - significant genetic contribution
- triggers: stress, sleep deprivation, drugs (estrogen nitroglycerin), hormonal changes, caffeine withdrawal, chocolate, tyramines (e.g. red wine), nitrates (e.g. processed meats)

The oral contraceptive pill is contraindicated with complicated migraine due to risk of stroke.

Migraine auras can mimic other causes of transient neurological deficits (e.g. TIAs and seizures).

"Menstrual Migraine" Subtype
Migraine headache that is associated with the onset of menstruation – usually 2 d before to 3 d after the onset of menstrual bleeding.

If patient presents to ED with severe migraine and N/V – consider treating with IV antiemetics (chlorpromazine, prochlorperazine).
Signs and Symptoms
- stages of uncomplicated migraine
  1. prodrome (hours to days before headache onset)
  2. aura
  3. headache
  4. postdrome
- aura
  - fully reversible symptom of focal cerebral dysfunction lasting <60 min
  - examples: visual disturbance (fortification spectra – zigzags; scintillating scotoma – spots), unilateral paresthesia and numbness or weakness, aphasia
- prodrome/postdrome: appetite change, autonomic symptoms, altered mood, psychomotor agitation/retardation
- classification of migraines
  - common migraine: no aura
  - classic migraine: with aura (headache follows reversible aura within 60 min)
  - complicated migraine: with severe/persistent sensorimotor deficits
    - examples: basilar-type migraine (occipital headache with diplopia, vertigo, ataxia, and altered level of consciousness), hemiplegic/hemisensory migraine, ophthalmoplegic migraine
  - acephalgic migraine (i.e. migraine equivalent): aura without headache

Treatment
- avoid triggers
- mild to moderate migraine
  - 1st line: NSAIDs (ibuprofen, naproxen)
- moderate to severe migraine
  - triptans (most effective), ergots (dihydroergotamine, DHE)
- migraine prophylaxis: anticonvulsants (divalproex, topiramate, gabapentin), TCA (amitriptyline, nortriptyline), propranolol, calcium channel blocker (verapamil)

Sleep Disorders

Overview of Sleep

Definition
- newborn: 18 h sleep (50% REM), adolescents: 10 h, adults: 7-9 h but most get insufficient amounts
- many elderly have reduced sleep as a consequence of underlying sleep disorders

Sleep Architecture
- polysomnogram (PSG) measures: EEG, eye movements (electro-oculogram – EOG), EMG, respiratory effort, oxygenation, ECG

Table 24. Sleep Stage Characteristics

<table>
<thead>
<tr>
<th>EEG</th>
<th>EOG</th>

Pharmacological Treatments for Acute Migraine

Study: Meta-analysis of 54 double-blind, placebo-controlled RCTs of pharmacologic treatment of acute migraine of moderate to severe intensity (21,022 patients in total).

Data Extraction: Number of patients, dosing regimens, details of study design, and timing or type of rescue medication. Outcomes include headache relief at 1 and 2 h, freedom from pain at 2 h, sustained relief for 24 h, and adverse effects within 24 h.

Main Results: Data were available for 9 oral medications, 2 intranasal medications, and subcutaneous sumatriptan. For H/A relief at 2 h, all interventions were effective except Cafergot®, with NNTs ranging from 2.0 for sumatriptan 6 mg SC to 5.4 for naratriptan 2.5 mg. The lowest NNT for oral medication was 2.6 for eletriptan 80 mg. For patients pain free at 2 h, the lowest NNT was 2.1 for sumatriptan 6 mg SC, with the lowest NNT for oral medication being 3.1 for rizatriptan 10 mg. For sustained relief over 24 h NNT ranged from 2.6 for eletriptan 80 mg to 8.3 for rizatriptan 5 mg. Side effects could not be analyzed systematically. There were no drug-to-drug comparisons.

Conclusion: Overall, most treatments were effective. Subcutaneous sumatriptan and ral triptans were most effective.

Elements of Sleep History
- Initiation of sleep
- Events prior to bed
- Lights
- Latency (estimated)
- Restless legs
- Hallucinations
- Maintaining sleep
- Number of wakeups/night
- Sleep walking/talking
- Snoring/gasping
- Dreams/nightmares
- Consequences of sleep
- Restorative
- Morning headache
- Falling asleep in inappropriate setting
Disturbances of Alertness and Sleep

Coma

- see Neurosurgery, NS35

Insomnia

- difficulty initiating or maintaining sleep, or waking up earlier than desired (leading to sleep that is chronically non-restorative/poor quality) despite adequate opportunity and circumstances for sleep

  - types
    - sleep state misperception, psychophysiologic insomnia (learned sleep-preventing associations – i.e. clock watching), fatal familial insomnia (rare prion protein mutation causing autonomic dysfunction), idiopathic (lifelong difficulty)
    - secondary causes
      - psychiatric disorders (80% of psychiatric patients): anxiety and depression (see Psychiatry, PS13)
      - neurologic disorders: neurodegenerative disease, epilepsy, neuromuscular disorders, many others
      - sleep disorders: restless legs syndrome (sleep initiation difficulties), sleep apnea (sleep maintenance difficulties)
      - medical conditions: pregnancy, cardiopulmonary (COPD/HF), GERD, pain (arthritis, fibromyalgia, cancer)
      - drugs/toxins: caffeine, alcohol, stimulants, antidepressants, glucocorticoids, sedative withdrawal

  - treatment
    - sleep log, sleep hygiene, stimulus control, sleep restriction, relaxation response, CBT

Sleep Apnea

- disorder of breathing in sleep associated with sleep disruption and consequent excessive somnolence (or drowsiness)

  - epidemiology
    - >2–4% of the population
    - correlated with obesity
    - significant morbidity: HTN, stroke, heart failure, sleepiness, mortality (accidents)

  - types
    - obstructive sleep apnea
    - central sleep apnea: no effort to breath over 10 s
    - mixed apnea: starts as central, but eventually becomes obstructive

  - etiology of central apnea: heart failure, opiates, brainstem pathology, myotonic dystrophy

  - etiology of obstructive apnea: collapse of airway due to low muscle tone in deep and REM sleep

  - diagnosis: apnea hypopnea index (AHI) or respiratory disturbance index (RDI) should be <5 in the normal state

  - treatment: conservative measures, dental devices, CPAP (common), surgery (rare), ensure driving safety

Restless Leg Syndrome (RLS) and Periodic Limb Movement in Sleep (PLMS)

- urge to move accompanied by uncomfortable sensations that begin or worsen with rest, are partially or totally relieved with movement, and are worse in evening/night; these features cannot be accounted for by another medical/behavioural condition

  - RLS refers to sensation

  - PLMS refers to the manifestation

  - epidemiology: 10% North Americans, 90% of RLS have PLMS, 50% of patients with PLMS have RLS

  - etiology: central (spasticity), peripheral nervous system (radiculopathy, neuropathy), pregnancy, iron deficiency, alcohol use

  - treatment
    - underlying contributors (iron and B12 supplementation), dopaminergic agonists (first line), clonazepam (causes tachyphylaxis), opioids (only exceptional circumstances)
    - NOT recommended: levodopa/carbidopa (Sinemet®), causes augmentation

Narcolepsy

- definition/clinical features: excessive daytime sleepiness (all narcolepsy), cataplexy = loss of muscle tone with emotional stimuli (pathognomonic) sleep paralysis (unable to move upon wakening), hypnagogic hallucinations (vivid dreams or hallucinations at sleep onset)

  - prevalence 1:2,000, onset in adolescence/early adulthood; life-long disorder

  - etiology: presumed autoimmune attack on orexin/hypocretin system, post head injury, MS, hypothalamic tumours; rarely familial

  - diagnosis: based on clinical history + multiple sleep latency test findings of short sleep latency <8 min and REM within 15 min of sleep onset on 2/4 naps

  - treatment
    - sleep hygiene and scheduled brief naps, restricted driving
    - alerting agents: modafinil (non-amphetamine stimulant), stimulant (i.e. methylphenidate)
    - anticitaplectic: TCAs, SSRIs, sodium oxybate

Drug Effects on Wakefulness and Sleep

- Antihistamines associated with increased sleepiness
- Stimulants increase arousal
- Caffeine (an adenosine antagonist) increases wakefulness
- Benzodiazepines reduce slow wave sleep
- Antidepressants (TCA/MAOI/SSRI) reduce REM, prolong REM latency
- Alcohol may hasten sleep onset but associated with increased arousals

Avoid sleep medications (especially in elderly patients) due to increased risk of falls, pseudodepression, and memory loss
Parasomnias
- **definition/clinical features**: unusual behaviours in sleep with clinical features appropriate to stage of sleep
- **etiology**: in elderly, REM sleep behaviour disorder may be associated with PD; in children, slow wave sleep arousals (sleep walking) may be associated with sleep disordered breathing
- **diagnosis**: clinical history in children, polysomnography in adults to exclude nocturnal seizures
- **treatment**: behavioural management (safety, adequate sleep); clonazepam for REM sleep behaviour tonsillectomy if appropriate in children

Circadian Rhythm
- **definition/clinical features**: abnormalities based on time of day rather than sleep (i.e. jet lag, shift work)
- **diagnosis**: clinical history

---

**CNS Infections**
- see Infectious Diseases, ID18

**Spinal Cord Syndromes**
- see Neurosurgery, NS29

---

**Stroke**

**Terminology**
- **stroke**: sudden onset of neurological deficits of a vascular basis with infarction of CNS tissue
  - infarction is permanent tissue injury (confirmed by neuroimaging)
- **TIA**: sudden onset of neurological deficits of a vascular basis without infarction (i.e. no imaging evidence of stroke)
  - may present with amaurosis fugax (transient monocular painless vision loss)

**Pathophysiology**
- two major types: ischemic (~80%) and hemorrhagic (~20%)

1. ischemic
   - arterial thrombosis: thrombus formation in artery (local/in situ)
     - large vessel: stenosis or occlusion of the internal carotid artery, vertebral, or intracranial arteries
       - mechanism: insufficient blood flow beyond lesion (hemodynamic stroke)
       - underlying processes: atherosclerosis (most common cause), dissection, and vasculitis
     - small vessel/lacunar
       - mechanism: chronic HTN and DM cause vessel wall thickening and decreased luminal diameter
       - affects mainly small penetrating arteries (primarily basal ganglia, internal capsule, and thalamus)
   - cardioembolic: blockage of cerebral arterial blood flow due to particles originating from a cardiac source
     - atrial fibrillation (most common), rheumatic valve disease, prosthetic heart valves, recent MI, fibrous and infectious endocarditis
   - systemic hypoperfusion (global cerebral ischemia)
     - inadequate blood flow to brain, usually secondary to cardiac pump failure (e.g. cardiac arrest arrhythmia, or MI)
     - primarily affects watershed areas (between the major cerebral arterial territories)

2. hemorrhagic
   - intracerebral hemorrhage
     - mechanisms
       - hypertensive (most common); rupture of small microaneurysms (Charcot-Bouchard aneurysms) causing intraparenchymal hemorrhage; most common sites: putamen, thalamus, cerebellum, andpons
       - other: trauma, amyloid angiopathy (associated with lobar hemorrhage), vascular malformations, vasculitis, drug use (cocaíne or amphetamines)
   - subarachnoid hemorrhage see Neurosurgery, NS18

---

**Hypertension Encephalopathy**
Acute severe HTN (typically dBP >130 or sBP >200) can cause hypertensive encephalopathy – abnormal fundoscopic exam (papilledema, hemorrhages, exudates, cotton-wool spots), focal neurologic symptoms, N/V, visual disturbances, and change in LOC

Consider transfer of acute stroke patient to a designated stroke centre for neuroprotective or thrombolytic therapy if the patient is seen in first few hours

Early seizure activity occurs in 5-25% of patients after ICH

Cerebral venous sinus thrombosis should be considered in the differential diagnosis of stroke and headache. It is an uncommon cause of either, but is associated with high morbidity and mortality. Patients often present with headache alone, but can also have seizures, focal neurological deficits, or cranial nerve palsies. This is diagnosed with MRV or CTV. Treatment is typically anticoagulation with heparin initially, then transition to warfarin

20-40% of patients with ischemic stroke may develop hemorrhagic transformation within 1 wk after the initial infarction

Blood work should only delay treatment if: patient is on anticoagulants, low platelet count suspected, abnormal electrolytes suspected, or any bleeding abnormality suspected
**Stroke Syndromes According to Vascular Territory**

- **ACA**: contralateral leg paresis, sensory loss, cognitive deficits (e.g. apathy, confusion, and poor judgment)
- **MCA**: proximal occlusion involves
  1. contralateral weakness and sensory loss of face and arm
  2. cortical sensory loss
  3. may have contralateral homonymous hemianopia or quadrantanopia
  4. if dominant (usually left) hemisphere: aphasia
  5. if non-dominant (usually right) hemisphere: neglect
  6. eye deviation towards the side of the lesion and away from the weak side
- **PCA**
  1. contralateral hemianopia or quadrantanopia
  2. midbrain findings: CN III and IV palsy/pupillary changes, hemiparesis
  3. thalamic findings: sensory loss, amnesia, decreased level of consciousness
  4. if bilateral: cortical blindness or prosopagnosia
  5. hemiballismus
- **basilar artery**
  - proximal (usually thrombosis): impaired EOM, vertical nystagmus, reactive miosis, hemi- or quadriplegia, dysarthria, locked-in syndrome, coma
  - distal (usually embolic, i.e. top of the basilar syndrome): somnolence, memory and behaviour abnormalities, oculomotor deficit
- **PICA (lateral medullary or Wallenberg syndrome)**: ipsilateral ataxia, ipsilateral Horner’s, ipsilateral facial sensory loss, contralateral limb impairment of pain and temperature sensation, nystagmus, vertigo, nausea/vomiting, dysphagia, dysarthria, hicups
- **medial medullary infarct** (anterior spinal artery, which can be associated with anterior cord infarct): contralateral hemiparesis (facial sparing), contralateral impaired proprioception and vibration sensation, ipsilateral tongue weakness
- **lacunar infarcts** (deep hemispheric white matter; involving deep penetrating arteries of MCA, circle of Willis, basilar, and vertebral arteries)
  - pure motor hemiparesis (posterior limb of internal capsule): contralateral arm, leg, and face
  - pure sensory loss (ventral thalamic): hemisensory loss
  - ataxic hemiparesis (ventral pons or internal capsule): ipsilateral ataxia and leg paresis
  - dysarthria-clumsy hand syndrome (ventral pons or genu of internal capsule): dysarthria, facial weakness, dysphagia, mild hand weakness and clumsiness

---

**Cortical Vascular Territories: Left Hemisphere**

- Area of anterior cerebral artery
- Area of middle cerebral artery
- Area of posterior cerebral artery

**Cortical Vascular Territories: Ventral Surface**

- Area of anterior cerebral artery
- Area of middle cerebral artery
- Area of posterior cerebral artery

---

Figure 25. Vascular territories
Assessment and Treatment of Ischemic Stroke

General Assessment
- ABCs, full vital sign monitoring, capillary glucose (Accu-Chek®), urgent CODE STROKE if <4.5 h from symptom onset (for possible thrombolysis)
- level of consciousness (knows age, month, obeys commands), dysarthria, dysnomia (cannot name objects)
- gaze preference, visual fields, facial palsy
- arm drift, leg weakness, ataxia
- sensation to pinprick, extinction/neglect
- history
  - onset: time when last known to be awake and symptom free
  - mimics to rule out: seizure/post-ictal, hypoglycemia, migraine, conversion disorder
- investigations
  - non-contrast CT head (STAT): to rule out hemorrhage and assess extent of infarct
  - ECG: to rule out atrial fibrillation (cardioembolic cause)
  - carotid dopplers, echocardiogram
  - CBC, electrolytes, creatinine, PT/INR, blood glucose, lipid profile
- imaging (i.e. CT ± MR or CT angiography) signs of stroke
  - loss of cortical white-grey differentiation
  - sulcal effacement (i.e. mass effect decreases visualization of sulci)
  - hypodensity of parenchyma
  - insular ribbon sign
  - hyperdense MCA sign

ACUTE STROKE MANAGEMENT

1. Thrombolysis
   - rtPA (recombinant tissue plasminogen activator)
   - given within 4.5 h of acute ischemic stroke onset provided there are clinical indications and no contraindications to use
   - indications and contraindications (see sidebar)

2. Anti-Platelet Therapy
   - give at presentation of TIA or stroke if rtPA not received
   - antiplatelet agents
     - ASA: recommended dose 81 mg chewed
     - if patient intolerant to ASA, use other antiplatelet agent (i.e. clopidogrel)

3. Acute Anti-Coagulant Therapy
   - for patients with TIA or stroke and atrial fibrillation, if rtPA not received:
     - recommend IV heparin (or ensuring INR between 2-3 if already anticoagulated on warfarin)
     - may delay initiation of oral anticoagulation depending on size of infarct and presence of petechial/frank hemorrhage

4. Intra-arterial Thrombectomy by Interventional Radiology
   - early thrombectomy improves outcomes in ischemic stroke with large artery occlusions of the proximal anterior circulation

Other Acute Management Issues
- avoid hyperglycemia which can increase the infarct size
- lower temperature if febrile (febrile stroke: think septic emboli from endocarditis)
- prevent complications
  - INO if dysphagia (to be reassessed by SLP)
  - DVT prophylaxis if bed-bound
  - initiate rehabilitation early

Blood Pressure Control
- do NOT lower the blood pressure unless the HTN is severe
- antihypertensive therapy is withheld for 48-72 hr (permissive hypertension) after thromboembolic stroke unless sBP >220 mmHg or dBP >120 mmHg, or in the setting of acute MI, renal failure, aortic dissection (IV labetalol first-line if needed)
- acutely elevated BP is necessary to maintain brain perfusion to the ischemic penumbra
- most patients with an acute cerebral infarct are initially hypertensive and their BP will fall spontaneously within 1-2 d

Etiological Diagnosis
- further investigations
  - additional neuroimaging (MRI)
  - vascular imaging: CTA/MRA/carotid dopplers
  - cardiac tests: echocardiogram, Holter monitoring
  - correct etiological diagnosis is critical for appropriate secondary prevention strategies
Primary and Secondary Prevention of Ischemic Stroke

Anti-Platelet Therapy
- primary prevention
  - no firm evidence for a protective role for antiplatelet agents for low-risk patients without a prior stroke/TIA
- secondary prevention
  - initial choice: ASA
  - if cerebrovascular symptoms while on ASA or if unable to tolerate ASA: Aggrenox® (ESPRIT trial), clopidogrel (CAPRIE trial)

Carotid Stenosis
- primary prevention (asymptomatic)
  - carotid endarterectomy is controversial: if stenosis >60%, risk of stroke is 2% per yr; carotid endarterectomy reduces the risk of stroke by 1% per yr (but 5% risk of complications)
- secondary prevention (previous stroke/TIA in carotid territory)
  - carotid endarterectomy clearly benefits those with symptomatic severe stenosis (70-99%), and is less beneficial for those with symptomatic moderate stenosis (50-69%) (NASCET trial), see Vascular Surgery VS6
  - according to the CREST trial, endarterectomy and carotid stenting have similar benefits in a composite endpoint of reduction of stroke, MI, and death; however, in the periprocedural period, stenting results in a higher rate of stroke, while endarterectomy results in a higher rate of MI

Atrial Fibrillation
- primary and secondary prevention with anticoagulation
  - classical risk stratification used CHADS2 score (0-6), but Stroke 2014 guidelines recommend that virtually all patients with atrial fibrillation without contraindication be anticoagulated
  - 0 (low risk, 1.9% annual stroke risk): antplatelet
  - 1 (intermediate risk, 2.8% annual stroke risk): anticoagulant or antplatelet – patient specific decision
  - >2 (high risk, 4-18.2% annual stroke risk): anticoagulant
- anticoagulation therapy
  - warfarin (ti rate to INR 2-3)
  - dabigatran (110 or 150 mg PO bid), apixaban (2.5 or 5 mg PO bid) or rivaroxaban (15 or 20 mg PO daily) may be alternatives to warfarin, but should be used cautiously; Praxbind reversal agent for dabigatran if necessary

Hypertension
- primary prevention
  - targets: BP <140/90 (or <130/80 for diabetics or renal disease); high risk but without diabetes, target sBP < 120 (SPRINT trial)
  - ACEI: ramipril 10 mg PO OD is effective in patients at high risk for cardiovascular disease (HOPE trial)
- secondary prevention
  - ACEI and thiazide diuretics are recommended in patients with previous stroke/TIA (PROGRESS trial)

Hypercholesterolemia
- primary prevention
  - statins in patients with CAD or at high risk for cardiovascular events, even with normal cholesterol (CARE trial)
- secondary prevention
  - statins – high dose atorvastatin (SPARCL trial) but lower doses may be more appropriate if patient cannot tolerate high dose

Diabetes
- ideal management: HbA1c <7%, fasting blood glucose between 4 and 7

Smoking
- primary prevention: smoking increases risk of stroke in a dose-dependent manner
- secondary prevention: after smoking cessation, the risk of stroke decreases to baseline within 2-5 yr

Physical Activity
- beneficial effect of regular physical activity has a dose-related response in terms of intensity and duration of activity

Stroke Rehabilitation
- individualized based on severity and nature of impairment; may require inpatient program and continuation through home care or outpatient services
- multidisciplinary approach includes dysphagia assessment and dietary modifications, communication rehabilitation, cognitive and psychological assessments including screen for depression, therapeutic exercise programs, assessment of ambulation and evaluation of need for assistive devices, splints or braces, vocational rehabilitation

Conclusions
- The rate of periprocedural stroke, myocardial infarction, death, and subsequent ipsilateral stroke did not differ between carotid-artery stenosis patients treated with stenting or endarterectomy at 10 years of follow-up.
- There was no significant difference in outcomes of either primary composite endpoint (HR 1.10; 95% CI 0.83-1.44) or periprocedural event (HR 0.90; 95% CI 0.64-1.52) in patients treated with stenting or endarterectomy.
- Asymptomatic and symptomatic patients showed to significant between-group differences in other endpoint.
- The rates of periprocedural stroke, myocardial infarction, death, and subquent ipsilateral stroke did not differ between carotid-artery stenosis patients treated with stenting or endarterectomy at 10 years of follow-up.

Stroke risk stratification for patients with atrial fibrillation

CHADS2
- Stroke risk stratification for patients with atrial fibrillation
  - CHF (1 point)
  - HTN sBP >160 mmHg/treated HTN (1 point)
  - Age >75 yr (1 point)
  - DM (1 point)
- Prior Stroke or TIA (2 points)

ABCD2 Score
- To predict/identify individuals at high risk of stroke following TIA
  - Age: 1 point for age >60 yr
  - Blood pressure (at presentation): 1 point for HTN (>140/90 mmHg at initial evaluation)
  - Clinical features: 2 points for unilateral weakness, 1 point for speech disturbance without weakness
  - Duration of symptoms: 1 point for 10-59 min, 2 points for >60 min
  - DM: 1 point
  - Stroke risk: 0-3: low risk, 4-5: moderate risk, 6-7: high risk

Long-Term Results of Stenting vs. Endarterectomy for Carotid-Artery Stenosis

Purpose: To evaluate the evidence for endovascular intervention in the treatment of ischemic stroke.

Study: Systematic review and meta-analysis of 10 randomized-controlled trials of 2,925 patients testing the efficacy and safety of endovascular intervention in patients suffering acute, ischemic stroke in the anterior circulation versus medical therapy, including thrombolysis, alone.

Results: The 7 RCTs published or presented in 2015 were without significant heterogeneity and formed the basis for the analysis. The majority of patients (86%) received stent retrievers and experienced higher than expected rates of recanalization (>50%). Risk ratio for good functional outcomes was 1.56 (RR: 0.86-0.90) and 0.78 for mortality (RR: 0.89-0.90). There was a difference in symptomatic intracranial hemorrhage following therapy.

Conclusions: Endovascular therapy is safe and improves outcomes when added to medical care with thrombolysis when administered in the 6-6 hours of large vessel, anterior circulation occlusive stroke. A trend towards improved mortality exists with complete follow-up results of several key trials pending.
Cerebral Hemorrhage

- **Definition**: intracranial bleeding into brain tissue
- **Etiology**: head trauma, hemorrhagic stroke

**Investigations**
- general investigations: see Assessment and Treatment of Ischemic Stroke, N50
- further investigations
  - LP (if suspect subarachnoid hemorrhage despite negative CT)
  - may require cerebral angiogram if suspect aneurysm or AVM
  - if typical location for hypertensive hemorrhage, repeat CT head in 4-6 wk after hemorrhage has resolved to rule out an underlying lesion

**Treatment**
- medical
  - anti-hypertensives: no conclusive BP target ranges for managing ICH exist; 2010 AHA/ASA guidelines suggest that reducing sBP to as low as 140 mmHg with IV anti-hypertensives is safe and appropriate management (target sBP 140-160 systolic)
  - ICP lowering medical management (if necessary): see Neurosurgery, NS22
- surgical: see Neurosurgery, NS4

Neurocutaneous Syndromes

- see Pediatrics, P79

Multiple Sclerosis

**Definition**
- a chronic inflammatory disease of the CNS characterized by relapsing remitting, or progressive neurologic symptoms due to inflammation, demyelination, and axonal degeneration

**Clinical Patterns of MS**
- relapsing remitting (RRMS) 85%, primary progressive (PPMS) 10%, progressive relapsing (PRMS) 5%, secondary progressive (SPMS)
- benign MS (BMS): retrospective diagnosis made after 15 years of mild disease, with no evidence of worsening (functional ability and MRI)
- most RRMS goes on to become SPMS

**MS Variants**
- Devic's = neuromyelitis optica (NMO): severe optic neuritis and extensive transverse myelitis extending >3 vertebral segments (antibody positive)
- clinically isolated syndrome (CIS): single MS-like episode, which may progress to MS
- tumeformactive MS: solitary lesion >2 cm mimicking neoplasms on MRI
- fulminant MS (Marburg): rapidly progressive and fatal MS associated with severe axonal damage, inflammation, and necrosis
- pediatric MS: onset of MS before the age of 18
  - epidemiology: rare (1.35-2.5 per 100,000 children)
  - presentation: more likely to present with isolated optic neuritis, isolated brainstem syndrome or symptoms of encephalopathy compared to adults
  - course: 98% have RRMS
  - diagnosis and treatment similar to adult MS
  - differential diagnosis: in the setting of nonspecific CSF abnormalities and MRI evidence of white matter lesion, rule out ADEM, optic neuritis, transverse myelitis, neumyelitis optica, CNS malignancies, leukodystrophies, and mitochondrial disease
- acute disseminated encephalomyelitis (ADEM): monophasic demyelinating disorder with multifocal neurologic symptoms seen mainly in children often following infection or vaccination

**Etiology**
- genetic
  - polygenetic: the HLA DRB1 gene has been demonstrated to be a genetically susceptible area
  - 30% concordance for monozygotic twins, 2-4% risk in offspring of affected mother or father
- environmental
  - MS is more common in regions with less sun exposure and lower stores of vitamin D (Europe, Canada, US, New Zealand, SE Australia)
  - MS has also been linked to certain viruses (EBV is associated with MS)
Epidemiology
- onset 17-35 yr; F:M = 3:1
- PPMS occurs in an older population with F=M

Diagnosis for RRMS
- demonstration of both dissemination in time and space based on the revised McDonald criteria (2010)
  - dissemination in time: 2 or more attacks, simultaneous presence of asymptomatic gadolinium-enhancing and non-enhancing MRI lesions at any time, or a new T2 and/or gadolinium-enhancing lesion(s) on follow-up MRI
  - dissemination in space: ≥1 T2 lesions on MRI in at least 2 of the 4 CNS regions (periventricular, juxtacortical, infratentorial, or spinal cord) or developing a second attack that implicates a different CNS region

Clinical Features
- symptoms include numbness, visual disturbance (optic neuritis), weakness, spasticity, diplopia (e.g. INO), impaired gag, vertigo, bladder dysfunction
- Lhermitte's sign: flexion of neck causes electric shock sensation down back into limbs indicating cervical cord lesion
- Uthoff's phenomenon: worsening of symptoms (classically optic neuritis) in heat
- SPMS: classically weakness of legs in pyramidal distribution paired with cerebellar findings of arms (i.e. intention tremor)
- symptoms not commonly found in MS: visual field defects, aphasia, apraxia, progressive hemiparesis
- relapse: acute/subacute onset of clinical dysfunction that peaks from days to weeks, followed by remission with variable symptom resolution (symptoms must last at least 24 h)
- in RRMS, average 0.4 to 0.6 relapses/yr, but higher disease activity in 1st yr of disease

Investigations
- MRI: demyelinating plaques appear as hyperintense lesions on T2 weighted MRI, with active lesions showing enhancement with gadolinium
  - typical locations: periventricular, corpus callosum, cerebellar peduncles, brainstem, juxtacortical region, and dorsolateral spinal cord
  - Dawson's fingers: periventricular lesions extending into corpus callosum
  - cranial MRI is more sensitive than spinal MRI
- CSF: oligoclonal bands in 90%, increased IgG concentration
- evoked potentials (visual/auditory/somatosensory): delayed but well-preserved wave forms

Treatment
- acute treatment: methylprednisolone 1,000 mg IV daily x 3-7 d (no taper required); if poor response to corticosteroids may consider plasma exchange
- disease modifying therapy (DMT)
  - goals: decrease relapse rate, decrease progression of disability, slow accumulation of MRI lesions
  - first line: teriflunomide, interferon-β (injection: Betaseron®, Avonex®, Rebi®), glatiramer acetate (injection: Copaxone®), BG-12 (Tecfidera®)
  - second line: natalizumab (Tysabri®) (monthly IV infusion), fingolimod (Gilenya®)
  - increased risk of progressive multifocal leukoencephalopathy (PML)
  - CIS: early treatment with interferons may delay potential second attack
  - RRMS: DMT reduces rate of relapse by about 30%
  - PPMS/SPMS: no proven efficacy of DMTs
- symptomatic treatment
  - spasticity: baclofen, tizanidine, dantrolene, benzodiazepine, botulinum toxin
  - bladder dysfunction: oxybutynin
  - pain: TCA, carbamazepine, gabapentin
  - fatigue: amantadine, modafinil, methylphenidate
  - depression: antidepressant, lithium
  - constipation: high fibre intake, stool softener, laxatives
  - sexual dysfunction: sildenafil (Viagra®), tadalafil (Cialis®), vardenafil (Levitra®, Staxyn®)
- education and counselling: MS Society, support groups, psychosocial issues

Prognosis
- good prognostic indicators: female, young, RRMS, presenting with optic neuritis, low burden of disease on initial MRI, low rate of relapse early in disease
- PPMS: poor prognosis, higher rates of disability, poor response to therapy
## Common Medications

### Parkinson's Disease
- **Mechanism of Action/Class:** Dopamine precursor
- **Generic Name:** levodopa + carbidopa
- **Trade Name:** Sinemet®
- **Dosing:** Carbidopa 25 mg/levodopa 100 mg PO tid
  - Maximum 200 mg carbidopa and 2,000 mg levodopa per day
- **Indications:** Parkinson's disease
- **Side Effects:** Narrow-angle glaucoma, use of MAO inhibitor in last 14 d, history of melanoma or undiagnosed skin lesions
- **Contraindications:** Hypertension, hallucinations, dyskinesias in last 14 d, history of melanoma or undiagnosed skin lesions

### Migraine
- **Mechanism of Action/Class:** Triptan (selective 5-hydroxytryptamine receptor agonist)
- **Generic Name:** sumatriptan
- **Trade Name:** Imitrex®
- **Dosing:** 25-100 mg PO qm
  - Maximum 200 mg/d
- **Indications:** Migraine
- **Side Effects:** Vertigo, chest pain, flushing, sensation of heat, hypertension crisis, peripheral vascular disease, coronary artery vasospasm, aciael dist, nausea, vomiting.
- **Contraindications:** Active bleeding, gastrointestinal bleeding, e.g. itraconazole, ritonavir

### EPILEPSY
- **Mechanism of Action/Class:** Anticonvulsant
- **Generic Name:** valproic acid
- **Trade Name:** Depakene®
- **Dosing:** Start at 100-200 mg PO OD
  - Increase by 200 mg/d up to 800-1,200 mg/d
- **Indications:** Essential febrile convulsion, myoclonic seizures, absence seizures
- **Side Effects:** Drowsiness, H/A, unsteadiness, dizziness, N/V, skin rash, agranulocytosis/aplastic anemia (rare)

### Stroke Prevention in AF
- **Mechanism of Action/Class:** Anticoagulant (direct thrombin inhibitor)
- **Generic Name:** dabigatran
- **Trade Name:** Pradaxa®
- **Dosing:** 110 mg PO bid or 150 mg PO bid
  - Ccr <30 mL/min, significant hemostatic imporation or CNS lesions within 6 mo with high risk of bleeding
- **Side Effects:** Dyspnea, gastritis, bleeding

ICP/Volume Relationship

- Monro-Kellie Doctrine: the brain is encased in a rigid skull with constant intracranial volume consisting of CSF, blood and brain.
- the increase in one constituent will: 1) necessitate the redistribution of CSF, blood and/or brain and 2) increase ICP.
- compensatory mechanisms initially maintain a normal ICP.
- Compensatory reserve (spatial compensation): 60-80mL in young people, 100-140mL in elderly (largely due to cerebral atrophy)
  - immediate: egress of CSF through foramen magnum to spinal canal, displacement of venous blood from sinuses into jugular veins
- once compensation is exhausted, ICP rises exponentially:
  - late: displacement of arterial blood (decreased CPP) eventually leading to ischemia, increasing brain edema or expanding mass displaces parenchyma into compartments under less pressure and expanding mass (Table 3)
  - end: cessation of cerebral perfusion when ICP>MAP, cerebral herniation down into foramen magnum

Figure 5. ICP volume curve
Cerebral Blood Flow

- brain receives about 15% of cardiac output (~750 mL/min)
- CBF is the vital parameter for brain function and depends on cerebral perfusion pressure (CPP) and cerebral vascular resistance (CVR)
- CPP is dependent on the difference between mean arterial pressure (MAP) and Intracranial Pressure (ICP) (Normal CPP >50 mmHg)
- cerebral autoregulation: mechanism that maintains constant CBF despite changes in CPP, unless:
  - high ICP such that CPP <40 mmHg
  - MAP >150 mmHg or MAP <50 mmHg
  - increased CO₂ = increased CBF via vasodilation
  - O₂ <50 mmHg = increased CBF via vasodilation
  - brain injury: e.g. SAH, severe trauma

ICP Measurement

- normal ICP 10-15 mmHg for adult, 3-7 mmHg for child, 1-5 mmHg for infant; varies with patient position
  - moderate elevation >20 mmHg
  - severe elevation >40 mmHg

Acute Monitoring

- indications include: severe TBI (GCS <8) + abnormal CT; normal CT under some conditions
  - methods: “gold standard” is intraventricular catheter, (external ventricular drain (EVD)), is the most accurate method and allows therapeutic drainage of CSF. Non-invasive methods (including transcranial Doppler, CT/MRI, fundoscopy etc) fail to measure ICP accurately enough to be used as routine measurement techniques

Chronic Monitoring

- fibreoptic monitor (intraventricular, intraparenchymal, subdural), subarachnoid bolt (Richmond screw), and epidural monitor

Elevated ICP

Etiology

- increased intracranial pressure
  - intracranial mass (tumour, cyst)
  - cerebral edema
    - vasogenic: BBB compromised (meningitis, hypertensive encephalopathy, tumour, late ischemia)
    - cytotoxic: BBB intact (cell death in: early ischemia, brain injury, encephalitis, status epilepticus)
    - interstitial: transudation of CSF into peri-ventricular white matter in hydrocephalus
    - osmotic: osmotic gradient increases intracellular free H₂O (acute hyponatremia, hepatic encephalopathy)
  - other space occupying lesions: depressed skull fracture, foreign body, pus/empyema

- increased intracranial blood volume
  - space occupying blood: epidural and subdural hematomas, intraparenchymal and subarachnoid hemorrhages
  - venous obstruction (venous sinus thrombosis, superior vena cava syndrome, cor pulmonale, venous sinus compression)
  - impaired autoregulation (hypotension, HTN, brain injury, status epilepticus)
  - vasodilatation (increased pCO₂/decreased pO₂/decreased extracellular pH)
  - increased intracranial CSF volume
  - increased production (rare): choroid plexus papilloma
  - hydrocephalus: obstructive vs. non-obstructive (see Table 6)
  - idiopathic intracranial HTN (pseudotumour cerebri) – see Idiopathic Intracranial Hypertension, NS8

ICP Measurement

- normal ICP 10-15 mmHg for adult, 3-7 mmHg for child, 1-5 mmHg for infant; varies with patient position
  - moderate elevation >20 mmHg
  - severe elevation >40 mmHg

Acute Monitoring

- indications include: severe TBI (GCS <8) + abnormal CT; normal CT under some conditions
  - methods: "gold standard" is intraventricular catheter, (external ventricular drain (EVD)), is the most accurate method and allows therapeutic drainage of CSF. Non-invasive methods (including transcranial Doppler, CT/MRI, fundoscopy etc) fail to measure ICP accurately enough to be used as routine measurement techniques

Chronic Monitoring

- fibreoptic monitor (intraventricular, intraparenchymal, subdural), subarachnoid bolt (Richmond screw), and epidural monitor

Clinical Features

Table 3. Clinical Features of Elevated ICP

<table>
<thead>
<tr>
<th>Clinical Features</th>
<th>Acutely Elevated ICP</th>
<th>Chronic Progressive ICP Elevation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Headache</td>
<td>Both aggravated by stooping, coughing, straining. Morning headaches: vasodilatation due to increased CO2 with recumbency</td>
<td></td>
</tr>
<tr>
<td>Nausea and Vomiting</td>
<td>Present in both, though greater predilection in acutely elevated ICP</td>
<td></td>
</tr>
<tr>
<td>Level of Consciousness</td>
<td>Lethargy if ICP = dBP or midbrain compression</td>
<td>Irritability, inattentiveness. Normal or modestly reduced LOC, confusion</td>
</tr>
<tr>
<td>GCS</td>
<td>Significant decline in GCS</td>
<td>Can be unchanged or modestly decreased</td>
</tr>
<tr>
<td>Optic Disc Changes</td>
<td>Subtle changes suggesting papilledema (subtle elevations in disc margin, mild disc hyperemia ± retinal hemorrhages (may take 24-48 h to develop)</td>
<td>Obvious papilledema</td>
</tr>
<tr>
<td>Visual Changes</td>
<td>Less common. Often not affected initially, however visual obscurations, flickering or blurring can occur</td>
<td>Optic atrophy/blindness due to chronic papilledema Enlarged blind spot, if advanced → episodic constrictions of visual fields (“grey-outs” lasting ~20 min) Differentiate from papillitis (usually unilateral with decreased visual acuity)</td>
</tr>
<tr>
<td>Extra-Ocular Movements</td>
<td>Less common. CN VI palsy: due to long intracranial course, more sensitive to ICP changes and thus earlier sign of acutely increased ICP Often falsely localizing (causative lesion remote to nerve) Upward gaze palsy and sunset eyes (especially in children with obstructive hydrocephalus)</td>
<td>Often full EDM</td>
</tr>
<tr>
<td>Herniation Syndromes</td>
<td>Often occur (see Table 4)</td>
<td>Present if acute on chronic presentation</td>
</tr>
<tr>
<td>Neurologic Deficits</td>
<td>Focal deficits present</td>
<td>Focal deficits can be present</td>
</tr>
</tbody>
</table>

Investigations
- patients with suspected elevated ICP require an urgent CT/MRI to identify etiology, assess for midline shift/herniation
- ICP monitoring where appropriate

Table 4. Herniation Syndromes

<table>
<thead>
<tr>
<th>Herniation Syndrome</th>
<th>Definition</th>
<th>Etiology</th>
<th>Clinical Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Subfalcine</td>
<td>Cingulate gyrus herniates under falx</td>
<td>Lateral supratentorial lesion</td>
<td>Usually asymptomatic Warnings of impending transtentorial herniation Risk of ACA compression</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2. Central Tentorial (Axial)</td>
<td>Displacement of diencephalon through tentorial notch</td>
<td>Supratentorial midline lesion Diffuse cerebral swelling Late uncatal herniation</td>
<td>Small pupils, moderately dilated, fixed (rostral to caudal deterioration), sequential failure of diencephal, medulla Decreased LOC (midbrain compression), EOM/upward gaze impairment (“sunset eyes”): compression of pretectum and superior colliculi (Patinaud’s syndrome) Risk of PCA compression Branstern (Duret) hemorrhage: secondary to shearing of basilar artery perforating vessels Diabetes insipidus (infection on pituatory stalk and hypothalamus), end-stage sign</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3. Lateral Tentorial (Uncal)</td>
<td>Uncus of temporal lobe herniates through tentorial notch</td>
<td>Lateral supratentorial lesion (often rapidly expanding traumatic hematoma)</td>
<td>Ipsilateral non-reactive dilated pupil (earliest, most reliable sign) + ipsilateral EON paralysis, ptoxis (CN III compression) Decreased LOC (midbrain compression) Risk of PCA compression Contralateral hemiplegia ± extensor (upgoing) plantar response = ipsilateral hemiplegia (“Kernohan’s notch” – a false localizing sign resulting from pressure from the edge of the tent rium on the contralateral cerebral peduncle)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>4. Upward</td>
<td>Cerebellar vermis herniates through tentorial incisura</td>
<td>Posterior fossa mass, brainstem or cerebellar infarction, exacerbated by ventriculostomy or VP shunt</td>
<td>Cerebellar infa ct (superior cerebellar artery [SCA] compression) Hydrocephalus (cerebral/sylvian aqueduct compression)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>5. Tonsillar</td>
<td>Cerebellar tonsils herniates through foramen magnum</td>
<td>Infratentorial lesion Following central tentorial herniation Following LP in presence of intracranial mass lesion</td>
<td>Neck stiffness and head tilt (tonsillar impaction) Decreased LOC (midbrain compression) Flaccid paralysis Respiratory irregularities, respiratory arrest (compression of medulary respiratory centres) Blood pressure instability (compression of medulary cardiovascular centres)</td>
</tr>
</tbody>
</table>

Figure 7. Herniation types

Blood Brain Barrier
- Glucose and amino acids cross slowly Non-polar/lipids cross fast
- Infection/neopasm → destroy tight junctions → vasogenic edema

Cushing’s Triad of Acute Raised ICP
- Hypertension
- Bradycardia (late finding)
- Irregular respiratory pattern

Papilledema
- Optic disc swelling with blurred margins (most commonly bilateral)
- Larger blind spot
Treatment of Elevated ICP

- treatment principle: treat primary etiology (i.e. remove mass lesions, ensure adequate ventilation for example in ARDS)
- if elevated ICP persists following treatment of primary cause, consider therapy when ICP >20 mmHg
targets: ICP <20 mmHg, CPP >65 mmHg, MAP >90 mmHg

Table 5. Management of Elevated ICP

<table>
<thead>
<tr>
<th>Consideration</th>
<th>Intervention</th>
<th>Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Conservative Measures</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Position</td>
<td>Elevate head of bed at 30° Maintain neck in neutral position</td>
<td>Increases 1. jugular venous patency 2. intracranial venous outflow with minimal effect on MAP</td>
</tr>
<tr>
<td>Fever Management</td>
<td>Acetaminophen or mechanical cooling</td>
<td>Decrease metabolic demands to decrease CBF and minimize brain injury</td>
</tr>
<tr>
<td>Prevent Hypotension</td>
<td>PRN: fluid, vasopressors, dopamine, norepinephrine</td>
<td>Maintains CBF</td>
</tr>
<tr>
<td>Normocarbia</td>
<td>Ventilate to pCO₂ 35-40 mmHg</td>
<td>Prevents vasodilatation</td>

</tbody>
</table>

Idiopathic Intracranial Hypertension (Pseudotumour Cerebri)

**Definition**
- raised ICP with papilledema, but without: mass, hydrocephalus, infection, or hypertensive encephalopathy (diagnosis of exclusion)

**Etiology**
- unknown (majority), but associated with:
  - dural sinus thrombosis
  - habitus/diet: obesity, hypervitaminosis A
  - endocrine: reproductive age, menstrual irregularities, Addison’s/Cushing’s disease
  - hematologic: iron deficiency anemia, polycythemia vera
  - drugs: steroid withdrawal, tetracycline, amiodarone, lithium, nalidixic acid, oral contraceptive
  - risk factors overlap with those of venous sinus thrombosis; similar to those for gallstones ("fat, female, fertile, forties")

**Epidemiology**
- incidence: general population ~1-2/100,000 per year; obese women of childbearing age 19-21/100,000

**Clinical Features**
- symptoms: H/A in >90%, nausea, impaired vision, pulsatile intracranial noise, diplopia can occur with CN VI palsy
- signs: CN VI palsy can occur (otherwise no neurologic deficits), visual acuity and field deficits, papilledema, optic atrophy
Hydrocephalus

- for hydrocephalus in children, see Pediatric Neurosurgery, NS36

Definition
- accumulation of excess CSF in the brain, functionally divided into obstructive and communicating
  - flow of CSF: produced by choroid plexus, lateral ventricles → foramen of Monroe → 3rd ventricle → cerebral/sylvian aqueduct → 4th ventricle → foramina of Luschka (lateral) and Magendie (medial) → subarachnoid space where CSF is re-absorbed by arachnoid villi/granulations into dural venous sinuses

Classification

<table>
<thead>
<tr>
<th>Disorder</th>
<th>Definition</th>
<th>Etiology</th>
<th>Findings on CT/MRI</th>
</tr>
</thead>
<tbody>
<tr>
<td>Obstructive (Non-Communicating) Hydrocephalus</td>
<td>CSF Circulation blocked within ventricular system proximal to the arachnoid granulations</td>
<td>Acquired Aqueductal Stenosis: adhesions after infection, hemorrhage; gliosis, tumor (e.g. medulloblastoma)</td>
<td>Ventricular enlargement proximal to block (enlarged temporal horns, ballooning frontal and/or occipital horns, enlarged 3rd → 4th ventricles)</td>
</tr>
<tr>
<td>Non-Obstructive (Communicating) Hydrocephalus</td>
<td>Most commonly CSF absorption blocked at extraventricular site = arachnoid granulations, rarely CSF absorption is overwhelmed by increased production</td>
<td>Intraventricular lesions: tumours, e.g. 3rd ventricle colloid cyst, hematoma Mass causing tentorial herniation causing aqueduct/4th ventricle compression Others: neurosarcoidosis, abscess/ granulomas, arachnoid cysts</td>
<td>Ventricular enlargement → normal pressure hydrocephalus</td>
</tr>
<tr>
<td>Normal Pressure Hydrocephalus (NPH)</td>
<td>Persistent ventricular dilatation in the context of normal CSF pressure</td>
<td>Idiopathic (50%) Others: subarachnoid hemorrhage, meningitis, trauma, radiation-induced</td>
<td>Enlarged ventricles without increased prominence of cerebral sulci</td>
</tr>
<tr>
<td>Hydrocephalus Ex Vacuo</td>
<td>Ventricular enlargement resulting from atrophy of surrounding brain tissue</td>
<td>Normal aging Degenerative dementias see Neurology, N23 (Alzheimer’s, Frontal Temporal, Creutzfeldt-Jacob Disease)</td>
<td>Enlarged ventricles and sulci Cerebral atrophy</td>
</tr>
</tbody>
</table>

Etiology
- impaired CSF dynamics
  - obstruction of CSF flow
  - decreased CSF absorption
  - increased CSF production (rarely in choroid plexus papilloma – 0.4-1% of intracranial tumours)
- congenital and acquired causes

Investigations
- MRI-brain (with and without contrast): slit like ventricles and distended perioptic subarachnoid space, but otherwise normal
- rule out: venous sinus thrombosis, mass, infection, hydrocephalus
- LP findings: opening pressure >20 mm H2O
- normal CSF analysis
- ophthalmologic: fields, acuity, papilledema

Treatment
- lifestyle change: encourage weight loss, fluid/salt restriction
- pharmacotherapy: acetazolamide (decreases CSF production), thiazide diuretic, or furosemide; discontinue offending medications
- surgery: if above fail → serial LPs, shunts, optic nerve sheath decompression (if progressive impairment of visual acuity)
- long term: 2 yr follow-up, repeat imaging to rule out occult tumour, ophthalmology follow-up
Epidemiology

- Estimated prevalence 1-1.5%; incidence of congenital hydrocephalus ~1-2/1,000 live births

Clinical Features

- Acute hydrocephalus: signs and symptoms of acutely elevated ICP (see Table 3)
- Chronic/gradual onset hydrocephalus: (weeks to months) (i.e. NPH) presents with a classic triad (Hakim’s Triad)
  - Ataxia (magnetic gait) + apraxia (pressure of ventricle on lower extremity motor fibres → gait disturbance)
  - Incontinence (pressure on cortical bowel/bladder centre)
  - Dementia (pressure on frontal lobes)

Investigations

- Imaging
  - CT/MRI findings (see Table 6)
  - Ultrasound (through anterior fontanelle in infants): ventriculomegaly, size and location of lesions (e.g. IVH)
  - Mantle radiosonde cisternography can test CSF flow and absorption rate (unreliable)
- ICP monitoring (e.g. LP, EVD) may be used to investigate NPH and test response to shunting (lumbar tap test)

Treatment

- External ventricular drain (EVD)
- Intermittent LPs for transient communicating hydrocephalus (SAH, IVH in premature infants)
- Surgical: surgical removal of obstruction (if possible) or excision of choroid plexus papilloma
- Eliminating obstruction (i.e. excision of mass, posterior fossa decompression for Chiari Malformation)
- Endoscopic
  - Endoscopic third ventriculostomy (ETV) ± choroid plexus cauterization (for obstructive hydrocephalus)
  - Endoscopic placement of aqueductal stent
- Shunt
  - Ventriculoperitoneal (VP): most common shunt
  - Ventriculopleural (VPl)
  - Ventriculoatrial (VA)
  - Lumboperitoneal: for communicating hydrocephalus and pseudotumour cerebri

Shunt Complications

CNS Tumours

Classification
- primary vs. metastatic (e.g. primary in breast, lung), intra-axial (parenchymal) vs. extra-axial, supratentorial vs. infratentorial, adult vs. pediatric
- benign: non-invasive, but can be devastating due to mass effect in fixed volume of skull (e.g. most meningiomas, WHO Grade I)
- malignant: implies rapid growth, invasiveness, possibly drop-metastases to spinal cord from a primary CNS tumour (rare)
- classification of nervous system tumours (* = most common) 
  - neuroepithelial
    - astrocytic tumours
      - oligoastrocytic tumours: oligoastrocytoma
      - neuronal and mixed neuronal glial tumours: ganglion cell tumours, cerebral neurocytomas
      - embryonal tumours: medulloblastoma, primitive neuroectodermal tumours (PNET)
      - other: pineal, ependymal, and choroid plexus tumours
  - meningeal: meningiomas*, mesenchymal, hemangioblastomas
  - cranial and paraspinal nerves: schwannoma, neurofibroma
  - lymphomas and hematopoietic: primary CNS lymphoma, plasmacytoma
  - germ cell: germinomas, teratomas, choriocarcinomas
  - sellar region: craniopharyngiomas, spindle cell oncocytoma, pituitary adenomas*
  - cysts: epidermoid/dermoid cysts, colloid cysts
  - local extension: chordomas, glomus jugulare tumours
  - metastatic tumours: lung*, breast*

Familial Syndromes Associated with CNS Tumours
- see Medical Genetics, MG7

Investigations
- CT, MRI, stereotactic biopsy (tissue diagnosis and molecular markers for prognosis), metastatic workup, tumour markers (i.e. germ cell tumours)

Treatment
- conservative: serial Hx, Px, imaging for slow growing/benign lesions
- medical: corticosteroids to reduce ICP, cytotoxic cerebral edema, pharmacologic (i.e. pituitary adenoma)
- surgical: total or partial excision (decompressive, palliative), shunt if hydrocephalus
- radiotherapy: conventional fractionated radiotherapy (XRT), stereotactic radiosurgery (e.g. Gamma Knife*)
- chemotherapy: e.g. alkylating agents (i.e. temozolomide (GBM)*, vincristine, cyclophosphamide, etc.)
Table 8. Tumour Location: Etiology and Clinical Presentation

<table>
<thead>

<td>Metastasis Acoustic neuroma (schwannoma) (5-10%) Hemangioblastoma (2%) Meningioma</td>
</tr>
</tbody>
</table>

Clinical Presentation

**Shared Features** (from elevated ICP)
- Headache: usually worse in AM and made worse with straining, coughing
- Nausea/Vomiting
- Papilledema
- Diplopia: CN VI palsy

**Distinguishing Features**
- Seizure: commonly the first symptom
- Progressive neurological deficits (70%)
- Frontal lobe: hemiparesis, dysphasia, personality changes, cognitive changes
- Temporal lobe: auditory/olfactory hallucinations, memory deficits, contralateral superior quadrantanopsia
- Mental Status Change: depression, apathy, confusion, lethargy
- “Tumour TIA” - stroke like symptoms caused by a) occlusion of vessel by tumour cells b) hemorrhage c) 2nd to "steal phenomenon" - blood is shunted from ischemic regions to non-ischemic regions
- Endocrine disturbance - with pituitary tumours (see Endocrinology, E19)
- Brainstem involvement: cranial nerve deficits and long tract signs
- Nausea/Vomiting: compression on vagal nucleus/area postrema
- Diplopia: direct compression CN VI
- Vertigo
- Nystagmus
- Truncal Ataxia + Titubation: cerebellar vermis lesions
- Limb Ataxia, dysmetria, intention tremor: cerebellar hemisphere lesions
- Obstructive hydrocephalus more common than supratentorial lesions

Metastatic Tumours

**Brain Metastasis**
- most common intra-cranial tumour in adults (~50% of all brain tumours)
- afflict ~25% of patients with any cancer
- hematogenous spread most common
- 80% are hemispheric, often at grey-white matter junction or temporal-parietal-occipital lobe junction
- likely emboli spreading to terminal MCA branches

**Investigations**
- identify primary tumour
  - full metastatic workup (CXR, CT chest/abdo, abdominal U/S nuclear medicine scan/PET, mammogram)
  - CT with contrast → round, well-circumscribed, often ring enhancing, ++ edema, often multiple
  - MRI more sensitive, especially for posterior fossa
  - consider biopsy in unusual cases or if no primary tumour identified

**Treatment**
- medical
  - phenytoin (or levetiracetam) for seizure prophylaxis if patient presents with seizure
  - dexamethasone to reduce edema given with ranitidine
  - chemotherapy (e.g. small cell lung cancer), but difficult delivery across BBB
- radiation
  - stereactic radiosurgery (highly focused fraction of radiation targeted to tumour): for discrete, deep-seated/inoperable tumours
  - multiple lesions: use WBRT; consider stereactic radiosurgery if <3 lesions
  - post-operative adjuvant RT consideration
- surgical
  - single/solitary lesions: use surgery and radiation

**Prognosis**
- median survival without treatment once symptomatic is ~1 mo, with optimal treatment 6-9 mo. The disease-specific Graded Prognostic Assessment (Ds-GPA) is a useful prognostic index. Prognosis varies depending on primary tumour type and extent of systemic tumour burden
Astrocytoma

- most common primary intra-axial brain tumour, common in 4th-6th decades

Table 9. World Health Organization Astrocytoma Grading System

<table>

*IDH mutant WHO Gr II/III tumours have a better overall prognosis than IDH wild-type; following IDH stratification, the chromosomal 1p/19q codeletion has prognostic value in IDH mutated grade II-III gliomas after adjustment for tumour proliferation, age, and adjuvant treatment

Clinical Features

- sites: cerebral hemispheres >> cerebellum, brainstem, spinal cord
- symptoms: recent onset of new/worsening H/A, N/V, seizure, ± focal deficits or symptoms of increased ICP

Investigations

- CT/MRI with contrast: variable appearance depending on grade
  - hypodense on CT, hypointense on T1 MRI, hyperintense on T2 MRI
  - low grade: most do not enhance and have calcification on CT
  - high grade: most enhance with CT contrast dye/gadolinium, possibly with central necrosis (especially if IDH wildtype)

Treatment

- low grade diffuse astrocytoma
  - close follow-up, radiation, chemotherapy, and surgery all valid options
  - de-differentiation to more malignant grade; typically occurs faster when diagnosed after age 45
  - surgery: not curative, trend towards better outcomes
  - radiotherapy alone or post-operative prolongs survival (retrospective evidence)
  - chemotherapy: usually reserved for tumour progression

- high grade astrocytomas (anaplastic astrocytoma and GBM)
  - goal is to prolong "quality" survival
  - surgery
    - gross total resection: maximal safe resection + fractionated radiation with 2 cm margin + concomitant and adjuvant temozolomide
    - except: near end-of-life; or extensive brainstem, bilateral, or dominant lobe GBM involvement
    - awake craniotomy for tumours in 'eloquent' regions (e.g. speech and language regions or near motor strip)
  - stereotactic biopsy if resection not possible, followed by fractionated radiation with 2 cm margin
  - expectant (based on functional impairment – Karnofsky score <70; patient's/family's wishes)
  - chemotherapy: ~20% response rate, temozolomide (agent of choice); better response to temozolomide predicted by MGMT gene hypermethylation
  - multiple gliomas: WBRT ± chemotherapy

Meningioma

- most common primary intracranial tumour, arising from arachnoid membrane
- often calcified, may cause hyperostosis of adjacent bone (detectable on imaging)
- classically see Psammoma bodies ("meningocytic whorls") on histology
- location: 70% occur along the parasagittal convexity, falx cerebri, and sphenoid bone; other locations: tuberculum sellae, foramen magnum, olfactory groove, and CP angle

Clinical Features

- middle aged, slight female predominance (M:F = 1:1.8), high progesterone receptors (increase in size with pregnancy)
- many are asymptomatic and can be an incidental finding; when symptoms occur focal neurologic deficits specific to location, ± seizures, symptoms of increased ICP
- molecular changes: between 40-80% of meningiomas contain mutations in chromosome 22 (involved in suppressing tumour growth); some have extra copies of PDGFR and EGFR; some are associated with NF2, if presence of neurofibromatosis type 2
Investigations
- **CT with contrast**: homogeneous, densely enhancing, along dural border ("dural tail"), well circumscribed, usually solitary (10% multiple, likely with loss of NF2 gene/22q12 deletion)
- **MRI with contrast**: characterization of mass and provides a better assessment of the patency of dural venous sinuses
- **angiography**
  - most are supplied by external carotid feeders (meningeal vessels)
  - can assess venous sinus involvement, "tumour blush" commonly seen (prolonged contrast image)

Treatment
- **conservative management**: asymptomatic and/or non-progressive on CT/MRI – serial monitoring for interval growth changes
- **surgery**: curative if complete resection and indicated when symptomatic and/or documented growth on serial CT/MRI
- **endovascular**: embolization for highly vascularized, likely bloody, tumours to facilitate surgery
- **radiation**: SRS may be an option for lesions <3 cm partially occluding the superior sagittal sinus; SRS or XRT for non-resectable, recurrent atypical/malignant meningiomas

Prognosis
- >90% 5 yr survival, recurrence rate variable (often ~10–20%)
- depends on extent of resection
- Simpson’s classification: degree of surgical resection completeness with symptomatic recurrence

Vestibular Schwannoma (Acoustic Neuroma)
- slow-growing (average of 1-10 mm/yr), benign posterior fossa tumour (8-10% of tumours)
- arises from vestibular nerve of CN VIII in internal auditory canal, expanding into bony canal and cerebello-pontine angle (CPA)
- if bilateral, diagnostic of neurofibromatosis type II
- epidemiology: 1.5/100,000; all age groups affected, peaks at 4th-6th decades

Clinical Features
- **early clinical trial**: (tumour <2 cm) unilateral progressive hearing loss 98%, tinnitus, and disequilibrium (compression of CN VIII)
- **later clinical features**
  - tumour usually >2 cm: ootalgia, facial numbness + weakness, changes to taste (due to CN V and VII compression, respectively)
  - tumour usually >4 cm: ataxia, H/A, N/V, diplopia, cerebellar signs (due to brainstem compression; obstructive hydrocephalus)

Investigations
- MRI with gadolinium or T2 FIESTA sequence (>98% sensitive/species); CT with contrast 2nd choice
- audiogram, brainstem evoked potentials, calorics tests

Treatment
- expectant: serial imaging (CT/MRI q6mo) and audiometry if tumour is small, hearing is still preserved, high perioperative risk, or elderly patient
- radiation: stereotactic radiosurgery or fractionated radiotherapy
- surgery: if lesion >3 cm, brainstem compression, edema, hydrocephalus
- curable if complete resection (almost always possible)
- operative complications: CSF leak, meningitis, required shunt; CN V, VII, VIII dysfunction (proportional to tumour size; only significant CNVIII disability if bilateral)
- implica ion for testing of family members of NF2 mutation carrier

**Pituitary Adenoma**
- primarily from anterior pituitary, 3rd-4th decades, M=F; associated with MEN-1 syndrome
- incidence in autopsy studies approximately 20%
- classification
  - microadenoma <1 cm; macroadenoma ≥1 cm
  - endocrine active (functional/secretory) vs. inactive (non-functional)
  - most common functional: prolactinomas, adrenocorticotropic, growth-hormone producing
  - differential diagnosis: parasellar tumours (e.g. craniopharyngioma, tuberculum sellae meningioma), carotid aneurysm

Clinical Features
- mass effects
  - H/A
  - bitemporal hemianopia (compression of optic chiasm) hydrocephalus (3rd ventricle compression)
  - invasive adenomas: CN III, IV, V1, V2, VI palsy (cavernous sinus compression); proptosis and chemosis (cavernous sinus occlusion)
Cerebral Abscess

Definition
• pus in brain substance, surrounded by tissue reaction (capsule formation)

Etiology
• modes of spread: 10-60% of patients have no cause identified
• pathogens
  - Streptococcus (most common), often anaerobic or microaerophilic
  - Staphylococcus (penetrating injury)
  - Gram-negatives, anaerobes (Bacteroides, Fusobacterium)
  - in neonates: Proteus and Citrobacter (exclusively)
  - immunocompromised: fungi and protozoa (Toxoplasma, Nocardia, Candida albicans, Listeria monocytogenes, Mycobacterium, and Aspergillus)

Sources of Pus/Infection
• four routes of microbial access to CNS
  1. hematogenous spread: arterial and retrograde venous
    - adults: chest is #1 source (lung abscess, bronchiectasis, empyema)
    - children: congenital cyanotic heart disease with R to L shunt
    - immunosuppression (AIDS – toxoplasmosis)
  2. direct implantation (dural disruption)
    - trauma
    - iatrogenic (e.g. following LP, post-operative)
    - congenital defect (e.g. dermal sinus)
  3. contiguous spread (adjacent infection): from air sinus, naso/oropharynx, surgical site (e.g. otitis media, mastoiditis, sinusitis osteomyelitis, dental abscess)
  4. spread from PNS (e.g. viruses: rabies, herpes zoster)
• common examples
  - epidural abscess: in cranial and spinal epidural space, associated with osteomyelitis
    - treatment: immediate drainage and antibiotics, surgical emergency if cord compression
  - subdural empyema: bacterial/fungal infection, due to contiguous spread from bone or air sinus, progresses rapidly
    - treatment: surgical drainage and antibiotics, 20% mortality
  - meningitis, encephalitis (see Infectious Diseases, ID18)
  - cerebral abscess

endocrine effects (see Endocrinology, E15)
• hyperprolactinemia (prolactinoma): infertility, amenorrhea, galactorrhea, decreased libido
• ACTH production: Cushing’s disease, hyperpigmentation
• GH production: acromegaly/gigantism
• panhypopituitarism: due to compression of pituitary (hypothyroidism, hypoadrenalism, hypogonadism)
• diabetes insipidus (DI) – rare, except in apoplexy

pituitary apoplexy (sudden expansion of mass due to hemorrhage or necrosis)
• abrupt onset H/A, visual disturbances, ophthalmoplegia, reduced mental status, panhypopituitarism
  and DI
• CSF rhinorrhea and seizures (rare)
• signs and symptoms of subarachnoid hemorrhage (rare)

Investigations
• formal visual fields, CN testing
• endocrine tests (prolactin level, TSH, 8 AM cortisol, fasting glucose FSH/LH, IGF-1), electrolytes, urine electrolytes, and osmolarity
• imaging (MRI with and without contrast)

Treatment
• medical
  - for apoplexy: rapid corticosteroid administration ± surgical decompression
  - for prolactinoma: dopamine agonists (e.g. bromocriptine)
  - for Cushing’s: serotonin antagonist (cyproheptadine), inhibition of cortisol production (ketoconazole)
  - for acromegaly: somatostatin analogue (octreotide) ± bromocriptine
  - endocrine replacement therapy
• surgical
  - endoscopic trans-sphenoidal, trans-ethmoidal, and less commonly trans-cranial approaches (i.e. for significant suprasellar extension)
• post-operative concerns: DI, adrenal insufficiency (AI), CSF leak
  - DI and AI: AM cortisol serum sodium and osmolality, urine output and specific gravity (treatment AI: glucocorticoids; DI: desmopressin/DDAVP)
  - CSF rhinorrhea: test for β transferrin

Figure 14. Cavernous Sinus
Risk Factors
- lung abnormalities (infection, AV fistulas; especially Osler-Weber-Rendu syndrome [i.e. hereditary hemorrhagic telangiectasia])
- congenital coronary heart disease: R-to-L shunt bypasses pulmonary filtration of micro-organisms
- bacterial endocarditis
- penetrating head trauma
- immunosuppression (e.g. AIDS)
- dental abscess, poor dentition

Clinical Features
- focal neurological signs and symptoms
  - H/A, decreased LOC; hemiparesis and seizures in 50%
  - mass effect, increased ICP and sequelae (cranial enlargement in children)
  - hemiparesis and seizures in 50%
  - ± signs and symptoms of systemic infection (low-grade fever, leukocytosis)

Complications
- with abscess rupture: ventriculitis, meningitis, venous sinus thrombosis
- CSF obstruction
- transtentorial herniation

Investigations
- CT scan often first test in emergency department
- MRI
  - imaging of choice
  - apparent diffusion coefficient (ADC) used to differentiate abscess (black) from tumour (white)
  - WBC/ESR, may be normal, blood cultures rarely helpful and LP contraindicated if large mass
  - CSF: non-specific (high ICP, high WBC, high protein, normal carbohydrate), rarely helpful, usually negative culture

Treatment
- aspiration ± excision and send for Gram stain, acid fast bacillus (AFB), CandS, fungal culture
- excision preferable if location suitable
- antibiotics
  - empirically: vancomycin + ceftriaxone + metronidazole or chloramphenicol or rifampin (6-8 wk therapy)
  - revise antibiotics when C&S known
  - anti-convulsants (1-2 yr)
- follow-up CT is critical (do weekly initially, more frequent if condition deteriorates)

Prognosis
- mortality with appropriate therapy ~10%, permanent deficits in ~50%

### Recommendations for Duration of Antibiotic Therapy for Brain Abscesses

**Summary:**
1. Prudent period of 4-6 weeks of antibiotic therapy for surgically treated abscesses.
2. 6-8 weeks of IV treatment for abscesses treated medically only.
3. 6-8 weeks of IV treatment for multiple abscesses when larger ones are treated surgically.

**Methods:** Systematic literature search using MEDLINE database or studies during 1988-2008 to methodologically evaluate all studies pertaining to brain abscesses.

**Results:** Several recommendations were made by extracting evidence; for duration of antibiotic therapy, it was noted that IV antibiotic therapies were usually >4 weeks. No studies have evaluated the duration of antibiotic therapy on outcome.

Without evidence to safely evaluate endovenous therapy time, authors agreed with British Society for Antimicrobial Chemotherapy recommendations (see summary).
**Extradural (“Epidural”) Hematoma**

**Etiology**
- temporal-parietal skull fracture: 85% are due to ruptured middle meningeal artery; remainder of cases are due to bleeding from middle meningeal vein, dural sinus, or bone/diploic veins

**Epidemiology**
- young adult, M:F = 4:1; rare before age 2 or after age 60
- 1-4% of traumatic head injuries

**Clinical Features**
- classic sequence (seen in <30%); post-traumatic reduced LOC, a lucid interval of several hours, then obtundation, hemiparesis, ipsilateral pupillary dilatation, and coma
- signs and symptoms depend on severity but can include H/A, N/V, amnesia, altered LOC, aphasia, seizures, HTN, and respiratory distress
- deterioration can take hours to days

**Investigations**
- CT without contrast: “lenticular-shaped” usually limited by suture lines but not limited by dural attachments

**Treatment**
- admission, close neurological observation with serial CT indicated if all of the following are present
  - small volume clot, minimal midline shift (MLS <5 mm), GCS >8, no focal deficit
  - otherwise, craniotomy to evacuate clot, follow-up CT
- patients with initial EDH >10mL on CT within 2 hours or EDH in temporoparietal region are more likely to develop epidural hematoma enlargement and require close CT follow-up at 5-6 hr post impact
- mannitol pre-operative if elevated ICP or signs of brain herniation

**Prognosis**
- good with prompt management, as the brain is often not damaged
- worse prognosis if bilateral Babinski or decerebration pre-operative
- death is usually due to respiratory arrest from uncal herniation (injury to the midbrain)

**Subdural Hematoma**

**Table 11 Comparison of Epidemiology and Etiology of Acute and Chronic SDH**

<table>
<thead>
<tr>
<th></th>
<th>Acute SDH</th>
<th>Chronic SDH</th>

</thead>
<tbody>
<tr>
<td><strong>Time Course</strong></td>
<td>1-2 d after bleeding onset</td>
<td>≥15 d after bleeding onset</td>
</tr>
<tr>
<td><strong>Etiology</strong></td>
<td>Rupture of vessels that bridge the subarachnoid space (e.g. cortical artery, large vein, venous sinus) or cerebral laceration</td>
<td>Blood within the subdural space evokes an inflammatory response: Fibroblast invasion of clot and formation of neomembranes within days → growth of neocapillaries → fibrinolysis and liquefaction of blood clot (forming a hygroma) Course is determined by the balance of rebleeding from neomembranes and resorption of fluid</td>
</tr>
<tr>
<td><strong>Risk Factors</strong></td>
<td>Trauma, acceleration-deceleration injury, anticoagulants, alcohol, cerebral atrophy, infant head trauma</td>
<td>Older, alcoholics, patients with CSF shunts, anticoagulants, coagulopathies</td>
</tr>
<tr>
<td><strong>Clinical Features</strong></td>
<td>No lucid period, signs and symptoms can include: altered LOC, pupillary irregularity, hemiparesis</td>
<td>Often due to minor injuries or no history of injury May present with minor H/A, confusion, language difficulties, TIA-like symptoms, symptoms of raised ICP ≤ seizures, progressive dementia, gait problem Obtundation disproportionate to focal deficit; “the great imitator” of dementia, tumours</td>
</tr>
<tr>
<td><strong>Investigations</strong></td>
<td>CT: Hyperdense concave “crescentic” mass, crossing suture lines</td>
<td>CT: hypodense (liquefied clot), crescentic mass</td>
</tr>
<tr>
<td><strong>Treatment</strong></td>
<td>Craniotomy if clinically symptomatic, if hematoma &gt; 1 cm thick or if MLS &gt; 5 mm (optimal if surgery &lt; 4 h from onset Otherwise observe with serial imaging</td>
<td>Seizure prophylaxis only if post-traumatic seizure Reverse coagulopathies Burr hole drainage of liquefied clot indicated if symptomatic or thickness &gt; 1 cm; craniotomy if recurs more than twice</td>
</tr>
<tr>
<td><strong>Prognosis</strong></td>
<td>Poor overall since the brain parenchyma is often injured (mortality range is 50-90%, due largely to underlying brain injury) Prognostic factors: initial GCS and neurologica status, post-operative ICP</td>
<td>Good overall as brain usually undamaged, but may require repeat drainage</td>
</tr>
</tbody>
</table>

*Use Of Drains Vs. No Drains After Burr-Hole Evacuation For Treatment Of Chronic Subdural Hematoma*  
*Cochrane Database Syst Rev. 2016 Aug 31;(8):CD011402*  
**Summary**
- some evidence that post-operative drainage is effective in reducing the symptomatic recurrence of chronic subdural hematomas  
- The effect of drainage on the occurrence of surgical complications, mortality, and poor functional outcomes is uncertain due to low-quality evidence  
- No strong evidence of increase in complications when drains are used  
**Methods** comprehensive search strategy databases extracting 9 RCTs (n=989) comparing external subdural drains with no drains after burr-hole evacuation for treatment of chronic subdural hematomas  
**Results** significant reduction in the risk of recurrence with sub-dural drains (RR 0.45, 95% CI 0.32-0.61), no strong evidence of increase in complications (RR 0.70, 95% CI 0.71-1.32), mortality (RR 0.70, 95% CI 0.45-1.33), poor functional outcome (RR 0.68, 95% CI 0.44-1.05).
Cerebrovascular Disease

Ischemic Cerebral Infarction (80%)
- embolic, thrombosis of intracerebral arteries, vasculitis, hypercoagulability, etc. (see Neurology, N50)

Intracranial Hemorrhage (20%)
- SAH, spontaneous ICH, IVH

Subarachnoid Hemorrhage

Definition
- bleeding into subarachnoid space (intracranial vessel between arachnoid and pia)

Etiology
- trauma (most common)
- spontaneous
  - ruptured aneurysms (75-80%)
  - idiopathic (14-22%)
  - AVMs (4-5%)
- coagulopathies (iatrogenic or primary), vasculitides, tumours, cerebral artery dissections (<5%)

Epidemiology
- ~10 28/100,000 population/yr
- peak age 55-60, 20% of cases occur under age 45

Risk Factors
- HTN
- pregnancy/parturition in patients with pre-existing AVMs, eclampsia
- oral contraceptive pill
- substance abuse (cigarette smoking, cocaine, alcohol)
- conditions associated with high incidence of aneurysms (see Intracranial Aneurysms, NS20)

Clinical Features of Spontaneous SAH
- sudden onset (seconds) of severe “thunderclap” H/A usually following exertion and described as the “worst headache of my life” (up to 97% sensitive, 12-25% specific)
- N/V, photophobia
- meningismus (neck pain/stiffness, positive Kernig's and Brudzinski's sign)
- decreased LOC (due to either raised ICP, ischemia, seizure)
- focal deficits: cranial nerve palsies (CN III, IV), hemiparesis
- ocular hemorrhage in 20–40% (due to sudden raised ICP compressing central retinal vein)
- reactive HTN

Hunt and Hess Grade
(clinical grading scale for SAH)

Mortality of Grade 1-2, 20%, increased with grade

Hemorrhage in Older Patients with Extensive Middle-Cerebral-Artery Stroke
NEJM 2014;370:1091-1100

Purpose: To determine if early decompressive hemicraniectomy reduces mortality among patients >60 yr.

Study: 112 patients >60 yr (median age 70 yr) with malignant MCA infarction randomly assigned to conservative ICU treatment versus hemicraniectomy. Endpoint was survival without severe disability (modified Rankin scale score 0-4).

Results: The proportion of patients who survived without severe disability was 38% in the hemicraniectomy group and 18% in the control group (OR 2.91, 95% CI 1.06-7.49). Modified Rankin scale scores in hemicraniectomy versus control group in terms of percentages of patients: 0-2, 0%, 0% 3 or moderate disability (7%, 3%), 4 or moderate severe disability (32%, 15%), 5 or severe disability (28%, 13%) and 6 or death (33%, 7%). Infections were more frequent in the hemicraniectomy group and hemiation more frequent in the control group.

Conclusions: Hemicraniectomy increased survival without severe disability among patients >60 yr with a malignant MCA infarction.
sentinel bleeds
• represents undiagnosed SAH
• SAH-like symptoms lasting <1 d ("thunderclap H/A")
• may have blood on CT or LP
• ~30-60% of patients with full blown SAH give history suggestive of sentinel bleed within past 3 wk
• differential diagnosis: sentinel bleed, dissection/thrombosis of aneurysm, venous sinus thrombosis, benign cerebral vasculitis, benign exertional H/A

Investigations
• non-contrast CT – for diagnosis of SAH
  • 98% sensitive within 12 h, 93% within 24 h; 100% specificity
  • may be negative if small bleed or presentation delayed several days
  • acute hydrocephalus, IVH, ICH, infarct or large aneurysm may be visible
• lumbar puncture (highly sensitive) – for diagnosis of SAH if CT negative but high suspicion:
  • elevated opening pressure (>18 cm H2O)
  • bloody initially, xanthochromic supernatant with centrifugation ("yellow") by ~12 h, lasts 2 wk
  • RBC count usually >100,000/mm³ without significant drop from first to last tube (in contrast to traumatic tap)
  • elevated protein due to blood breakdown products
• four vessel cerebral angiography ("gold standard" for aneurysms)
  • demonstrates source of SAH in 80-85% of cases
  • angiogram negative SAH: repeat angiogram in 7–14 d, if negative → "perimesencephalic SAH"
• MRA and CTA: sensitivity up to 95% for aneurysms, CTA>MRA for smaller aneurysms and delineating adjacent bony anatomy

Non traumatic Subarachnoid Hemorrhage in the Setting of Negative Cranial Computed Tomography Results: External Validation of a Clinical and Imaging Prediction Rule

Background: Two rules for SAH diagnosis exist. A clinical prediction rule states that patients with acute severe H/A but without the clinical variables age >40 yr, neck pain, loss of consciousness, or onset of H/A with exertion are at low risk for SAH. An imaging prediction rule bases diagnosis on non-contrast cranial CT for patients within 6 h of H/A onset.

Methods: Matched case-control study of 55 patients at 21 emergency departments between 2000 and 2011, and diagnoses were verified by lumbar puncture.

Results: The clinical prediction rule for diagnosis of SAH was 97% sensitive, 22.7% specific, and had a negative likelihood ratio of 0.13. Using the imaging prediction rule resulted in a false negative rate of 21%.

Conclusions: Performing the clinical and imaging rules together has the potential for maximizing sensitivity of prediction and reducing rates of lumbar puncture, but using imaging alone can result in missed cases.

The Vasograde: A Simple Grading Scale For Prediction Of Delayed Cerebral Ischemia After Subarachnoid Hemorrhage
Stroke. 2015;46(7):1826-31

Background: Patients are classically at risk of delayed cerebral ischemia (DCI) after aneurysmal subarachnoid hemorrhage. We validated a grading scale—the VASOGRADE for prediction of DCI.

Method: We used data of 3 phase II randomized clinical trials and a single hospital series to assess the relationship between the VASOGRADE and DCI.

Results: In a cohort of 746 patients, the VASOGRADE significantly predicted DCI (P<0.001). The VASOGRADE-Yellow had a tendency for increased risk for DCI (odds ratio [OR], 3.1; 95% CI, 0.7–12.2) when compared with VASOGRADE-Green; those with VASOGRADE-Red had a high risk of DCI (OR, 3.1; 95% CI, 0.7–16.2).

Conclusions: The VASOGRADE results validated previously published risk charts in a large and diverse sample of subarachnoid hemorrhage patients, which a low DCI risk stratification on presentation after subarachnoid hemorrhage. It could help to select patients at high risk of DCI, as well as standardize treatment protocols and research studies.
Intracranial Aneurysms

**Prognosis**
- 10-15% mortality before reaching hospital, overall 50% mortality (majority within first 2-3 wk)
- 30% of survivors have moderate to severe disability
- a major cause of mortality is rebleeding, for untreated aneurysms:
  - risk of rebleed: 4% on first day, 15-20% within 2 wk, 50% by 6 mo
  - if no rebleed by 6 mo, risk decreases to same incidence as unruptured aneurysm (2%)
  - only prevention is early clipping or coiling of “cold” aneurysm
  - rebleed risk for “perimesencephalic SAH” is approximately same as for general population

**Epidemiology**
- prevalence 1-4% (20% have multiple)
- F>M; age 35-65 yr

**Types**
- saccular (berry)
  - most common type
  - located at branch points of major cerebral arteries (Circle of Willis)
  - 85-95% in carotid (anterior) system, 5-15% in vertebrobasilar (posterior) circulation
- fusiform
  - atherosclerotic
  - more common in vertebrobasilar system, rarely rupture
- infectious
  - secondary to any infection of vessel wall, 20% multiple
  - 60% *Streptococcus* and *Staphylococcus*
  - 3-15% of patients with bacterial endocarditis

**Complications**
- vasospasm: vasoconstriction and permanent pathological vascular changes in response to vessel irritation by blood – can lead to delayed cerebral ischemia and death
- onset: 4-14 d post-SAH, peak at 6-8 d; most commonly due to SAH, rarely due to ICH/IVH
- clinical features (new onset ischemic deficit): confusion, decreased LOC, focal deficit (speech or motor e.g. pronator drift)
- risk factors: large amount of blood on CT (high Fisher grade), smoking, increased age, HTN
- “symptomatic” vasospasm in 20-30% of SAH patients
- “radiographic” vasospasm in 30-70% of arteriograms performed 7 d following SAH
- diagnosed clinically, and/or with transcranial Doppler (increased velocity of blood flow)
- risk of cerebral infarct and death
- treatment
  - hyperdynamic (“triple H”) therapy using fluids and pressors, usually after ruptured aneurysm has been clipped/coiled
  - direct vasodilatation via angioplasty or intra-arterial verapamil for refractory cases
- delayed cerebral ischemia: neurological deterioration persisting more than 1 hour in the absence of any obvious contributing physiological, radiological or laboratory abnormalities
  - peaks 4-10 days post ictus
  - can progress to cerebral infarction and is associated with significant morbidity and mortality
  - mechanism behind DCI is unclear but includes vasospasm, vascular dysautoregulation, neurotoxic effects from the blood, inflammation, micro-thrombi and cortical spreading depolarizations
  - it is an essential target for SAH management
- hydrocephalus (15-20%): due to blood obstructing arachnoid granules
  - can be acute or chronic, requires extraventricular drain (EVD) or shunt, respectively
- neurogenic pulmonary edema
- hyponatremia: due to cerebral salt wasting (increased renal sodium loss and ECFV loss), not SIADH
- diabetes insipidus
cardiac: arrhythmia (>50% have ECG changes), MI, CHF

**Intracranial Aneurysms**
Risk Factors
• autosomal dominant polycystic kidney disease (15%)
• fibromuscular dysplasia (7-21%)
• AVMs
• connective tissue diseases (Ehlers-Danlos, Marfan)
• family history
• bacterial endocarditis
• Osler-Weber-Rendu syndrome (hereditary hemorrhagic telangiectasia)
• atherosclerosis and HTN

Trauma

Clinical Presentation
• rupture (90%), most often SAH, but 30% ICH, 20% IVH, 3% subdural bleed
• sentinel hemorrhage (“thunderclap H/A”) → requires urgent clipping/coiling to prevent catastrophic bleed
• mass effect (giant aneurysms)
  • internal carotid or anterior communicating aneurysm may compress:
    • the pituitary stalk or hypothalamic causing hypopituitarism
    • the optic nerve or chiasm producing a visual field defect
  • basilar artery aneurysm may compress midbrain, pons (limb weakness), or CN III
  • posterior communicating artery aneurysm may produce CN III palsy
  • intracavernous aneurysms (CN III, IV, V1, V2, VI)
• distal embolization (e.g. amaurosis fugax)
• seizures
• H/A (without hemorrhage)
• incidental CT or angiography finding (asymptomatic)

Investigations
CT angiogram (CTA), magnetic resonance angiography (MRA), cerebral angiogram

Treatment
• ruptured aneurysms
  • overall trend towards better outcome with early surgery or coiling (48-96 h after SAH)
  • treatment options: surgical placement of clip across aneurysm neck, trapping (clipping of proximal and distal vessels), thrombosing using Guglielmi detachable coils (coiling) or flow diversion stents, wrapping (last resort)
  • choice of surgery vs. coiling not yet well defined: consider location, size, and tortuosity of the aneurysm, patient comorbidities, age, and neurological condition; in general:
    • clipping: posterior > anterior circulation, deep/eloquent location, basilar artery bifurcation/apex, older age, presence of comorbidities, presence of vasospasm
    • coiling: superficial > deep, broad aneurysmal base branching arteries at the aneurysm base, tortuosity/atherosclerosis of afferent vessels, dissection, hematoma, acute brainstem compression
• unruptured aneurysms
  • average 1% annual risk of rupture: risk dependent on size and location of aneurysm
  • no clear evidence on when to operate: need to weigh life expectancy
  • risk of morbidity/mortality of SAH (20% 50%) vs. surgical risk (2%-5%)
  • generally treat unruptured aneurysms >10 mm
  • consider treating when aneurysm 7-9 mm in middle-aged, younger patients or patients with a family history of aneurysms
  • follow smaller aneurysms with serial angiography

Long-Term, Serial Screening for Intracranial Aneurysms in Individuals with a Family History of Aneurysmal Subarachnoid Hemorrhage: A Cohort Study
Lancet Neurol 2014; 13:385-392
Purpose: To examine the yield of long-term serial screening for intracranial aneurysms for individuals with a positive family history of aneurysmal subarachnoid hemorrhage (aSAH) (two or more first degree relatives who have had aSAH or unruptured intracranial aneurysms).

Study: Screening results from April 1 1993 to April 1 2013 were reviewed in a cohort study. MRA or CTA was done from age 16-18 to 65-70 yr. After a negative screen, individuals were advised to contact the clinic in 5 yr for follow-up.

Results: Aneurysms were identified in 11% of individuals at first screening (n=459), 8% at second screening (n=261), 5% at third screening (n=128), and 5% at fourth screening (n=84). Smoking (OR 2.7, 95% CI 1.2-5.9), history of previous aneurysms (3.9, 1.2-12.3), and familial history of aneurysms (3.5, 1.6-8.1) were significant risk factors for aneurysm at first screening. History of previous aneurysms was the only significant risk factor for aneurysms at follow-up screening (HR 4.5, 95% CI 1.1-18.7).

Conclusions: The benefit of long-term screening in individuals with a family history of aSAH is substantial up to and after 10 yr of follow-up and two initial negative screens.

The Unruptured Intracranial Aneurysm Treatment Score
Neurology 2015;85(10):881-9
Objective: to develop an unruptured intracranial aneurysm (UIA) treatment score (UIATS) model that includes and quantifies key factors involved in clinical decision making in the management of UIAs and to assess agreement for this model among specialists in UIA management and research.

Methods: An international multidisciplinary (neurosurgery, neuroradiology, neurology, clinical epidemiology) group of 69 specialists was convened to develop and validate the UIATS model using a Delphi consensus method.

Results: The UIATS accounts for 29 key factors in UIA management.

Conclusions: This novel UIA decision guidance study captures an excellent consensus among highly informed individuals on UIA management, irrespective of their underlying specialty.
Intracerebral Hemorrhage

Definition
- hemorrhage within brain parenchyma, accounts for ~10% of strokes
- can dissect into ventricular system (IVH) or through cortical surface (SAH)

Etiology
- HTN (usually causes bleeds at putamen, thalamus, pons, and cerebellum)
- hemorrhagic transformation (reperfusion post stroke, surgery, strenuous exercise, etc.)
- vascular anomalies
  - aneurysm, AVMs, and other vascular malformations (see Vascular Malformations, NS23)
  - venous sinus thrombosis
  - arteriopathies (cerebral amyloid angiopathy, lipohyalinosis, vasculitis)
- tumors (1%): often malignant (e.g. GBM, lymphoma, metastases)
- drugs (amphetamine, cocaine, alcohol, anticoagulants, etc.)
- coagulopathy (iatrogenic, leukemia, TTP, aplastic anemia)
- CNS infections (fungal, granulomas, herpes simplex encephalitis)
- post trauma (immediate or delayed, frontal and temporal lobes most commonly injured via coup-contrecoup mechanism)
- eclampsia
- post operative (post-carotid endarterectomy cerebral reperfusion, craniotomy)
- idiopathic

Epidemiology
- 12-15 cases/100,000 population/yr

Risk Factors
- increasing age (mainly >55 yr)
- male gender
- HTN
- Black/Asian > Caucasian
- previous CVA of any type (23x risk)
- both acute and chronic heavy alcohol use; cocaine, amphetamines
- liver disease
- anticoagulants

Clinical Features
- TIA-like symptoms often precede ICH, can localize to site of impending hemorrhage
- gradual onset of symptoms over minutes-hours, usually during activity
- H/A, N/V, and decreased LOC are common
- specific symptoms/deficits depend on location of ICH

Investigations
- baseline severity score such as the ICH Score should be performed as part of the initial workup
- hyperdense blood on non-contrast CT
- CTA routine, if spot sign (contrast in the hematoma) demonstrated there is high likelihood of clot growth

Treatment
- medical
  - decrease MAP to pre-morbid level or by ~20% (target BP 140/90) in ED
  - check PT/INR, and correct coagulopathy
  - control raised ICP (see Intracranial Pressure Dynamics, NS4)
  - corticosteroids should NOT be used for elevated ICP in ICH
  - levetiracetam/phenytoin for seizure prophylaxis
  - follow electrolytes (SIADH common)
  - angiogram to rule out vascular lesion unless >45 yr, known HTN, and putamen/thalamic/posterior fossa ICH (yield ~0%)
- surgical
  - craniotomy with evacuation of clot, treatment of source of ICH (i.e. AVM, tumour, cavernoma), ventriculostomy to treat hydrocephalus
  - indications
    - symptoms of raised ICP or mass effect
    - rapid deterioration (especially if signs of brainstem compression)
    - favourable location (e.g. cerebellar, non-dominant hemisphere)
    - young patient (<50 yr)
    - if tumour, AVM, aneurysm, or cavernoma suspected (resection or clip to decrease risk of rebleed)
  - contraindications
    - small bleed: minimal symptoms, GCS >10
    - poor prognosis: massive hemorrhage (especially dominant lobe), low GCS/coma, lost brainstem function
    - medical reasons (e.g. very elderly, severe coagulopathy, difficult location [e.g. basal ganglia, thalamus])

ICH Score Components
- GCS score
- ICH volume
- Presence of intraventricular hemorrhage
- Infrafrontal origin
- Age

Early Surgery Versus Initial Conservative Treatment in Patients With Spontaneous Supratentorial Lobar Intracerebral Hematomas (STICH-II): A Randomized Trial
Lancet. 2013 Aug 3; 382(9890): 397-408
Summary: The STICH II (international, parallel-group trial comparing early surgical hematoma evacuation within 12 hour of randomization + medical treatment vs initial medical treatment alone) results confirm that early surgery does not increase the rate of death or disability at 6 months and might have a small but clinically relevant survival advantage for patients with spontaneous superficial intracerebral hemorrhage without intraventricular hemorrhage.

Location of ICH
- Basal Ganglia/Internal Capsule (50%)
- Thalamus (15%)
- Cerebral White Matter (15%)
- Cerebellum/Brainstem – usually pons (15%)
- Other (5%)

AVM grades calculated by adding the 3 individual Spetzler-Martin Scale scores from the above table. e.g. a 2 cm tumour in none eloquent location without deep venous drainage = Grade I
Vascular Malformations

Types
- arteriovenous malformations (AVMs)
- cavernous malformations (= cavernomas, cavernous hemangiomas/angiomas)
- venous angioma
- capillary telangiectasias
- arteriovenous fistula (AVF) (carotid-cavernous fistula, dural AVF, vein of Galen aneurysm)
- “angiographically occult vascular malformations” (any type, 10% of malformations)

Arteriovenous Malformations, Cavernous Malformations, and Dural Fistulas

Cerebrospinal Fluid Fistulas

**Etiology**
- cranial or spinal
- traumatic: after head trauma, iatrogenic (post-transsphenoidal surgery, post skull base surgery)
- nontraumatic: high pressure (hydrocephalus, tumour), normal pressure (bone erosion secondary to infection, congenital defect)

**Clinical Features**
- otorrhea or rhinorrhea (clear fluid)
- low pressure headaches (worse when sitting up)
- confirmatory testing for CSF: β transferrin test, quantitative glucose analysis of fluid, “ring sign”, “reservoir sign”

**Investigations**
- CT (detect pneumocephalus, fractures, skull base defects), water contrast CT cisternography

**Treatment**
- lower ICP (avoid straining, acetazolamide to reduce CSF production, modest fluid restriction)
- persistent leak: may require continuous lumbar drainage via percutaneous catheter
- surgical indications: traumatic leak lasting >2 wk, spontaneous leaks, delayed onset of leak after trauma or surgery, leaks complicated by meningitis

**Stereotactic Radiosurgery For Cavernous Malformations (CM)**

**Summary**
- Stereotactic radiosurgery is a safe intervention for CMs, with advantages of reducing rebleed risk in patients with repeated pretreatment hemorrhage. Treating 50% with single bleed in less than 2 months. However, the morbidity of repeated hemorrhage outweighs any radiosurgery-related morbidity and early active management of deep-seated CMs should be considered.

**Methods**
- Retrospective analysis of 113 patients with 79 brainstem and 39 thalamic/basal ganglia CMs treated with gamma knife surgery.

**Results**
1. Patients with multiple symptomatic hemorrhages before radiosurgery (n=41): rebleed rate decreased from 30.5% per lesion to 15% for the first 2 years after radiosurgery and 0% for the subsequent years. Pretreatment multiple bleeds led to permanent deficits in 72% of these patients.
2. Patients with ≤1 symptomatic bleed before radiosurgery (n=77): natural history is uncertain due to short period between presenting bleed and treatment (median 1 year). Rate of hemorrhage was 3.5% for the first 2 years and 1.2% subsequently. Pretreatment hemorrhages led to permanent deficits in 43% of these patients (significantly lower than multiple-bleeds group, p<0.001).
3. Permanent adverse radionecrosis effects were rare (0.7%) and minor in both groups.
4. Posttreatment hemorrhages led to persistent deficits in 7.3% of patients.

**RED FLAGS for Back Pain**

**Back Pain**

- **Bowel/Badder (retention or incontinence)**
- **Anesthesia (saddle)**
- **Fatigue**
- **Cauda Equina**

- **Urinary retention or incontinence, fecal incontinence or loss of anal sphincter tone, saddle anesthesia, uni/bi lateral, leg weakness/pain**
- **Malignancy**

- **Age ≥50 yr, previous Hx of cancer, pain unreleaved by bed rest, constitutional symptoms**
- **Infection**
  - Increased ESR, IV drug use, immunosuppressed, fever
- **Compression Fracture**
  - **Age >50 yr, trauma, prolonged steroid use**
**Root Compression**

- radiculopathy is a pain and/or sensorimotor deficit syndrome that involves compression of a nerve root. Nerve compression generally occurs as a result of disc herniation, degenerative disc diseases (spondylosis), instability and rarely, masses
- patients generally present with referred pain, sensory changes (numbness and/or tingling) or weakness. Whereas patients might sometime describe sensory changes in a dermatomal distribution, the referred pain will not be in a dermatomal distribution. The areas of pain and altered sensorium may be incongruent
- muscle innervation has less overlap than sensory innervation and hence is a better predictor of level of pathology

**Differential Diagnosis**
- herniated disc
- neoplasm (neurofibroma, schwannoma)
- synovial cyst, abscess
- hypertrophic bone/spur

**Cervical Disc Syndrome**

**Etiology**
- nucleus pulposus herniates through annulus fibrosus and impinges upon nerve root, most commonly at C6-C7 (C7 root)

**Clinical Features**
- pain in arm follows nerve root distribution, worse with neck extension, ipsilateral rotation, and lateral flexion (all compress the ipsilateral neural foramen)
- LMN signs and symptoms
- central cervical disc protrusion causes myelopathy as well as nerve root deficits

**Investigations**
- if red flags: C-spine x-ray, CT, MRI (imaging of choice)
- only consider EMG, nerve conduction studies if diagnosis uncertain and presenting more as peripheral nerve issue

**Treatment**
- **conservative**
  - no bedrest unless severe radicular symptoms
  - activity modification, patient education (reduce sitting, lifting)
  - physiotherapy, exercise programs focus on strengthening core muscles
  - analgesics, NSAIDs are more efficacious
  - avoid cervical manipulation, like traction
- **surgical indications**
  - anterior cervical discectomy is usual approach
  - intractable pain despite adequate conservative treatment for >3 mo
  - progressive neurological deficit

**Prognosis**
- 95% improve spontaneously in 4-8 wk

**Table 14. Lateral Cervical Disc Syndromes**

Cervical Spondylosis

Definition
- progressive degenerative process of cervical spine leading to canal stenosis – congenital spinal stenosis, degeneration of intervertebral discs, hypertrophy of lamina, dura, or ligaments, subluxation, altered mobility, telescoping of the spine due to loss of height of vertebral bodies, alteration of normal lordotic curvature
- resultant syndromes: mechanical neck pain, radiculopathy (root compression), myelopathy (spinal cord compression)

Epidemiology
- typically begins at age 40-50, M>F, most commonly at the C5-C6 > C6-C7 levels

Pathogenesis
- any of: disc degeneration/herniation, osteophyte formation, ossification, and hypertrophy of ligaments
- pathophysiology includes static compression, dynamic compression and vascular compromise

Clinical Features
- insidious onset of mechanical neck pain exacerbated by excess vertebral motion (particularly rotation and lateral bending with a vertical compressive force – Spurling’s test)
- the earliest symptoms are gait disturbance and lower extremity weakness or stiffness
- occipital H/A is common
- radiculopathy may involve 1 or more roots, and symptoms include neck, shoulder and arm pain, paresthesias and numbness
- cervical spondylotic myelopathy (CSM) may present with
  - weakness (upper > lower extremity), lower extremity weakness (corticospinal tracts) is most worrisome complaint
  - decreased dexterity, loss of fine motor control
  - sensory changes
  - UMN findings such as hyperreflexia, clonus, and Babinski reflex
  - funicular pain, characterized by burning and stinging ± Lhermitte’s sign (lightning-like sensation down the back with neck flexion)

Investigations
- x-ray of cervical spine ± flexion/extension (alignment, fractures)
- MRI most useful for determination of compression of the neural element
- CT is only used for better determination of bony anatomy (i.e. OPLL)
- EMG/nerve conduction studies reserved for peripheral nerve investigation

Treatment
- nonsurgical: prolonged immobilization with cervical bracing (limit movement to minimize cumulative trauma to spinal cord), bed rest, anti-inflammatory medications
- surgical: anterior approach (anterior cervical disectomy or corpectomy), posterior approach (decompressive cervical laminectomy)
- In multilevel CSM, an anterior approach is associated with better postoperative neural function but has a higher complication and reoperation rate than the posterior group
- surgical indications: myelopathy with motor impairment, progressive neurologic impairment, intractable pain
- complete remission almost never occurs. Surgical decompression may stop progression of disease

Lumbar Disc Syndrome

Etiology
- postero-laterally herniated disc compressed nerve root exiting BELOW the level of the disc or the traversing nerve root
- far lateral disc herniation compressed nerve root AT the level of the disc or the exiting nerve root
- central herniation causes cauda equina or lumbar stenosis (neurogenic claudication)

Clinical Features
- initial back pain, then leg pain > back pain
- limited back movement (especially forward flexion) due to pain
- motor weakness, dermatomal sensory changes, decreased reflexes
- exacerbation with valsalva; relief with flexing the knee or thigh
- nerve root tension signs
  - straight leg raise (SLR, Laségue’s test) or crossed SLR (pain should occur at less than 60º) suggests L5, S1 root involvement
  - femoral stretch test suggests L2, L3, or L4 root involvement

Efficacy and Safety of Surgical Decompression in Patients with Cervical Spondylotic Myelopathy: Results of the AOSpine North America Prospective Multi-centre Study

Purpose: Evaluate impact of surgical decompression on functional, CQL, and disability outcomes 1 yr post-surgery in patients with cervical spondylotic myelopathy.

Methods: 278 patients with mild to severe symptomatic cervical spondylotic myelopathy and MRI evidence of spinal cord compression were followed for 1 yr following surgical decompression. Outcomes (mJOA score, Nurick grade, Neck Disability Index, Short Form-36v2) were compared to preoperative values. Treatment-related complication data was collected.

Results: There was significant improvement (P<0.05) from baseline in mJOA score, Nurick grade, NDI score, and all SF-36v2 health dimensions other than general health. 18.7% of patients experienced complications with no significant differences among the severity groups.

Conclusion: Surgical decompression of cervical spondylotic myelopathy is associated with improved function, disability, and QOL outcomes at 1 yr.
Investigations
- MRI is modality of choice
- x-ray spine (only to rule out other lesions), CT (bony anatomy)
- myelogram and post-myelogram CT (only if MRI is contraindicated)

Treatment
- conservative (same as cervical disc disease)
- surgical indications: same as cervical disc + cauda equina syndrome

Prognosis
- 95% improve spontaneously within 4-8 wk
- those who do not improve with conservative treatment achieve symptom relief quicker with surgery than continuation of conservative management; however, the long-term outcome after surgery is comparable to conservative therapy
- do not follow patients with serial MRIs; clinical status is more important at guiding management

Cauda Equina Syndrome

Etiology
- compression or irritation of lumbosacral nerve roots below conus medullaris (below L2 level)
- decreased space in the vertebral canal below L2
- common causes: herniated disc ± spinal stenosis, vertebral fracture, and tumour

Clinical Features
- usually acute (develops in less than 24 h); rarely subacute or chronic
- motor (LMN signs)
  - weakness/paraparesis in multiple root distribution
  - reduced deep tendon reflexes (knee or ankle)
- autonomic
  - urinary retention (or overflow incontinence) and/or fecal incontinence due to loss of anal sphincter tone
- sensory
  - low back pain radiating to legs (sciatica) aggravated by Valsalva maneuver and by sitting; relieved by lying down
  - bilateral sensory loss or pain: depends on the level affected
  - saddle area (S2-S5) anesthesia
  - sexual dysfunction (late finding)

Investigations
- urgent MRI to confirm compression of S2-S3-S4 nerve root by a large disc herniation
- post-void residual very helpful to determine if true retention is present; volumes controversial but anything over 250 cc in a healthy individual is cause for concerns
Treatment
- surgical decompression (<48 h) to preserve bowel, bladder, and sexual function, and/or to prevent progression to paraplegia
- Consult radiation oncology for urgent symptomatic management if palliative oncology patient

Prognosis
- markedly improves with surgical decompression
- recovery correlates with function at initial presentation: if patient is ambulatory, likely to continue to be ambulatory; if unable to walk, unlikely to walk after surgery

Lumbar Spinal Stenosis

Etiology
- congenital narrowing of spinal canal combined with degenerative changes (herniated disc, hypertrophied facet joints, and ligamentum flavum)

Clinical Features
- gradually progressive back and leg pain with standing and walking that is relieved by sitting or lying down (neurogenic claudication – 60% sensitive)
- neurologic exam may be normal, including straight leg raise test

Investigations
- MRI is the optimal investigation to confirm and localize the level of stenosis (unlike nerve root compression which can be localized with clinical exam)

Treatment
- conservative: NSAIDs, analgesia
- surgical: laminectomy with root decompression (the role of fusion may need to be considered if the amount of bone removed with the laminectomy results in destabilization)

Neurogenic Claudication

Etiology
- ischemia of lumbosacral nerve roots secondary to vascular compromise and increased demand from exertion, often associated with lumbar stenosis

Clinical Features
- dermatomal pain/paresthesia/weakness of buttock, hip, thigh, or leg initiated by standing or walking
- slow relief with postural changes (sitting >30 min), NOT simply exertion cessation
- may be elicited with lumbar extension, but may not have any other neurological findings, no signs of vascular compromise (e.g. ulcers, poor capillary refill, etc.)

Investigations
- bicycle test may help distinguish neurogenic claudication (NC) from vascular claudication (the waist-flexed individuals on the bicycle with NC can last longer)

Treatment
- same as for lumbar spinal stenosis

Surgical vs. Non-Operative Treatment for Lumbar Spinal Stenosis Four-Year Results of the Spine Outcomes Research Trial (SPORT)

Spine 2010. 35(14): 1329-1338

Objective: To compare 4 year outcomes of surgery to non-operative care for spinal stenosis.
Methods: Surgical candidates from 13 centers in 11 U.S. states with at least 12 weeks of symptoms and confirmatory imaging were enrolled in a randomized cohort (RC) or observational cohort (OC). Treatment was standard decompressive laminectomy or standard non-operative care. Primary outcomes were SF-36 bodily pain (BP) and physical function (PF) scales and the modified Oswestry Disability index (ODI) assessed at 6 weeks, 3 months, 6 months and yearly up to 4 years.
Conclusions: Patients with symptomatic spinal stenosis treated surgically compared to those treated non-operatively maintain substantially greater improvement in pain and function through four years.

Key Features of Neurogenic vs. Vascular Claudication

Neurogenic Claudication: dermatomal distribution with positional relief occurring over minutes
Vascular Claudication: sclerotomal distribution with relief occurring with rest over seconds
Intradural Intramedullary Lesions

Syringomyelia (Syrinx)

Definition
- Cystic cavitation of the spinal cord
- Presentation is highly variable, usually progresses over months to years
- Initially pain, weakness; later atrophy and loss of pain and temperature sensation

Etiology
- 70% are associated with Chiari I malformation, 10% with basilar invagination
- Post-traumatic
- Tumour
- Tethered cord

Clinical Features
- Nonspecific features for any intramedullary spinal cord pathology
  - Initially pain, weakness, atrophy, then loss of pain and temperature (spinothalamic tract) in upper extremities (central syrinx) with progressive myelopathy over years
  - Sensory loss with preserved touch and proprioception (DCML) in a band-like distribution at the level of cervical syrinx
  - Dysesthetic pain often occurs in the distribution of the sensory loss
  - LMN arm/hand weakness or wasting
  - Painless neuropathic arthropathies (Charcot’s joints), especially in the shoulder and neck due to loss of pain and temperature sensation

Investigations
- MRI is best method, myelogram with delayed CT

Treatment
- Treat underlying cause (e.g., posterior fossa decompression for Chiari I, surgical removal of tumour if causing a syrinx)
- Rarely does the syrinx need to be shunted, only when progressive and size allows for insertion of tube

Spinal Cord Syndromes

Complete Spinal Cord Lesion
- Bilateral loss of motor/sensory and autonomic function at ≥4 segments below lesion/injury, with UMN signs
- About 3% of patients with complete injuries will develop some recovery within 24 h, beyond 24 h, no distal function will recover

Incomplete Spinal Cord Lesion
- Any residual function at ≥4 segments below lesion
- Signs include sensory/motor function in lower limbs and “sacral sparing” (perianal sensation, voluntary rectal sphincter contraction)

Table 17. Comparison Between Incomplete Spinal Cord Lesion Syndromes

</tr>
<tr>
<td>Neurotmesis (class III)</td>
<td>Nerve completely transected</td>
<td>Need surgical repair for possibility of recovery</td>
</tr>
</tbody>
</table>

Etiology

• ischemia
• nerve entrapment – nerve compressed by nearby anatomic structures, often secondary to localized, repetitive mechanical trauma with additional vascular injury to nerve

Investigations

• clinical exam: power, sensation, reflexes, localization via Tinel's sign (paresthesias elicited by tapping along the course of a nerve)
• electrophysiological studies: EMG, nerve conduction study (assess nerve integrity and monitoring recovery after 2-3 wk post-injury)
• labs: blood work (e.g. CBC, TSH, Vitamin B12), CSF
• imaging: C-spine, chest/bone x-rays, myelogram, CT, magnetic resonance neurography, angiogram if vascular damage is suspected

Treatment

• early neurosurgical consultation if injury is suspected

Table 19. Treatment by Injury Type

</tr>
</tbody>
</table>

Complications

• neuropathic pain: with neuroma formation
• complex regional pain syndrome: with sympathetic nervous system involvement

SPECIALTY TOPICS

Neurotrauma

Trauma Management (see Emergency Medicine, ER7)

Indications for Intubation in Trauma

1. depressed LOC (patient cannot protect airway); usually GCS ≤8
2. need for hyperventilation
3. severe maxillofacial trauma: patency of airway is doubtful
4. need for pharmacologic paralysis for evaluation or management

• if basal skull fracture suspected, avoid nasotracheal intubation as may inadvertently enter brain
• note: intubation prevents patient’s ability to verbalize for determining GCS

Glasgow Coma Scale

<table>
<thead>
<tr>

Best response for each component recorded individually: (e.g. E4V3M2) w/13 is mild injury; 9-12 is moderate injury; ≤8 is severe injury
Trauma Assessment

Initial Management

ABCs of Trauma Management
- see Emergency Medicine, ER2

NEUROLOGICAL ASSESSMENT

Mini-History
- period of LOC, post-traumatic amnesia, loss of bowel/bladder control, loss of sensation, weakness, type of injury/accident

Neurological Exam
- GCS
- head and neck (lacerations, bruises, basal skull fracture signs, facial fractures, foreign bodies)
- spine (palpable deformity, midline pain/tenderness)
- eyes (pupillary size and reactivity)
- brainstem (breathing pattern, CN palsies)
- cranial nerve exam
- motor exam, sensory exam (only if GCS is 15), reflexes
- sphincter tone, saddle sensation
- record and repeat neurological exam at regular intervals

Investigations
- spinal injury precautions (cervical collar) are continued until C-spine is cleared
- C,T,L-spine x-rays
  - AP, lateral, odontoid views for C-spine (must see from C1 to T1; swimmer's view if necessary) or CT
  - rarely done: oblique views looking for pars interarticularis fracture (“Scottie dog” sign)
- CT head and upper C-spine (whole C-spine if patient unconscious) look for fractures, loss of mastoid or sinus air spaces, blood in cisterns, pneumocephalus
- cross and type, ABG, CBC, drug screen (especially alcohol)
- chest and pelvic x-ray as indicated

TREATMENT

Treatment for Minor Head Injury (GCS 13-15)
- observation over 24-48 h
- wake every hour
- judicious use of sedatives or pain killers during monitoring period
- outpatient: advise patients to undergo stepwise approach to return to play and return to school (include references for these new recommendations)

Treatment for Severe Head Injury (GCS ≤8)
- clear airway and ensure breathing (if GCS ≤8, intubate)
- secure C-spine
- maintain adequate BP
- monitor for clinical deterioration
- monitor and manage increased ICP if present (see Herniation Syndromes, NS7)

Admission required if:
- skull fracture (indirect signs of basal skull fracture, see Head Injury, NS32)
- confusion, impaired consciousness, concussion with >5 min amnesia
- focal neurological signs, extreme H/A, vomiting, seizures
- unstable spine
- use of alcohol
- poor social support
Head Injury

Epidemiology
- M:F = 2-3:1

Pathogenesis
- acceleration/deceleration: contusions, subdural hematoma, axon and vessel shearing/mesencephalic hematoma
- impact: skull fracture, concussion, epidural hematoma
- penetrating: worse with high velocity and/or high missile mass
  - low velocity: highest damage to structures on entry/exit path
  - high velocity: highest damage away from missile tract

Scalp Injury
- rich blood supply
- considerable blood loss (vessels contract poorly when ruptured)
- minimal risk of infection due to rich vascularity

Skull Fractures
- depressed fractures: double density on skull x-ray (outer table of depressed segment below inner table of skull), CT with bone window is gold standard
- simple fractures (closed injury): no need for antibiotics, no surgery
- compound fractures (open injury): increased risk of infection, surgical debridement within 24 h is necessary
  - internal fractures into sinus may lead to meningitis, pneumocephalus
  - risk of operative bleed may limit treatment to antibiotics
- basal skull fractures: not readily seen on x-ray, rely on clinical signs
  - retroauricular ecchymoses (Battle’s sign)
  - periorbital ecchymoses (raccoon eyes)
  - hemotympanum
  - CSF rhinorrhea, otorrhea (suspect CSF if halo or target sign present); suspect with Lefort II/III midface fracture

Cranial Nerve Injury
- most traumatic causes of cranial nerve injury do not warrant surgical intervention
- surgical intervention
  - CN II: local eye/orbit injury
  - CN III, IV, VI: if herniation secondary to mass
  - CN VIII: repair of ossicles
- CN injuries that improve
  - CN I: recovery may occur in a few months; most do not improve
  - CN III, IV, VI: majority recover
  - CN VII: recovery with delayed lesions
  - CN VIII: vestibular symptoms improve over weeks, deafness usually permanent (except when resulting from hemotympanum)

Arterial Injury
- e.g. carotid-cavernous (C-C) fistula, carotid/vertebral artery dissection

Intracranial Bleeding
- see Blood, NS16 and Cerebrovascular Disease, NS18

Brain Injury

Primary Impact Injury
- mechanism of injury determines pathology: penetrating injuries, direct impact
  - low velocity: local damage
  - high velocity: distant damage possible (due to wave of compression), concussion
- concussion: a trauma-induced alteration in mental status
  - American Academy of Neurology (AAN) Classification
  - no parenchymal abnormalities on CT
- coup (damage at site of blow) and contrecoup (damage at opposite site of blow) (Figure 27)
  - acute decompression causes cavitation followed by a wave of acute compression
- contusion (hemorrhagic)
  - high density areas on CT ± mass effect
  - commonly occurs with brain impact on bony prominences (inferior frontal lobe, pole of temporal lobe)
- diffuse axonal injury/shearing
  - wide variety of damage results
  - may tear blood vessels (hemorrhagic foci)
  - often the cause of decreased LOC if no space-occupying lesion on CT

The Canadian CT Head Rule for Patients with Minor Head Injury
Lancet 2001;357:1391-1396
CT Head is only required for patients with minor head injuries with any one of the following
High Risk (for neurological intervention)
- GCS score <15 at 2 h after injury.
- Suspected open or depressed skull fracture.
- Any sign of basal skull fracture (hemotympanum, “raccoon” eyes, cerebrospinal fluid otorrhea/ rhinorrhea, Battle’s sign)
- Vomiting ≥2 episodes
- Age ≥65 yr.

Medium Risk (for brain injury on CT)
- Amnesia after impact >30 min.
- Dangerous mechanism (pedestrian struck by motor vehicle, occupant ejected from motor vehicle, fall from height >3 feet or five stairs).

Minor Head Injury is defined as witnessed loss of consciousness, definite amnesia, or witnessed disorientation in a patient with a GCS score of 13-15.

Figure 27. CT showing coup-contrecoup injury

AAN Classification
Grade 1: altered mental status <15 min
Grade 2: altered mental status >15 min
Grade 3: any loss of consciousness

SIADH → hyponatremia
DI → hypernatremia
Secondary Pathologic Processes
• same subsequent biochemical pathways for each traumatic etiology
• delayed and progressive injury to the brain due to
  • high glutamate release → NMDA receptor activation → cytotoxic cascade
  • cerebral edema
  • intracranial hemorrhages
  • ischemia/infarction
  • raised ICP, intracranial HTN
  • hydrocephalus

Extracranial Conditions
• hypoxemia
  • due to trauma to the chest, upper airway, brainstem
  • extremely damaging to vulnerable brain cells
  • leads to ischemia, raised ICP
• hypovolemia
  • leads to raised ICP (secondary to vasodilation)
  • systemic hypotension
  • caused by blood loss (e.g. ruptured spleen)
  • loss of cerebral autoregulation leads to decreased CPP ischemia
• hypothermia
  • leads to increased brain metabolic demands → ischemia
  • fluid and electrolyte imbalance
  • iatrogenic (most common)
  • SIADH caused by head injury
  • diabetes insipidus (DI)
  • may lead to cerebral edema and raised ICP
  • coagulopathy

Intracranial Conditions
• raised ICP due to traumatic cerebral edema OR traumatic intracranial hemorrhage

Brain Injury Outcomes
• mildly traumatic (GCS 13-15): post-concussive symptoms: H/A, fatigue, dizziness
• nausea, blurred vision, diplopia, memory impairment, tinnitus, irritability, low concentration; 50% at 6 wk, 14% at 1 yr
• moderately traumatic (GCS 9-12): proportional to age (>40) and CT findings; 60% good recovery 26% moderately disabled, 7% severely disabled 7% vegetative/dead
• severe (GCS ≤8): difficult to predict, correlates with post-resuscitation GCS (especially motor) and age

Late Complications of Head/Brain Injury
• seizures: 5% of head injury patients develop seizures
  • incidence related to severity and location of injury (increased with local brain damage or intracranial hemorrhage)
  • post-traumatic seizure may be immediate, early, or late
  • presence of early (within first wk) post-traumatic seizure raises incidence of late seizures
• meningitis: associated with CSF leak from nose or ear
• hydrocephalus: acute hydrocephalus or delayed normal pressure hydrocephalus (NPH)
• Post-Concussion Syndrome (PCS)/neuro-psychiatric effects

Spinal Cord Injury
• see Orthopedics, OR22 and Emergency Medicine, ER9

NEUROGENIC AND SPINAL SHOCK
1. neurogenic shock: hypotension that follows SCI (sBP usually ≤80 mmHg) caused by
  • interruption of sympathetics (unopposed parasympathetics) below the level of injury
  • loss of muscle tone due to skeletal muscle paralyis below level of injury → venous pooling (relative hypovolemia)
  • blood loss from associated wounds (true hypovolemia)
2. spinal shock: transient loss of all neurologic function below the level of the spinal cord injury, causing flacid paralysis and areflexia for variable periods

Whiplash-Associated Disorders
• definition: traumatic injury to the soft tissue structures in the region of the cervical spine due to hyperflexion, hyperextension, or rotational injury to the neck
Initial Management of SCI
- major causes of death in SCI are aspiration and shock
- the following patients should be treated as having a SCI until proven otherwise:
  - all victims of significant trauma
  - minor trauma patients with decreased LOC or compla nts of neck or back pain, weakness, abdominal breathing, numbness/tingling, or priapism

Stabilization and Initial Evaluation in the Hospital
1. ABCs, immobilization (backboard/head strap), oxygenation, Foley catheter to urometer, temperature regulation
2. hypotension: maintain SBP >90 mmHg with pressors (dopamine), hydration, and atropine
   ■ DVT prophylaxis
3. monitor CBC/electrolytes
4. focused history (see Trauma Assessment, NS29)
5. spine palpation: point tenderness or deformity
6. motor level assessment (including rectal exam for voluntary anal sphincter contraction)
7. sensory level assessment: pinprick, light touch, and proprioception
8. evaluation of reflexes
9. signs of autonomic dysfunction: altered level of perspiration, bowel or bladder incontinence, priapism
10. radiographic evaluation
    ■ 3 views C-spine x-rays (AP, lateral, and odontoid) to adequately visualize C1 to C7-T1 junction
    ■ flexion-extension views to disclose occult instability
    ■ CT scan (bony injuries) typically most trauma centres use CT as the modality of choice for looking at fractures, very sensitive with the high resolution scanners
    ■ MRI mandatory if neurological deficits (soft tissue injuries)

Medical Management Specific to SCI
- option: methylprednisolone (given within 8 h of injury) this is controversial and you need to confer with Neurosurgery service
- ± decompression in acute non penetrating SCI

Fractures of the Spine

FRACTURES AND FRACTURE-DISLOCATIONS OF THE THORACIC AND LUMBAR SPINE
- assess ligamentous instability using flexion/extension x-ray views of ± MRI
- thoracolumbar spine unstable if 4/6 segments disrupted (3 columns divided into left and right)
  ■ anterior column: anterior half of vertebral body, disc, and anterior longitudinal ligament
  ■ middle column: posterior half of vertebral body, disc, and posterior longitudinal ligament
  ■ posterior column: posterior arch, facet joints, pedicle, lamina and supraspinous, interspous, and ligamentum ligaments

Types of Injury

Table 20. Denis Classification of Spinal Trauma

<table>
<thead>
<tr>
<th>Fracture Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compression Fracture (58%)</td>
<td>Produced by flexion Posterior ligamentum complex (supraspinous and interspinous ligaments, ligamentum flavum, and intervertebral joint capsules) remain intact Fractures are stable but lead to kyphotic deformity</td>
</tr>
<tr>
<td>Burst Fracture (17%)</td>
<td>Stable: anterior and middle columns parted with bone retropulsed nearby Hallmark is pedicle widening on AP x-ray Spinal cord (seen on x-ray and CT) posterior column is uninjured Unstable: same as the stable but with posterior column disruption (usually ligamentous)</td>
</tr>
<tr>
<td>Flexion Distraction Injury (6%)</td>
<td>Hyperflexion and distraction of posterior elements Middle and posterior columns fail in distraction Classic: Chance = horizontal fracture through posterior arch, pedicles, posterior vertebral body Can be purely ligamentous, i.e. through PLL and disc</td>
</tr>
<tr>
<td>Fracture-Dislocation (6%)</td>
<td>Anterior and cranial dislocation of superior vertebral body → 3 column failure Three types: (1) flexion-rotation, (2) flexion-distraction, (3) shear/hyperextension (rare)</td>
</tr>
</tbody>
</table>

Management of Thoracolumbar Injury
- severity and management based on TLICS classification
FRACTURES OF THE CERVICAL SPINE

Types of Injury

Table 21. Fracture Patterns of the Cervical Spine

<table>
<thead>
<tr>
<th>Fracture Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>C1 Vertebral Fracture (Jefferson fracture)</td>
<td>Vertical compression forces the occipital condyles of the skull down on the C1 vertebra (atlas) pushing the lateral masses of the atlas outward and disrupting the ring of the atlas Also can cause an occipital condylar fracture</td>
</tr>
<tr>
<td>Odontoid Fracture</td>
<td>Causes C1 and odontoid of C2 to move independently of C2 body This occurs because Normally C1 vertebra and odontoid of C2 are a single functional unit Alar and transverse ligaments on posterior aspect of odontoid usually remain intact after injury Patients often report a feeling of instability and present holding their head with their hands Type II fracture the most common</td>
</tr>
<tr>
<td>C2 Vertebral Fracture (hangman fracture)</td>
<td>Bilateral fracture through the pars interarticularis of C2 with subluxation of C2 on C3 (spondylolisthesis of axis) Usually neurologically intact</td>
</tr>
<tr>
<td>Clay-Shoveler Fracture</td>
<td>Avulsion of spinous process, usually C6 or C7</td>
</tr>
</tbody>
</table>

Imaging

- AP spine x-ray (open-mouth and lateral view), CT

Treatment

- immobilization in cervical collar or halo vest until healing occurs (usually 2-3 mo)
- Type II and III odontoid fractures
- consider surgical fixation for comminution, displacement, or inability to maintain alignment with external immobilization
- confirm stability after recovery with flexion-extension x-rays

Neurologically Determined Death

Definition

- irreversible and diffuse brain injury resulting in absence of clinical brain function
- cardiovascula activity may persist for up to 2 wk

Criteria of Diagnosis

- prerequisites: no CNS depressant drugs/neuromuscular blocking agents, no drug intoxication/ poisoning, temperature >32ºC, no electrolyte/acid-base/endocrine disturbance
- absent brainstem reflexes: pupillary light reflex, corneal reflexes, oculocephalic response, caloric responses (e.g. no deviation of eyes to irrigation of each ear with 50 cc of ice water – allow 1 min after injection, 5 min between sides), pharyngeal and tracheal reflexes, cough with tracheal suctioning, absent respiratory drive at PaCO2 >60 mmHg or >20 mmHg above baseline (apnea test)
- 2 evaluations separated by time, usually performed by two specialists (e.g. anesthetist, neurologist, neurosurgeon)
- confirmatory testing: flat EEG, absent perfusion assessed with cerebral angiogram

Coma

Definition

- an unrousable state in which patients show no meaningful response to environmental stimuli

Pathophysiology

- lesions affecting the cerebral cortex bilaterally, the reticular activating system (RAS) or their connecting fibres
- focal supratentorial lesions do not alter consciousness except by herniation (compression on the brainstem or on the contralateral hemisphere) or by precipitating seizures

Classification

- structural lesions (tumour, pus, blood, infarction, CSF): 1/3 of comas
  - supratentorial mass lesion: leads to herniation
  - infratentorial lesion: compression of or direct damage to the RAS or its projections
- metabolic disorders/diffuse hemispheric damage: 2/3 of comas
  - deficiency of essential substrates (e.g. oxygen, glucose, vitamin B12)
  - exogenous toxins (e.g. drugs, heavy metals, solvents)
  - endogenous toxins/systemic metabolic diseases (e.g. uremia, hepatic encephalopathy, electrolyte imbalances, thyroid storm)
- infections (meningitis, encephalitis)
- trauma (concussion, diffuse axonal damage)
Investigations and Management
- **ABCs**
- labs: electrolytes, extended electrolytes, TSH, LFTs, Cr, BUN, toxin screen, glucose
- CT/MRI, LP, EEG

**Persistent Vegetative State**

**Definition**
- a condition of complete unawareness of the self and the environment accompanied by sleep-wake cycles with either complete or partial preservation of hypothalamic and brainstem autonomic function
- "awake but not aware"
- follows comatose state

**Etiology/Prognosis**
- most commonly caused by cardiac arrest or head injury
- due to irreversible loss of cerebral cortical function but intact brainstem function
- average life expectancy is 2-5 yr

---

**Pediatric Neurosurgery**

**Spinal Dysraphism**

- spinal dysraphism refers to a spectrum of congenital anomalies resulting in a defective neural arch through which CNS elements are herniated
- the spectrum is divided largely into aperta (visible lesion; no skin covering) and occulta (no visible lesion; skin covering)

**Table 22. Summary of Spinal Dysraphic Anomalies**

<table>

Intraventricular Hemorrhage

- see Pediatrics, P63

Hydrocephalus in Pediatrics

Etiology
- congenital
  - aqueductal anomalies, primary aqueductal stenosis in infancy
  - secondary gliosis due to intrauterine viral infections (mumps, varicella, TORCH)
  - Dandy-Walker malformation (2-4%)
  - Chiari malformation, especially Type II
  - myelomeningocele
- acquired
  - post meningitis
  - post hemorrhage (SAH, IVH)
  - masses (vascular malformation, neoplastic)

Clinical Features
- symptoms and signs of hydrocephalus are age related in pediatrics
- increased head circumference (HC), bulging anterior fontanelle, widened cranial sutures
- irritability, lethargy, poor feeding, and vomiting
- "cracked pot" sound on cranial percussion
- scalp vein dilation (increased collateral venous drainage)
- sunset sign – forced downward deviation of eyes
- episodic bradycardia and apnea

Investigations
- skull x-ray, U/S, CT, MRI, ICP monitoring

Treatment
- similar to adults (see Hydrocephalus Treatment, NS9)

Dandy-Walker Malformation

Definition
- atresia of foramina of Magendie and Luschka, resulting in:
  - complete or incomplete agenesis of the cerebellar vermis with widely separated, hypoplastic cerebellar hemispheres
  - can be detected in utero
  - posterior fossa cyst, enlarged posterior fossa
  - dilatation of 4th ventricle (also 3rd and lateral ventricles)
- associated anomalies
  - hydrocephalus (90%)
  - agenesis of corpus callosum (17%)
  - occipital encephalocele (7%)

Epidemiology
- 2-4% of pediatric hydrocephalus

Clinical Features
- 20% are asymptomatic, seizures occur in 15%
- symptoms and signs of hydrocephalus combined with a prominent occiput in infancy
- ataxia, spasticity, poor fine motor control common in childhood

Investigations
- ultrasound, CT, MRI

Treatment
- asymptomatic patients require no treatment
- associated hydrocephalus requires surgical treatment
  - e.g. ventriculoperitoneal (VP) shunt, cystoperitoneal (CP) shunt, lumboperitoneal (LP) shunt,
    ventriculoatrial (VA) shunt, lumbar drain

Prognosis
- 75-100% survival, 50% have normal IQ
Chiari Malformations

Definition
• malformations at the medullary-spinal junction

Etiology
• unclear, likely maldevelopment/dysgenesis during fetal life

Categories

Table 23. Categories of Chiari Malformations

<table>
<thead>
<tr>
<th>Category</th>
<th>Type I</th>
<th>Type II</th>
</tr>
</thead>
<tbody>
<tr>
<td>Definition</td>
<td>Cerebellar tonsils lie below the level of the foramen magnum</td>
<td>Part of cerebellar vermis, medulla, and 4th ventricle extend through the foramen magnum often to midcervical region</td>
</tr>
<tr>
<td>Epidemiology</td>

</tr>
<tr>
<td></td>
<td>Syringomyelia (60%), Hydrocephalus (10%)</td>
<td></td>
</tr>
<tr>
<td>Investigations</td>
<td>MRI</td>
<td>MRI</td>
</tr>
<tr>
<td>Treatment</td>
<td>Symptomatic patients (early surgery recommended; &lt;2 yr post symptom onset) → suboccipital craniectomy, duraplasty</td>
<td>Preserved When symptomatic, check the shunt first. Then consider surgical decompression (which does not reverse intrinsic brainstem abnormalities) → cervical laminectomy, duraplasty</td>
</tr>
</tbody>
</table>

Craniosynostosis

Definition
• premature closure of the cranial suture(s)

Classification
• sagittal (most common): long narrow head with ridging sagittal suture (scaphocephaly)
• coronal: expansion in superior and lateral direction (brachiocephaly)
• metopic (trigonocephaly)
• lambdoid: least common

Epidemiology
• 0.6/1,000 live births, most cases are sporadic; familial incidence is 2% of sagittal and 8% of coronal synostosis

Clinical Features
• skull deformity raised ICP ± hydrocephalus
• ophthalmologic problems due to increased ICP or bony abnormalities of the orbit
• must differentiate between positional plagiocephaly (secondary to back sleeping)

Investigations
• plain radiographs, CT scan

Treatment
• parental counselling about nature of deformity, associated neurological symptoms
• surgery for cosmetic purposes, except in cases of elevated ICP (≥2 sutures involved)
Pediatric Brain Tumours

- see Tumours, NS11

Epidemiology
- 20% of all pediatric cancers (second only to leukemia)
- 60% of pediatric brain tumours are infratentorial
- pediatric brain tumours arise from various cellular lineages
  - glia: low-grade astrocytoma (supra- or infratentorial), anaplastic astrocytoma, glioblastoma multiforme (largely supratentorial) (see Astrocytoma, NS12)
  - primitive nerve cells: supratentorial PNET
  - 90% of neonatal brain tumours, infratentorial (medulloblastoma), pineal gland (pineoblastoma)
  - neuronal cells: germ cell tumour, craniopharyngioma, dermoid, meningioma, neurinoma (schwanoma), pituitary adenoma, others

Clinical Features
- vomiting, seizure, macrocrania, hydrocephalus
- developmental delay, poor feeding, failure to thrive
- often initially escapes diagnosis due to expansile cranium and neural plasticity in children

</table>
Surgical Management of Epilepsy

- see Neurology, N19 for the medical treatment of epilepsy

Indications
- medically refractory seizures, usually defined as seizures resistant to two first line anti-seizure medications used in succession
- identification of a distinct epileptogenic region through clinical history, EEG, MRI, and neuropsychological testing; other localizing investigations include magnetoencephalography, SPECT, and PET
- if a distinct epileptogenic region cannot be identified, the patient may be a candidate for a palliative procedure such as corpus callosotomy

Procedure
- adults: resection of the hippocampus and parahippocampal gyrus for mesial temporal lobe epilepsy arising from mesial temporal sclerosis
- children: resection of an epileptogenic space-occupying lesion
- hemispherectomy and corpus callosotomy are less common

Outcomes
- 41-79% of adult patients are seizure free for 5 yr after temporal lobe resection
- 58-78% of children are seizure free after surgery
- surgery is associated with improvements in preexisting psychiatric conditions such as depression and anxiety, as well as improvement in quality of life measures

Morbidity
- 0.4-4% of surgical patients will have partial hemianopsia, aphasia, motor deficit, sensory deficit, or cranial nerve palsy following anteromedial temporal lobectomies
- most patients will have some decline in verbal memory following dominant temporal lobectomy and in visuospatial memory in non-dominant temporal resection
- the degree of memory decline stabilizes after 1-2 yr

Predictors
- positive predictive factors for seizure freedom following anteromedial temporal lobectomy
  - hippocampal sclerosis (unilateral)
  - focal localization of interictal epileptiform discharges
  - absence of pre-operative generalized seizures
  - tumoural cause
  - complete resection of the lesion

Surgical Management for Trigeminal Neuralgia

- reserved for cases refractory to medical management; see Neurology, N42 for medical management

Surgical Options
- trigeminal nerve branch procedures
  - local blocks (phenol, alcohol)
  - neurectomy of the trigeminal branch
  - nerve branches
  - V1 block at the supraorbital, supratrochlear nerves
  - V2 block at the foramen rotundum or infraorbital nerves
  - V3 block at the foramen ovale
- percutaneous trigeminal rhizotomy
  - glycerol injection
  - mechanotrauma via catheter balloon
  - radiofrequency thermocoagulation
  - Gamma Knife® radiosurgery
  - microvascular decompression
  - posterior fossa craniotomy with microsurgical exploration of the root entry zone, displacement of the vessel impinging on the nerve with placement of non-absorbable Teflon® felt

Basic Anatomy Review

Placenta
- site of fetal nutritive, respiratory, and excretory function
- discoid mass composed of fetal (chorion frondosum) and maternal (decidua basalis) tissues divided by fissures into cotyledons (lobules) on the uterine side
- produces hormones such as progesterone, placental lactogen, estrogen, relaxin, β-hCG, and IGFs
- poor implantation can lead to spontaneous abortion
- abnormal location, implantation, or detachment can lead to antepartum hemorrhage (see Obstetrical Hemorrhage, OB13)

Pregnancy

Diagnosis of Pregnancy

History
- symptoms: amenorrhea, nausea and/or vomiting, breast tenderness, urinary frequency, and fatigue
- obstetrical and gynecological history
- obtain the year, location, mode of delivery, duration of labour, sex, gestational age, birth weight, and complications of every pregnancy; organize into GTPAL format
  - Gravidity (G)
    - G: total number of pregnancies of any gestation (multiple gestation=one pregnancy)
    - includes current pregnancy, abortions, ectopic pregnancies, and hydatidiform moles
Maternal Physiologic Adaptations to Pregnancy

Table 1. Physiologic Changes During Pregnancy

| Skin | Increased pigmentation of perineum and areola, chloasma (pigmentation changes under eyes and on bridge of nose), linea nigra (midline abdominal pigmentation), spider angiomas, palmar erythema due to increased estrogen, striae gravidarum due to connective tissue changes |
| Cardiovascular | Hyper-dynamic circulation  
| | Increased CO, H, and blood volume  
| | Decreased blood pressure: decreased PVR and decreased venous return from enlarging uterus compressing IVC and pelvic veins  
| | Increased venous pressure leads to risk of varicose veins, hemorrhoids, leg edema |
| Hematologic | Hemodilution causes physiologic anemia and apparent decrease in hemoglobin and hematocrit  
| | β-hCG: peptide hormone composed of α and β subunits produced by placental trophoblastic cells – maintains the corpus luteum during pregnancy  
| | • positive in serum 9 d post-conception, positive in urine 28 d after first day of LMP  
| | • plasma levels usually double every 1.4-2.0 d, peak at 8-10 wk, then fall to a plateau until delivery levels less than expected suggest: ectopic pregnancy, abortion, inaccurate dates, and some normal pregnancies  
| | • levels greater than expected suggest: multiple gestation, molar pregnancy, Trisomy 21, or inaccurate dates |
| Respiratory | Increased incidence of nasal congestion  
| | Hyperdynamic circulation  
| | Increased D: consumption to meet increased metabolic requirements  
| | Elevated diaphragm (i.e. patient appears more "barrel-chested")  
| | Increased minute ventilation leads to decreased CO2 resulting in mild respiratory alkalosis that helps CO2 diffuse across the placenta from fetal to maternal circulation  
| | Decreased TLC, FRC, and RV  
| | No change in VC and FEV: |
| Gastrointestinal | GERD due to increased intra-abdominal pressure and progesterone (causing decreased sphincter tone and delayed gastric emptying)  
| | Increased gallstones due to progesterone causing increased gallbladder stasis  
| | Constipation due to progesterone causing decreased GI motility and hemorrhoids as a result of constipation and increased intra-abdominal pressure |
| Genitourinary | Increased urinary frequency due to increased total urinary output  
| | Increased incidence of UTI and pyelonephritis due to urinary stasis (see Urinary Tract Infection, OB28)  
| | Glycosuria that can be physiologic especially in the 3rd trimester, consider testing for GDM if noted in first 2 trimesters  
| | Ureters and renal pelvis dilation (P>L): due to progesterone-induced smooth muscle relaxation and uterine enlargement  
| | Increased CO and thus increased GFR leads to decreased creatinine (normal in pregnancy 35-44 mmol/L), uric acid, and BUN |
| Neurologic | Increased incidence of carpal tunnel syndrome and Bell’s palsy |
| Endocrine | Thyroid: moderate enlargement (not clinically detectable) and increased basal metabolic rate  
| | Increased total thyroxine and thyroxine binding globulin (TBG)  
| | Free thyroxine index and TSH levels are normal  
| | Adrenal: maternal cortisol rises throughout pregnancy (total and free)  
| | Calcium: decreased total maternal Ca2+ due to decreased albumin  
| | Free ionized Ca2+ (i.e. active) proportion remains the same due to parathyroid hormone (PTH), results in increased bone resorption and gut absorption, increased bone turnover (but no loss of bone density due to estrogen inhibition) |

Parity (TPAL)  
- T: number of term infants delivered (>37 wk)  
- P: number of premature infants delivered (20-36+6 wk)  
- A: number of abortions (loss of intrauterine pregnancy prior to viability of fetus <20 wk and/or <500 g fetal weight)  
  - induced (therapeutic) and spontaneous (miscarriage)  
- L: number of living children

Physical Signs  
- Goodell's sign: softening of the cervix (4-6 wk)  
- Chadwick's sign: bluish discoloration of the cervix and vagina due to pelvic vasculature engorgement (6 wk)  
- Hegar's sign: softening of the cervical isthmus (6-8 wk)  
- uterine enlargement  
- breast engorgement, areola darkening, and prominent vascular patterns

Investigations  
- β-hCG: peptide hormone composed of α and β subunits produced by placental trophoblastic cells – maintains the corpus luteum during pregnancy  
  - positive in serum 9 d post-conception, positive in urine 28 d after first day of LMP  
  - plasma levels usually double every 1.4-2.0 d, peak at 8-10 wk, then fall to a plateau until delivery  
  - levels less than expected suggest: ectopic pregnancy, abortion, inaccurate dates, and some normal pregnancies  
  - levels greater than expected suggest: multiple gestation, molar pregnancy, Trisomy 21, or inaccurate dates  
- U/S:  
  - transabdominal  
  - 5 wk amenorrhea: gestational sac visible  
  - 6 wk: fetal pole visible  
  - 7-8 wk: fetal heart activity visible  
  - transvaginal  
  - 6-8 wk: intrauterine pregnancy visible
Antepartum Care

• can be provided by obstetrician, family physician, midwife, or multidisciplinary team (based on patient preference and risk factors)

Preconception Counselling

• 3-8 wk GA is a critical period of organogenesis, so early preparation is vital
• past medical history: optimize illnesses and medications prior to pregnancy (see Medical Complications of Pregnancy, OB25, and Medications, OB10)
• supplementation
  • folic acid: encourage diet rich in folic acid and supplementation 8-12 wks pre-conception until end of T1 to prevent NTDs
    • 0.4-1 mg daily in all women; 5 mg if previous NTD, antiepileptic medications, DM, or BMI >35 kg/m²
  • iron supplementation, prenatal vitamins
• risk modification
  • lifestyle: balanced nutrition and physical fitness
  • medications: discuss teratogenicity of medications so they may be adjusted or stopped if necessary
  • infection screening: rubella, HBsAg, VDRL, Pap smear, gonorrhea/chlamydia, HIV, TB testing based on travel and health care worker, history of varicella or vaccination, parvovirus immunity if exposed to small children, cytomegalovirus immunity if health care worker, toxoplasmosis serology if cats or gardening, last pertussis vaccine
  • genetic testing as appropriate for high risk groups (see Prenatal Screening, Table 2); consider genetics referral in known carriers, recurrent pregnancy loss/stillbirth, family members with developmental delay, birth anomalies, genetic diseases, consanguinity
  • social: smoking, alcohol, drug use, domestic violence (see Family Medicine, FM11, FM12, FM26)

Initial Prenatal Visit

• usually within 8-12 wk of the first day of LMP or earlier if <20 or >35 yr old, bleeding, very nauseous, or other risk factors present

History

• gestational age by dates from the first day of the LMP
  • Naegle’s rule: 1st day of LMP + 1 y + 7 days – 3 months
  • e.g. LMP = 1 Apr 2014, EDC = 8 Jan 2015 (modify if cycle >28 d by adding number of d >28)
  • if LMP unreliable, get a dating ultrasound which could coincide with nuchal translucency at ~12 wk
  • dates should change if T1 U/S is greater than 5 days in difference from LMP due date
  • history of present pregnancy (e.g. bleeding, N/V) and all previous pregnancies
  • past medical, surgical, and gynecological history
  • prescription and non-prescription medications
  • family history: genetic diseases, birth defects, multiple gestation, consanguinity
  • social history: smoking, alcohol, drug use, domestic violence (see Family Medicine, FM11, FM12, FM26)

Physical Exam

• complete physical exam to obtain baseline patient information  BP and weight important for interpreting subsequent changes

Investigations

• blood work
  • CBC, blood group and Rh status, antibody screen, infection screening as per preconception counselling
  • urine R&B, midstream urine C&S
  • screen for bacteriuria and proteinuria
• pelvic exam
  • Pap smear (only if required according to patient history and provincial screening guidelines), cervical or urine PCR for N gonorrhoeae (GC) and C. trachomatis

Nausea and Vomiting

Epidemiology

• affects 50-90% of pregnant women
• often limited to T1 but may persist beyond this
Management
- rule out other causes of N/V
- weigh frequently, assess level of hydration, test urine for ketones
- non-pharmacological
  - avoid mixing fluids and solids, frequent small meals (bland, dry, salty are better tolerated)
  - electrolyte oral solutions (Pedialyte®, Gatorade®)
  - stop prenatal vitamins
  - increase sleep/rest
  - ginger (maximum 1,000 mg/d)
  - acupuncture, acupressure
- pharmacological
  - first line: Diclectin® (10 mg doxylamine succinate with vitamin B6) 4 tablets PO daily (1 q am, 1 q lunch and 2 qhs) up to maximum of 8 tablets/day
  - if no improvement, try dimenhydrinate (50-100 mg q4-6h PO), followed by hydroxyzine, pyridoxine, phenothiazine, or metoclopramide
  - vitamin B6 lollipops
  - if patient dehydrated, assess fluid replacement needs and resuscitate accordingly
- severe/refractory
  - consider homecare with IV fluids and parenteral anti-emetics, hospitalization

Hyperemesis Gravidarum

Definition
- intractable N/V, usually presents in T1 then diminishes; occasionally persists throughout pregnancy
- affects ~1% of pregnancies

Etiology
- multifactorial with hormonal, immunologic, and psychological components
- rapidly rising β-hCG ± estrogen levels may be implicated

Investigations
- rule out systemic causes: GI inflammation, pyelonephritis, thyrotoxicosis
- rule out other obstetrical causes: multiple gestation, GTN, HELLP syndrome
- CBC, electrolytes, BUN, creatinine, LFTs, urinalysis
- ultrasound

Management
- thiamine supplementation may be indicated
- non-pharmacological (see Nausea and Vomiting)
- pharmacological options
  - Diclectin® (for dosage, see Nausea and Vomiting)
  - Dimenhydrinate can be safely used as an adjunct to Diclectin® (1 suppository bid or 25 mg PO qid)
  - other adjuncts: hydroxyzine, pyridoxine, phenothiazine, metoclopramide
  - also consider: ondansetron or methylprednisolone
  - if severe: admit to hospital, NPO initially then small frequent meals; correct hypovolemia, electrolyte disturbance, and ketosis; TPN (if very severe) to reverse catabolic state

Complications
- maternal
  - dehydration, electrolyte and acid-base disturbances
  - Mallory-Weiss tear
  - Wernicke’s encephalopathy, if protracted course
  - death
- fetal: usually none, IUGR is 15x more common in women losing >5% of pre-pregnancy weight

Subsequent Prenatal Visits

Timing
- for uncomplicated pregnancies, SOGC recommends q4-6 wk until 30 wk, q2-3 wk from 30 wk, and q1-2 wk from 36 wk until delivery

Assess at Every Visit
- estimated GA
- history: fetal movements, uterine bleeding, leaking, cramping, questions, concerns
- physical exam: BP, weight gain, SFH, Leopold’s maneuvers (T3) for lie, position, and presentation of fetus
- investigations: urinalysis for glucosuria and proteinuria in high risk women; fetal heart rate starting at 10-12 wk using Doppler U/S
**Leopold’s Maneuvers**
- performed after 30-32 wk gestation
- first maneuver: to determine which fetal part is lying furthest away from the pelvic inlet
- second maneuver: to determine the location of the fetal back
- third maneuver: to determine which fetal part is lying above the pelvic inlet
- fourth maneuver: to locate the fetal brow

Figure 2. Leopold’s maneuvers (T3)

---

**Prenatal Screening and Diagnostic Tests**

**Screening Tests**
- testing should only occur following counselling and with informed consent from the patient

**Table 2. High-Risk Population Screening Tests**

<table>
<thead>
<tr>
<th>Disease (Inheritance)</th>
<th>Population(s) at Risk</th>
<th>Screening Test(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Thalassemia (AR)</td>
<td>Mediterranean, South East Asian, Western Pacific, African, Middle Eastern, Caribbean, South American</td>
<td>CBC (MCV and MCH), Hb electrophoresis, or HPLC</td>
</tr>
<tr>
<td>Sickle Cell (AR)</td>
<td>African, Caribbean, Mediterranean Middle Eastern, Indian, South American</td>
<td>CBC (MCV and MCH), Hb electrophoresis, or HPLC</td>
</tr>
<tr>
<td>Cystic Fibrosis (CF)  (AR)</td>
<td>Family history of CF in patient or partner or medical condition linked to CF like male infertility</td>
<td>CFTR gene DNA analysis</td>
</tr>
<tr>
<td>Tay Sachs Disease (AR)</td>
<td>Ashkenazi Jewish*, French Canadians, Cajun</td>
<td>Enzyme assay HEXA, or DNA analysis HEXA gene</td>
</tr>
<tr>
<td>Fragile X Syndrome (X-linked)</td>
<td>Family history – confirmed or suspected</td>
<td>DNA analysis: FMR-1 gene</td>
</tr>
</tbody>
</table>

AR = autosomal recessive; HEXA = hexosaminidase A; HPLC = high performance liquid chromatography
*If both partners are Ashkenazi Jewish, test for Canavan disease and Familial Dysautonomia (FD); if family history of a specific condition, look for carrier status: e.g. Gaucher, CF, Bloom syndrome, Niemann-Pick disease, etc. In all cases, if both partners are positive, refer for genetic counseling.

</tbody>
</table>

Maternal serum screen is also referred to as Triple Screen; if Inhibin A is also tested, it is referred to as Quadruple Screen

ULTRASOUND SCREENING
8-12 wk GA: dating ultrasound (most accurate form of pregnancy dating)
- measurement of crown-rump length (margin of error: ± 5 d)
- change EDC to U/S date if >5 d discrepancy from EDC based on LMP
11-14 wk GA: NTUS
- measures the amount of fluid behind the neck of the fetus
- early screen for Trisomy 21 (may also detect cardiac and other aneuploidies like Turner’s syndrome)
- NT measurement is necessary for the FTS and IPS Part 1
18-20 wk GA: growth and anatomy U/S (margin of error: ± 10 d)
- earlier or subsequent ultrasounds performed when medically indicated

NON-INVASIVE PRENATAL TESTING (NIPT)
- analyses maternal blood for circulating cell free fetal DNA (ccffDNA) at 10 wk GA onwards. Requires dating ultrasound for accuracy

Advantage
- in high risk women (>age 35) highly sensitive for Trisomy 21 (>99.5%), specificity (>99.8%) - can also look for trisomy 18, 13 and some X and Y disorders as well as common microdeletions
- not harmful to the pregnancy, results available in 7-10 day

Disadvantages
- does not screen for ONTD
- high cost to patient (only covered in some provinces in certain cases)
- unclear how accurate yet in low risk women (<35)
- need to confirm with invasive testing
- does not test for all aneuploidy

Table 4. Comparison of FTS, MSS, and IPS

<table>
<thead>
<tr>
<th>FTS</th>
<th>MSS</th>
<th>IPS</th>
</tr>
</thead>
<tbody>
<tr>
<td>11-14 wk</td>
<td>15-20 wk</td>
<td>11-13 wk U/S-Nuchal Translucency&lt;br&gt;11-14 wk: FTS blood&lt;br&gt;15-20 wk: MSS blood including inhibin</td>
</tr>
<tr>
<td>Risk estimate for 1. Down syndrome (Trisomy 21): increased NT, increased β-hCG, decreased PAPP-A&lt;br&gt;2. Trisomy 18: increased NT, decreased PAPP-A, decreased β-hCG</td>
<td>Risk estimate for 1. ONTD: increased MSAFP (sensitivity 80-90%)&lt;br&gt;2. Trisomy 21: decreased MSAFP, increased β-hCG, decreased μE3 (sensitivity 65%)&lt;br&gt;3. Trisomy 18: decreased MSAFP, decreased β-hCG, decreased μE3, decreased inhibin (sensitivity 80%)&lt;br&gt;Only offered alone if patient missed the time window for FTS or FTS&lt;br&gt;8% baseline false positive rate for Trisomy 21, lower for NTD and Trisomy 18&lt;br&gt;Patients with positive screen should be offered U/S, amniocentesis, or NIPT (covered in some provinces, self-pay in others)</td>
<td>Risk estimate for ONTD, Trisomy 21, Trisomy 18&lt;br&gt;Sensitivity ~85-90%&lt;br&gt;2% false positive rate&lt;br&gt;Patients with positive screen should be offered U/S and/or amniocentesis or NIPT (covered in some provinces, self-pay in others)</td>
</tr>
</tbody>
</table>

Note: In twins, FTS, MSS, and IPS are not applicable; screen with NT, NIPT for chromosomal abnormalities and MSAFP for ONTDs
Diagnostic Tests

Indications
- age >35 yr (increased risk of chromosomal anomalies)
- risk factors in current pregnancy
- abnormal U/S
- abnormal prenatal screen (IPS, FTS, or MSS)
- past history/family history of
  - chromosomal anomaly or genetic disease
  - either parent a known carrier of a genetic disorder or balanced translocation
  - consanguinity
  - >3 spontaneous abortions

AMNIOCENTESIS
- U/S-guided transabdominal extraction of amniotic fluid

Indications
- identification of genetic anomalies (15-16 wk gestation) as per indications above
- confirmation of positive NIPT testing
- positive FTS/IPS
- assessment of fetal lung maturity (T3) via the L/S ratio (lecithin:sphingomyelin)
  - if >2:1, RDS is less likely to occur

Advantages
- also screens for ONTD (acetylcholinesterase and amniotic AFP) – 96% accurate
- in women >35 yr, the risk of chromosomal anomaly (1/180) is greater than the risk of miscarriage from the procedure
- more accurate genetic testing than CVS

Disadvantages
- 1/200 risk of procedure related pregnancy loss, 1/100 for multiple gestations
- results take 14-28 d; QF-PCR or FISH can be done on chromosomes X, Y, 21, 22, 13, 18 to give preliminary results in 48 h

CHORIONIC VILLUS SAMPLING
- biopsy of fetal-derived chorion using a transabdominal needle or transcervical catheter at 10-12 wk

Advantages
- enables pregnancy to be terminated earlier than with amniocentesis
- rapid karyotyping and biochemical assay within 48 h, including FISH analysis
- high sensitivity and specificity

Disadvantages
- 1-2% risk of procedure related pregnancy loss
- does not screen for ONTD
- 1-2% incidence of genetic mosaicism “false negative” results

ISOIMMUNIZATION SCREENING

Definition
- isoimmunization: antibodies (Ab) produced against a specific RBC antigen (Ag) as a result of antigenic stimulation with RBC of another individual

Etiology
- maternal-fetal circulation normally separated by placental barrier, but sensitization can occur and can affect the current pregnancy, or more commonly, future pregnancies
- anti-Rh Ab produced by a sensitized Rh-negative mother can lead to fetal hemolytic anemia
- risk of isoimmunization of an Rh-negative mother with an Rh-positive ABO-compatible infant is 16%
- sensitization routes
- incompatible blood transfusions
- previous fetal-maternal transplacental hemorrhage (e.g. ectopic pregnancy, abortion)
- invasive procedures in pregnancy (e.g. prenatal diagnosis, cerclage, D&C)
- any type of abortion
- labour and delivery

Investigations
- screening with indirect Coombs test at first visit for blood group, Rh status, and antibodies
- Kleihauer-Betke test used to determine extent of fetomaternal hemorrhage by estimating volume of fetal blood volume that entered maternal circulation
- detailed U/S for hydrops fetalis
• MCA dopplers are done to assess degree of fetal anemia; if not available, bilirubin is measured by serial amniocentesis to assess the severity of hemolysis
• cordocentesis for fetal Hb should be used cautiously (not first line)

**Prophylaxis**
- exogenous Rh IgG (Rhogam® or WinRho®) binds to Rh antigens of fetal cells and prevents them from contacting maternal immune system
- Rhogam® (300 µg) given to all Rh negative and antibody screen negative women in the following scenarios:
  - routinely at 28 wk GA (provides protection for ~12 wk)
  - within 72 h of the birth of an Rh positive fetus
  - with any invasive procedure in pregnancy (CVS, amniocentesis)
  - in ectopic pregnancy
  - with miscarriage or therapeutic abortion
  - with an antepartum hemorrhage
  - with trauma
- a Kleihauer-Betke test or Flow cytometry can be used to determine whether more than 300 µg of RhIg is required (>30 mL fetal blood)
- if Rh negative and Ab screen positive, follow mother with serial monthly Ab titres throughout pregnancy ± ultrasounds as needed (Rhogam® has no benefit)

**Treatment**
- falling biliary pigment warrants no intervention (usually indicative of either unaffected or mildly affected fetus)
- intrauterine transfusion of O-negative pRBCs may be required for severely affected fetus or early delivery of the fetus for exchange transfusion

**Complications**
- anti-Rh IgG can cross the placenta and cause fetal RBC hemolysis resulting in fetal anemia, CHF, edema, ascites
- severe cases can lead to fetal hydrops (edema in at least two fetal compartments due to fetal heart failure secondary to anemia) or erythroblastosis fetalis (moderate to severe immune-mediated hemolytic anemia)

---

**Counselling of the Pregnant Woman**

**Nutrition**
- Canada’s Food Guide to Healthy Eating suggests
  - 3-4 servings of milk products daily (greater if multiple gestation)
  - a daily caloric increase of ~100 cal/d in the 1st trimester, ~300 cal/d in the second and third trimesters and ~450 cal/d during lactation
  - daily multivitamin should be continued in the 2nd trimester for women who do not consume an adequate diet; otherwise, routine vitamin supplementation is not necessary (avoid excess vitamin A)
- nutrients important during pregnancy
  - folate: 0.4 mg/d for first 12 wk (5 mg/d if high risk)
  - foods rich in folic acid include: spinach, lentils, chick peas, asparagus, broccoli, peas, brussels sprouts, corn, and oranges
  - calcium: 1200-1500 mg/d
  - maintains integrity of maternal bones, skeletal development of fetus, breast milk production
  - vitamin D: 1,000 IU
  - promotes calcium absorption
  - iron: 0.8 mg/d in T1, 4.5 mg/d in T2, and >6 mg/d in T3
  - supports maternal increase in blood cell mass, supports fetal and placental tissue
  - required amounts exceed normal body stores and typical intake, and therefore need supplemental iron
  - iron is the only known nutrient for which requirements during pregnancy cannot be met by diet alone (see Iron Deficiency Anemia, OB25)
- essential fatty acids – supports fetal neural and visual development
- contained in vegetable oils, margarines, peanuts, fatty fish

**Caffeine**
- diuretic and stimulant that readily crosses placenta
- less than 300 mg/d is not thought to contribute to miscarriage or preterm birth (ACOG)
- relationship between caffeine and IUGR is unknown (ACOG)
- SOGC states 1-2 cups/d are safe during pregnancy

**Herbal Teas and Preparations**
- not enough scientific information about safety of various herbs and herbal products to recommend their use during pregnancy
- some herbal teas can have toxic or pharmacological effects on the mother or fetus
- chamomile has been reported to exhibit adverse effects on the uterus
- raspberry leaf tea often used at term to promote labour
Foodborne Illnesses

- Microbiological contamination of food may occur through cross-contamination and/or improper food handling
  - Listeriosis (Listeria monocytogenes) and toxoplasmosis (Toxoplasma gondii) are of concern during pregnancy
  - Avoid consumption of raw meats, fish, shellfish, poultry, hotdogs, raw eggs, and unpasteurized dairy products
  - Avoid unpasteurized soft cheeses, deli meats, smoked salmon, and pates as they may be sources of Listeria

- Chemical contamination of food
  - Current guideline for mercury of 0.5 ppm in fish is not considered harmful for the general population, including pregnant women
  - Health Canada advises pregnant women to limit consumption of top predator fish such as shark, swordfish, king mackerel, tilefish

Lifestyle

- Exercise under physician guidance; “talk test” = should be able to speak while exercising; avoid supine position after 20 weeks GA
  - Absolute contraindications
    - Ruptured membranes, preterm labour, hypertensive disorders of pregnancy, incompetent cervix, IUGR, multiple gestations (>3), placenta previa after 28th wk, persistent 2nd or 3rd trimester bleeding, uncontrolled type 1 DM, uncontrolled thyroid disease, or other serious cardiovascular, respiratory, or systemic disorder
  - Relative contraindications
    - Previous preterm birth, mild/moderate cardiovascular or respiratory disorder, anemia (Hb ≤100 g/L), malnutrition or eating disorder, twin pregnancy after 28th wk, other significant medical conditions

- Weight gain: optimal gain depends on pre-pregnancy BMI (varies from 6.8-18.2 kg)
  - General rule: 1-3.5 kg/wk during T1, then 0.45 kg/wk until delivery

- Work: strenuous work, extended hours and shift work during pregnancy may be associated with greater risk of low birth weight, prematurity, and spontaneous abortion
  - Air travel is acceptable in second trimester; airline cut off for travel is 36-38 wk gestation depending on the airline, to avoid giving birth on the plane

- Sexual intercourse: may continue, except in patients at risk for: abortion, preterm labour, or placenta previa; breast stimulation may induce uterine activity and is discouraged in high-risk patients near term

- Smoking: assist/encourage to reduce or quit smoking
  - Increased risk of decreased birth weight, placenta previa/abruption, spontaneous abortion, preterm labour, stillbirth

- Alcohol: no amount of alcohol is safe in pregnancy; encourage abstinence from alcohol during pregnancy; alcohol increases incidence of abortion, stillbirth, and congenital anomalies
  - Fetal alcohol syndrome (see Pediatrics, P24)
  - Cocaine: microcephaly, growth retardation, prematurity, abruptio placentae

- Biopsychosocial considerations: discuss birth plan, offer community maternal resources

Medications

- Most drugs cross the placenta to some extent
- Very few drugs are teratogenic, but very few drugs have proven safety in pregnancy
- Use any drug with caution and only if necessary
- Analgesics: acetaminophen preferable to ASA or ibuprofen

Immunizations

Intrapartum
- administration is dependent on the risk of infection vs. risk of immunization complications
- safe: tetanus toxoid, diphtheria, influenza, hepatitis B, pertussis
- avoid live vaccines (risk of placental and fetal infection): polio, measles/mumps/rubella, varicella
- contraindicated: oral typhoid
- the Public Health Agency of Canada recommends:
  - all pregnant women receive the influenza vaccine
  - all pregnant women at 26 weeks of pregnancy or later, who have not received a dose of pertussis-containing vaccine in adulthood, should receive Tdap vaccination in pregnancy

Postpartum
- rubella vaccine for all non-immune mothers. If they’ve had an adult booster and remain non-immune, they should not be revaccinated
- hepatitis B vaccine should be given to infant within 12 h of birth if maternal status unknown or positive – follow-up doses at 1 and 6 mo
- any vaccine required/recommended is generally safe postpartum

Radiation

- ionizing radiation exposure is considered teratogenic at high doses
  - if indicated for maternal health, should be done
- imaging not involving direct abdominal/pelvic high dosage radiation is not associated with adverse effects
  - higher dosage to fetus: plain x-ray of lumbar spine/abdomen/pelvis, barium enema, CT abdomen, pelvis, lumbar spine
- most investigations involve minimal radiation exposure
- radioactive isotopes of iodine are contraindicated
- no known adverse effects from U/S or MRI (long-term effects of gadolinium unknown, avoid if possible)

Antenatal Fetal Surveillance

Fetal Movements

- Patients will generally first notice fetal movement ("quickening") at 18-20 wk in primigravidas; can occur 1-2 wk earlier in multigravidas; can occur 1-2 wk later if placenta is implanted on the anterior wall of uterus
- If the patient is concerned about decreased fetal movement, she is counselled to choose a time when the fetus is normally active to count movements (usually recommended after 26 wk)
- All high risk women should be told to do FM counts
  - If there is a subjective decrease in fetal movement, try drinking juice, eating, changing position, or moving to a quiet room and count for 2 h; ≥6 movements in 2 h expected
  - If there are <6 movement counts in 2 h, patient should present to labour and delivery triage

Non-Stress Test

Definition

- FHR tracing ≥20 min using an external Doppler to assess FHR and its relationship to fetal movement (see Fetal Monitoring in Labour, OB33)

Indication

- Any suggestion of uteroplacental insufficiency or suspected compromise in fetal well-being

Table 8. Classification of Antepartum Non-Stress Test

</table>

Adapted from: SOGC, Fetal Health Surveillance: Antepartum and Intrapartum Consensus Guideline, September 2007

Operating Characteristics

- False positive rate depends on duration; false negative rate = 0.2-0.3%

Interpretation

- Normal: at least 2 accelerations of FHR >15 bpm from the baseline lasting >15 s in 20 min
- Abnormal: <2 accelerations of FHR in 40 min
- If no observed accelerations or fetal movement in the first 20 min, stimulate fetus (fundal pressure, acoustic/vibratory stimulation) and continue monitoring for 30 min

Biophysical Profile

Definition

- U/S assessment of the fetus ± NST

Indications

- Post-term pregnancy
- Decreased fetal movement
- IUGR
- Any other suggestion of fetal distress or uteroplacental insufficiency
Operating Characteristics
• false positive rate ≤30%, false negative rate = 0.1%

*AFV is a marker of chronic hypoxia, all other parameters indicate acute hypoxia

Interpretation
• 8: perinatal mortality rate 1:1,000; repeat BPP as clinically indicated
• 6: perinatal mortality 31:1,000; repeat BPP in 24 h
• 0-4: perinatal mortality rate 200:1,000; deliver fetus if benefits of delivery outweigh risks

Obstetrical Hemorrhage

Definition
vaginal bleeding from 20 wk to term

Differential Diagnosis
• bloody show (shedding of cervical mucous plug) – most common etiology in T3
• placenta previa
• abruptio placentae – most common pathological etiology in T3
• vasa previa
• cervical lesion (cervicitis, polyp, ectropion, cervical cancer)
• uterine rupture
• other: bleeding from bowel or bladder, abnormal coagulation

</tr>
</tbody>
</table>

Placenta Previa

Definition
• placenta implanted in the lower segment of the uterus, presenting ahead of the leading pole of the fetus
• placental position is described in relation to the internal os as “mm away” or “mm of overlap”

Clinical Features
• PAINLESS bright red vaginal bleeding (recurrent), may be minimized and cease spontaneously but can become catastrophic
• mean onset of bleeding is 30 wk GA, but onset depends on degree of previa
• physical exam
  • do not perform pelvic exam until ruling out placenta previa
  • uterus soft and non-tender
  • presenting fetal part high or displaced
  • FHR usually normal
  • shock/anemia correspond to degree of apparent blood loss

Greater than 20 mm of overlap over the internal os in the third trimester of pregnancy is highly predictive of the need for a C/S. Any degree of overlap after 35 wk is an indication for a C/S.
• complications
  • fetal
    ◆ perinatal mortality low but still higher than with a normal pregnancy
    ◆ prematurity (bleeding often dictates early C/S)
    ◆ intrauterine hypoxia (acute or IUGR)
    ◆ fetal malpresentation
    ◆ PPROM
    ◆ risk of fetal blood loss from placenta especially if incised during C/S
  • maternal
    ◆ <1% maternal mortality
    ◆ hemorrhage and hypovolemic shock, anemia, acute renal failure, pituitary necrosis (Sheehan syndrome)
    ◆ placenta accreta – especially if previous uterine surgery, anterior placenta previa
    ◆ hysterectomy

Investigations
• transvaginal U/S is more accurate than transabdominal U/S at diagnosing placenta previa at any gestational age
• if the placenta lies between 20 mm of overlap and 20 mm away from the internal os after 20 wk, transvaginal ultrasounds should be repeated in the third trimester as continued change in the placental location is likely

Management
• goal: keep pregnancy intrauterine until the risk of delivery < risk of continuing pregnancy
• stabilize and monitor
  ◆ maternal stabilization: large bore IV with hydration, O₂ for hypotensive patients
  ◆ maternal monitoring: vitals, urine output, blood loss, blood work (hematocrit, CBC, INR/PTT, platelets, fibrinogen, FDP, type and cross match)
  ◆ electronic fetal monitoring
  ◆ U/S assessment: when fetal and maternal condition permit, determine fetal viability, gestational age, and placental status/position
• Rhogam® if mother is Rh negative
• determine extent of fetomaternal transfusion so that appropriate dose of Rhogam® can be given
• GA <37 wk and minimal bleeding: expectant management
  ◆ admit to hospital
  ◆ limited physical activity, no douches, enemas, or sexual intercourse
  ◆ consider corticosteroids for fetal lung maturity
  ◆ delivery when fetus is mature or hemorrhage dictates due to maternal or fetal compromise
• GA ≥37 wk, profuse bleeding, or L/S ratio is >2:1 – deliver by C/S

Abruptio Placentae

Definition
• premature partial or total placental detachment caused by bleeding at the decidual-placental interface
• occurring >20 wk gestation

Clinical Features
• classification
  ◆ total (fetal death inevitable) vs. partial
  ◆ external/revealed/apparent: blood dissects downward toward cervix
  ◆ internal/concealed/occult (20%): blood dissects upward toward fetus
  ◆ most are mixed
• presentation
  ◆ usually PAINFUL (80%) vaginal bleeding (bleeding not always present if abruption is concealed), uterine tenderness, uterine contractions/hypertonus
  ◆ pain: sudden onset, constant, localized to lower back and uterus
  ◆ shock/anemia out of proportion to apparent blood loss
  ◆ ± fetal distress, fetal demise (15% present with demise), bloody amniotic fluid (fetal presentation typically normal)
  ◆ ± coagulopathy

Complications
• fetal complications: perinatal mortality 25-60%, prematurity, intrauterine hypoxia
• maternal complications: <1% maternal mortality, DIC (in 20% of abruptions), acute renal failure, anemia, hemorrhagic shock, pituitary necrosis (Sheehan syndrome), amniotic fluid embolus

Investigations
• clinical diagnosis, U/S not sensitive for diagnosing abruption (sensitivity = 15%)

Management
• maternal stabilization: large bore IV with hydration, O₂ for hypotensive patients
• maternal monitoring: vitals, urine output, blood loss, blood work (hematocrit, CBC, PTT/PT, platelets, fibrinogen, FDP, type and cross match)
• EFM
• blood products on hand (red cells, platelets, cryoprecipitate) because of DIC risk
• Rhogam® if Rh negative
  • Kleihauer-Betke test may confirm abruption
• mild abruption
  • GA <37 wk: use serial Hct to assess concealed bleeding, deliver when fetus is mature or when hemorrhage dictates
  • GA ≥37 wk: stabilize and deliver
• moderate to severe abruption
  • hydrate and restore blood loss and correct coagulation defect if present
  • vaginal delivery if no contraindication and no evidence of fetal or maternal distress or fetal demise
  • C/S if live fetus and fetal or maternal distress develops with fluid/blood replacement, labour fails to progress, or if vaginal delivery otherwise contraindicated

**Vasa Previa**

**Definition**
• unprotected fetal vessels pass over the cervical os; associated with velamentous insertion of cord into membranes of placenta or succenturiate (accessory) lobe

**Epidemiology**
• 1 in 5 000 deliveries – higher in twin pregnancies

**Clinical Features**
• PAINLESS vaginal bleeding and fetal distress (tachy-to-bradyarrhythmia in a sinusoidal pattern)
• if undiagnosed, 50% perinatal mortality, increasing to 75% if membranes rupture (most infants die of exsanguination)
• if diagnosed antenatally on ultrasound without labour or symptoms, then 97% survival

**Investigations**
• Apt test (NaOH mixed with the blood) can be done immediately to determine if the source of bleeding is fetal (supernatant turns pink) or maternal (supernatant turns yellow)
• Wright stain on blood smear and look for nucleated red blood cells (in cord, not maternal blood)

**Management**
• emergency C/S (since bleeding is from fetus, a small amount of blood loss can have catastrophic consequences)

**Obstetrical Complications**

**Preterm Labour**

**Definition**
• labour between 20 and 37 wk gestation

**Etiology**
• idiopathic (most common)
• maternal: infection (recurrent pyelonephritis, untreated bacteriuria, chorioamnionitis), HTN, DM, chronic illness, mechanical factors; previous obstetric, gynecological, and abdominal surgeries; socio-environmental (poor nutrition, smoking, drugs, alcohol, stress)
• maternal fetal: PPROM (common), polyhydramnios, placenta previa, placental abruption, or placental insufficiency
• fetal: multiple gestation, congenital abnormalities of fetus, fetal hydrops, stress
• uterine: excessive enlargement (hydramnios, multiple gestation), malformations (intracavitary leiomyomas, septate uterus, mullerian duct abnormalities)

**Epidemiology**
• preterm labour complicates about 10% of pregnancies

**Risk Factors**
• prior history of spontaneous PTL is the most important risk factor
• prior history of large or multiple cervical excisions (cone biopsy) or mechanical dilatation (D&C)
• cervical length: measured by transvaginal U/S (cervical length >30 mm has high negative predictive value for PTL before 34 wk)
• identification of bacterial vaginosis and ureaplasma urealyticum infections; routine screening not supported by current data, but it is reasonable to screen high risk women
• family history of preterm birth
• smoking
• late maternal age
• multiple gestation
Predicting PTL
- fetal fibronectin: a glycoprotein in amniotic fluid and placental tissue
  - positive if >50 ng/mL; NPV > PPV
  - in symptomatic women (i.e. preterm contractions), fetal fibronectin is most effectively combined
    with U/S detecting cervical length
  - if cervical length is not short and fetal fibronectin is negative, preterm labour is highly unlikely

Clinical Features
- regular contractions (2 in 10 min, >6/h)
- cervix >1 cm dilated, >80% effaced, or length <2.5 cm

Management
A. Initial
- transfer to appropriate facility if stable
- hydration (NS at 150 mL/h)
- bed rest in LLDP
- sedation (morphine)
- avoid repeated pelvic exams (increased infection risk)
- U/S examination of fetus (GA, BP, position, placenta location, estimated fetal weight)
- prophylactic antibiotics; (for GBS) important to consider if PPROM (e.g. erythromycin controversial, but may help to delay delivery)

B. Suppression of Labour – Tocolysis
- does not inhibit preterm labour completely but may delay delivery (used for <48 h) to allow for
  - betamethasone valerate (Celestone®) and/or transfer to appropriate centre for care of the premature
  - requirements (all must be satisfied)
    - preterm labour
    - live, immature fetus, intact membranes, cervical dilatation of <4 cm
    - absence of maternal or fetal contraindications
  - contraindications
    - maternal: bleeding (placenta previa or abruption), maternal disease (HTN, DM, heart disease), preclampsia or eclampsia, chorioamnionitis
    - fetal: erythroblastosis fetalis, severe congenital anomalies, fetal distress/demise, IUGR, multiple gestation (relative)
  - agents
    - calcium channel blockers: nifedipine
      - 20 mg PO loading dose followed by 20 mg PO 90 min later
      - 20 mg can be continued q3-8h for 72 h or to a max of 180 mg
      - 10 mg PO q20min x 4 doses
    - contraindications: nifedipine allergy, hypotension, heart dysfunction, concurrent beta-mimetics or MgSO₄ use, transdermal nitrates, or other antihypertensive medications
    - prostaglandin synthesis inhibitors: indomethacin
      - 1st line for early preterm labour (<30 wk GA) or polyhydramnios
      - 50-100 mg PR loading dose followed by 50 mg q6h x 8 doses for 48 hours
    - magnesium sulphate
      - was previously used for tocolysis; currently, only indicated for prevention of eclampsia or for neuroprotection if preterm delivery is inevitable between 24 and 34+6 wks GA for neuroprotection
      - 4 g IV loading dose followed by 1 g q1h maintenance until birth

C. Enhancement of Fetal Pulmonary Maturity
- betamethasone valerate (Celestone®) 12 mg IM q24h x 2 doses or dexamethasone 6 mg IM q12h x 4 doses
  - 28-36+6 wk GA: reduces incidence of RDS
  - 24-28 wk GA: reduces severity of RDS, overall mortality and rate of IVH
  - specific maternal contraindications: active TB

D. Cervical Cerclage
- definition: placement of cervical sutures at the level of the internal os, usually at the end of the first trimester or in the second trimester and removed in the third trimester
- indications: cervical incompetence (i.e. cervical dilation and effacement in the absence of increased uterine contractility)
  - emerging evidence indicates that progesterone suppositories are superior to cerclage in preventing preterm labour of singletons not due to cervical incompetence
  - diagnosis of cervical incompetence
    - obstetrical Hx silent cervical dilation, 2nd trimester losses, procedures on cervix
    - ability of cervix to hold an inflated Foley catheter during a hysterosonogram
  - proven benefit in the prevention of PTL in women with primary structural abnormality of the cervix (e.g. osmization of the cervix, connective tissue disorder)

Positive fetal fibronectin in cervicovaginal fluid (>50 ng/mL) at 24 wk gestation predicted spontaneous PTL at <34 wk with sensitivity of 23%, specificity of 97%, PPV of 25%, NPV of 96%

Tocolytics for Preterm Premature Rupture of Membranes
Cochrane OB Syst Rev 2014;2:CD007062
- Purpose: To assess the potential benefits and harms of tocolysis in women with PPROM.
- Selection Criteria: Pregnant women with singleton pregnancies and PPROM (23-36 wk and 6-7 GA).
- Results: 8 studies with 408 women total.
  - Prophylactic tocolysis with PPROM was associated with increased overall latency, without additional benefits for maternal/neonatal outcomes. For women with PPROM before 34 wk, there was a significantly increased risk of chorioamniotitis in women who received tocolysis. Neonatal outcomes were not significantly different.
  - Conclusion: Although there are limitations to the studies, there is currently insufficient evidence to support tocolytic therapy for women with PPROM as there was an increase in maternal chorioamniotitis without significant benefits to the infant.

Cerclage for Short Cervix on Ultrasonography in Women With Singleton Gestations and Previous Preterm Birth
Obstet Gynecol 2011;117:663-671
- Purpose: To determine if cerclage prevents preterm birth (<35 wk gestation) and perinatal mortality and morbidity among women with previous spontaneous preterm birth, asymptomatic singleton gestation, and short cervical length (<25 mm before 24 wk gestation) on transvaginal ultrasonography.
- Methods: Meta-analysis of randomized trials identified using searches on MEDLINE, PUBMED, EMBASE, and the Cochrane Library.
- Results: 5 trials included. Preterm birth was significantly lower among women receiving cerclage vs. those not receiving (RR = 0.70, 95% CI 0.55-0.89). Cerclage also significantly reduced preterm birth before 24, 28, 32, and 37 wk gestation. Perinatal mortality and morbidity were significantly lower in the cerclage group (RR = 0.64, 95% CI 0.45-0.91).
- Conclusions: Cerclage significantly prevents preterm birth and perinatal mortality and morbidity in this specific group of women.

Antenatal Betamethasone for Women at Risk for Late Preterm Delivery
- Purpose: This was a randomized controlled trial comparing betamethasone (n = 1428) to placebo (n = 1420) in the treatment of women with a singleton pregnancy at 34 to 36 + 5/7 wk that were at high risk of delivery. Composite endpoints assessed the need for respiratory support within 72 h of birth were used to measure treatment effectiveness. Specifically, these endpoints included: supplemental oxygen, extrapulmonary membrane oxygenation (ECMO), mechanical ventilation, and CPAP or high-flow nasal canula.
- Results: The primary outcome occurred less frequently in those who received betamethasone (11.6% vs. 14.4%, RR 0.8, p = 0.02). Treatment with betamethasone also significantly reduced additional respiratory complications, bronchopulmonary dysplasia, transient tachypnea of the newborn, and surfactant use.
- Conclusion: Treating women (GA 34 to 36 + 5/7 wk) who are at risk of delivery with betamethasone reduces the risk of neonatal complications.
**Obstetrics**

**Obstetrical Complications**

**Prognosis**
- Prematurity is the leading cause of perinatal morbidity and mortality
- 30 wk or 1,500 g (3.3 lb) = 90% survival
- 33 wk or 2,000 g (4.4 lb) = 99% survival
- Morbidity due to asphyxia, hypoxia, sepsis, RDS, intraventricular cerebral hemorrhage, thermal instability, retinopathy of prematurity, bronchopulmonary dysplasia, necrotizing enterocolitis

**Prevention of Preterm Labour**
- Currently there are no agents approved by Health Canada to arrest preterm labour
- Preventative measures: good prenatal care, identify pregnancies at risk, treat silent vaginal infection or UTIs, patient education
- Transvaginal ultrasound of cervical length is recommended only for high-risk pregnancies and only before 30 weeks GA

**Premature Rupture of Membranes**

**Definitions**
- PROM: pre-labour rupture of membranes at any GA
- Prolonged ROM: >24 h elapsed between rupture of membranes and onset of labour
- Preterm ROM: ROM occurring before 37 wk gestation
- PPROM: preterm (before 37 wk) AND pre-labour rupture of membranes

**Risk Factors**
- Maternal: multiparity, cervical incompetence, infection (cervicitis, vaginitis, STI, UTI), family history of PROM, low socioeconomic class/poor nutrition
- Fetal: congenital anomaly, multiple gestation
- Other risk factors associated with PTL

**Clinical Features**
- History of fluid gush or continued leakage

**Investigations**
- Sterile speculum exam (avoid introduction of infection)
- Pooling of fluid in the posterior fornix
- May observe fluid leaking out of cervix on cough/Valsalva ("cascade")
- Nitrazine (basic amniotic fluid turns nitrazine paper blue)
- Low specificity as it can also be positive with blood, urine, or semen
- Ferning (high salt in amniotic fluid evaporates, looks like ferns under microscope)
- U/S to rule out fetal anomalies; assess GA, presentation, and BPP

**Management**
- Admit for expectant management and monitor vitals q4h, daily BPP and WBC count
- Avoid introducing infection by minimizing examinations
- Consider administration of betamethasone valerate (Celestone®) to accelerate maturity if <34 wk and up to 36-6 weeks if no evidence of infection
- Consider tocolysis for 48 h to permit administration of steroids if PPROM induces labour
- Screen women for UTIs, STIs, GBS infection and treat with appropriate antibiotics if positive (treat GBS at time of labour)
- If not in labour or labour not indicated, consider antibiotics: penicillins or macrolide antibiotics are the antibiotics of choice
- Deliver urgently if evidence of fetal distress and/or chorioamnionitis

**Table 11. PROM Management**

<table>
<thead>
<tr>
<th>Degree of Prematurity</th>
<th>Management</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;24 wk</td>
<td>Consider termination (poor outcome due to pulmonary hypoplasia)</td>

<td>“Grey zone” where risk of death from RDS and neonatal sepsis is the same</td>
</tr>
<tr>
<td>≥37 wk</td>
<td>Induction of labour since the risk of death from sepsis is greater than RDS</td>
</tr>
</tbody>
</table>

**Prognosis**
- Varies with gestational age
- 90% of women with PROM at 28-34 wk GA go into spontaneous labour within 1 wk
- 50% of women with PROM at <26 wk GA go into spontaneous labour within 1 wk
- Complications: cord prolapse, intrapartum infection (chorioamnionitis), premature delivery, limb contracture
Postterm Pregnancy

Definition
- pregnancy >42 wk GA

Epidemiology
- 41 wk GA: up to 27%
- >42 wk GA: 5.5%

Etiology
- most cases idiopathic
- anencephalic fetus with no pituitary gland
- placental sulfatase deficiency (X-linked recessive condition in 1/2,000-1/6,000 infants) – rare

Clinical Features
- postmaturity syndrome (10-20% of post-term pregnancies): fetal weight loss, reduced subcutaneous fat, scaling, dry skin from placental insufficiency, long thin body, open-eyed, alert and worried look, long nails, palms and soles wrinkled
- with increasing GA, higher rates of: intrauterine infection, asphyxia, meconium aspiration syndrome, placental insufficiency, placental aging and infarction, macrosomia, dystocia, fetal distress, operative deliveries, pneumonia, seizures, and requirement of NICU admission, stillbirth

Management
- GA 39 wk with advanced maternal age (>40yo): consideration should be given to IOL due to increased risk of stillbirth
- GA 40-41 wk: expectant management
  - no evidence to support IOL or C/S unless other risk factors for morbidity are present (see prognosis)
- GA >41 wk: offer IOL if vaginal delivery is not contraindicated
  - IOL shown to decrease C/S, fetal heart rate changes, meconium staining, macrosomia, and death when compared with expectant management
- GA >41 wk and expectant management elected: serial fetal surveillance
  - fetal movement count by the mother
  - BPP q3-4d
  - if AFI is decreased, labour should be induced

Prognosis
- if >42 wk, perinatal mortality 2-3x higher (due to progressive uteroplacental insufficiency)
- morbidity increased with HTN in pregnancy, DM, abruption, IUGR, and multiple gestation

Intrauterine Fetal Death (Demise)

Definition
- fetal death in utero after 20 wk GA (before 20 wk GA called spontaneous abortion)

Epidemiology
- occurring in 1% of pregnancies

Etiology
- 50% idiopathic
- 50% secondary to HTN, DM, erythroblastosis fetalis, congenital anomalies, umbilical cord or placental complications, intrauterine infection, APS

Clinical Features
- decreased perception of fetal movement by mother
- SFH and maternal weight not increasing
- absent fetal heart tones on Doppler (not diagnostic)
- high MSAFP
- on U/S: no fetal heart rate. Depending on timing of death, may see skull collapse, brain tissue retraction, empty fetal bladder, non-filled aorta, poor visualization of midline flax

Management
- diagnosis: absent cardiac activity and fetal movement on U/S required for diagnosis
- determine secondary cause
  - maternal: HbA1c, fasting glucose, TSH, Kleihauer-Betke, VDRL, ANA, CBC, anticardiolipins, antibody screens INR/PTT, serum/urine toxicology screens, cervical and vaginal cultures, TORCH screen
  - fetal: karyotype, cord blood, skin biopsy, genetics evaluation, autopsy, amniotic fluid culture for CMV, parvovirus B19, herpes
  - placenta: pathology, bacterial cultures

 DIC: Generalized Coagulation and Fibrinolysis Leading to Depletion of Coagulation Factors

Obstetrical Causes
- Abruption
- Gestational HTN
- Fetal demise
- PPH

DIC-specific Blood Work
- Platelets
- aPTT and PT
- FDP
- Fibrinogen

Treatment
- Treat underlying cause
- Supportive
- Fluids
- Blood products
- FFP, platelets, cryoprecipitate
- Consider anti-coagulation as VTE prophylaxis
Treatment

- <12 wk: dilation and curettage
- 13–20 wk: dilation and evacuation or sometimes IOL
- >20 wk: induction of labour
- monitor for maternal coagulopathy (10% risk of DIC)
- parental psychological care/bereavement support as per hospital protocol
- comprehensive discussion within 3 mo about final investigation and post-mortem results, help make plans for future pregnancies

### Intrauterine Growth Restriction

#### Definition
- infant weight <10th percentile for GA or <2,500 g at term

#### Etiology/Risk Factors
- 50% unknown
- maternal causes
  - malnutrition, smoking, drug abuse, alcoholism, cyanotic heart disease, type 1 DM, SLE, pulmonary insufficiency, previous IUGR (25% risk, most important risk factor), chronic HTN
- maternal fetal
  - any disease causing placental insufficiency
  - includes gestational HTN, chronic renal insufficiency, gross placental morphological abnormalities (infarction, hemangiomas, placenta previa, abnormal cord insertion), prolonged gestation fetal causes
  - TORCH infections, multiple gestation, congenital anomalies/chromosomal abnormalities (10%)

#### Clinical Features
- symmetric/type I (25-30%): occurs early in pregnancy
  - reduced growth of both head and abdomen
  - head:abdomen ratio may be normal (>1 up to 32 wk; =1 at 32-34 wk; <1 after 34 wk GA)
  - usually associated with congenital anomalies or TORCH infections
- asymmetric/type II (70%): occurs late in pregnancy
  - fetal abdomen is disproportionately smaller than fetal head
  - brain is spared, therefore head:abdomen ratio increased
  - usually associated with placental insufficiency
  - more favourable prognosis than type I
- complications
  - prone to meconium aspiration, asphyxia, polycythemia, hypoglycemia, hypocalcemia, hyrophosphatemia, hyponatremia, and mental retardation
  - greater risk of perinatal morbidity and mortality

#### Investigations
- SFH measurements at every antepartum visit
- if mother at high risk or SFH lags >2 cm behind GA
  - U/S for biparietal diameter, head and abdominal circumference ratio, femur length, fetal weight, and AFV (decrease associated with IUGR), decrease in the rate of growth
  - ± BPP
  - Doppler analysis of umbilical cord blood flow

#### Management
- prevention via risk modification prior to pregnancy is ideal
- modify controllable factors: smoking, alcohol, nutrition, and treat maternal illness
- bed rest in LLDP
- serial BPP (monitor fetal growth) and determine cause of IUGR, if possible
- delivery when extrauterine existence is less dangerous than continued intrauterine existence (abnormal function tests, absent growth, severe oligohydramnios) especially if GA >34 wk
- liberal use of C/S since IUGR fetus withstands labour poorly

### Macrosomia

#### Definition
- infant weight >90th percentile for a particular GA or >4,000 g

#### Etiology/Risk Factors
- maternal obesity, GDM, past history of macrosomic infant, prolonged gestation, multiparity

#### Clinical Features
- increased risk of perinatal mortality
- CPD and birth injuries (shoulder dystocia, fetal bone fracture) more common
- complications of DM in labour (see Table 15, OB27)
Investigations
- serial SFH
- further investigations if mother at high risk or SFH > 2 cm ahead of GA
- U/S predictors
  - polyhydramnios
  - third trimester AC > 1.5 cm/wk
  - HC/AC ratio < 10th percentile
  - FL/AC ratio < 20th percentile

Management
- prophylactic C/S is a reasonable option where EFW > 5,000 g in non-diabetic woman and EFW > 4,500 g in diabetic woman
- no evidence that prophylactic C/S improves outcomes
- risks and benefits of early induction (risk of C/S vs. risk of dystocia) must be weighed in diabetic mothers, as current research is unclear

**Polyhydramnios/Oligohydramnios**

<table>
<thead>
<tr>
<th>Polyhydramnios</th>
<th>Oligohydramnios</th>
</tr>
</thead>
</table>
| **Definition** | AFI > 25 cm  
U/S: single deepest pocket > 8 cm | AFI < 5 cm  
U/S: single deepest pocket ≤ 2 cm |
| **Etiology** | Idiopathic most common  
Maternal  
Type 1 DM: abnormalities of transchorionic flow  
Maternal-fetal  
Chorioangiomas  
Multiple gestation  
Fetal hydrops (increased erythroblastosis)  
Fetal  
Chromosomal anomaly (up to 2/3 of fetuses have severe polyhydramnios)  
Respiratory: cystic adenomatoid malformation lung  
CNS: anencephaly, hydrocephalus, meningocoele  
GI: tracheoesophageal fistula, duodenal atresia, facial clefts (interfere with swallowing) | Idiopathic most common  
Maternal  
Uteroplacental insufficiency (preeclampsia, nephropathy)  
Medications (ACEI)  
Fetal  
Congenital urinary tract anomalies (renal agenesis, obstruction, posterior urethral valves)  
UGR  
Ruptured membranes: prolonged amniotic fluid leak  
Amniotic fluid normally decreases after 35 wk |
| **Epidemiology** | Occur in 0.2-1.6% of all pregnancies | Occur in ~ 4.5% of all pregnancies  
Severe form in < 0.7%  
Common in pregnancies > 41 wk (~ 12%) |
| **Clinical Features and Complications** | Uterus large for dates, difficulty palpating fetal parts and hearing FHR  
Maternal complications  
Pressure symptoms from overstretched uterus (dyspnea, edema, hydrocephrosis)  
Obstetrical complications  
Cord prolapse, placental abruption, malpresentation, preterm labour, uterine dysfunction, and PPH | Uterus small for dates  
Fetal complications  
15-25% have fetal anomalies  
Amniotic fluid bands (T1) can lead to Potter’s facies, limb deformities, abdominal wall defects  
Obstetrical complications  
Cord compression  
Increased risk of adverse fetal outcomes  
Pulmonary hypoplasia (late-onset)  
Marker for infants who may not tolerate labour well |
| **Management** | Determine underlying cause  
Screen for maternal disease/infection  
Complete fetal U/S evaluation  
Depends on severity  
Mild to moderate cases require no treatment  
If severe, hospitalize and consider therapeutic amniocentesis | Always warrants admission and investigation  
Rule out ROM  
Fetal monitoring (NST, BPP)  
U/S Doppler studies (umbilical cord and uterine artery)  
Maternal hydration with oral or IV fluids to help increase amniotic fluid  
Injection of fluid via amniocentesis will improve condition for ~ 1 wk – may be most helpful for visualizing any associated fetal anomalies  
Consider delivery if term  
Amnio-infusion may be considered during labour via intrauterine catheter |
| **Prognosis** | 2-5 fold increase in risk of perinatal mortality | Poorer with early onset  
High mortality related to congenital malformations and pulmonary hypoplasia when diagnosed during T2 |
Multi-Fetal Gestation and Malpresentation

Epidemiology
- incidence of twins is 1/80 and triplets 1/6,400 in North America
- 2/3 of twins are dizygotic (fraternal)
  - risk factors for dizygotic twins: IVF, increased maternal age, newly discontinued OCP, ethnicity (e.g. certain African regions)
- monozygous twinning occurs at a constant rate worldwide (1/250)
- determine zygosity by number of placentas, thickness of membranes, sex, blood type

Clinical Features

</tr>
</tbody>
</table>

Management
- U/S determination of chorionicity must be done within first trimester (ideally 8-12 wk GA)
- increased antenatal surveillance
  - serial U/S q 2-3wk from 24 wk GA to assess growth (uncomplicated diamniotic dichorionitic)
  - increased frequency of ultrasounds in monochorionic diamniotic and monochorionic monoamniotic twins
  - Doppler flow studies weekly if discordant fetal growth (>30%)
  - BPP as needed
- may attempt vaginal delivery if twin A presents as vertex, otherwise C/S (40-50% of all twin deliveries, 15% of cases have twin A delivered vaginally and twin B delivered by C/S)
- mode of delivery depends on fetal weights, GA, presentation

### The Ps of Multiple Gestation Complications

- increased rates of
  - Puking
  - Pallor (anemia)
  - Preclampsia/PIH
  - Pressure (compressive symptoms)
  - PTL, PROM, PPH
  - Polyhydramnios
  - Placenta previa/abruption
  - PP/H/A
  - Prolonged labour
  - Cord prolapse
  - Prematurity
  - Malpresentation
  - Perinatal morbidity and mortality
  - Parental distress
  - Postpartum depression

### Figure 4. Classification of twin pregnancies

- *Indicates time of cleavage

---

- Monoamnionic Monochorionic (forked cord)
- Monoamnionic Monochorionic *9-12 d*
- Monoamnionic Monochorionic (one cord)
- Diamnionic Dichorionic (fused) *0-72 h*
- Diamnionic Dichorionic (separated)
- Diamnionic Monochorionic *4-8 d*
**Twin-Twin Transfusion Syndrome**

**Definition**
- formation of placental intertwin vascular anastomoses causes arterial blood from donor twin to pass into veins of the recipient twin

**Epidemiology**
- 10% of monochorionic twins
- concern if >30% discordance in estimated fetal weight

**Clinical Features**
- donor twin: IUGR, hypovolemia, hypotension, anemia, oligohydramnios
- recipient twin: hypervolemia, HTN, CHF, polycythemia, edema, polyhydramnios, kernicterus in neonatal period

**Investigations**
- detected by U/S screening, Doppler flow analysis

**Management**
- therapeutic serial amniocentesis to decompress polyhydramnios of recipient twin and decrease pressure in cavity and on placenta
- intrauterine blood transfusion to donor twin if necessary
- laparoscopic occlusion of placental vessels
- fetoscopic laser ablation of placental vascular anastomoses when indicated and if available

---

**Breech Presentation**

**Definition**
- fetal buttocks or lower extremity is the presenting part as determined on U/S
- complete (10%): hips and knees both flexed
- frank (60%): hips flexed, knees extended, buttocks present at cervix
  - most common type of breech presentation
  - most common breech presentation to be delivered vaginally
- incomplete (30%): both or one hip flexed and both or one knee present below the buttocks, feet or knees present first (footling breech, kneeling breech)

**Epidemiology**
- occurs in 3-4% of pregnancies at term (25% <28 wk)

**Risk Factors**
- maternal: pelvis (contracted), uterus (shape abnormalities, intrauterine tumours, fibroids, previous breech), pelvic tumours causing compression, grand multiparity
- maternal-fetal: placenta (previa), amniotic fluid (poly-/oligohydramnios)
- fetal: prematurity, multiple gestation, congenital malformations (found in 6% of breeches; 2-3% if in vertex presentations), abnormalities in fetal tone and movement, aneuploidy, hydrocephalus, anencephalus

**Management**
- ECV: repositioning of singleton fetus within uterus under U/S guidance
  - overall success rate of 65%
  - criteria: >36 wk GA, singleton, unengaged presenting part, reactive NST, not in labour
  - contraindications: previous T3 bleed, prior classical C/S, previous myomectomy, oligohydramnios, PROM, placenta previa, abnormal U/S, suspected IUGR, HTN, uteroplacental insufficiency, nuchal cord
  - risks: abruption, cord compression, cord accident, ROM, labour, fetal bradycardia requiring C/S (<1% risk), alloimmunization, fetal death (1:5,000)
  - method: tocometry, followed by U/S guided transabdominal manipulation of fetus with constant fetal heart monitoring
  - if patient Rh negative, give Rhogam® prior to procedure
  - better prognosis if multiparous, good fluid volume, small baby, skilled obstetrician, posterior placenta
  - pre- or early-labour ultrasound to assess type of breech presentation, fetal growth, estimated weight, placenta position, attitude of fetal head (flexed is preferable); if ultrasound unavailable, recommend C/S
  - ECV and elective C/S should be presented as options with the risks and benefits outlined; obtain informed consent

---

Criteria for Vaginal Breech Delivery
- Frank or complete breech, GA >36 wk
- EFW 2,500-3,800 g based on clinical and U/S assessment (5.5–8.5 lb)
- Fetal head flexed
- Continuous fetal monitoring
- 2 experienced obstetricians, assistant, and anesthetist present
- Ability to perform emergency C/S within 30 min if required
Hypertensive Disorders of Pregnancy

**Hypertensive Disorders of Pregnancy**

- hypertensive disorders of pregnancy are classified as either pre-existing or gestational HTN

**PRE-EXISTING HYPERTENSION**

**Definition**
- BP >140/90 prior to 20 wk GA, persisting >7 wk postpartum
- essential HTN is associated with an increased risk of gestational HTN, abruptio placentae, IUGR, and IUFD

**GESTATIONAL HTN**

**Definition**
- sBP >140 or dBP >90 developing after 20th wk GA in the absence of proteinuria in a woman known to be normotensive before pregnancy

**Risk Factors**
- maternal factors
  - primigravida (80-90% of gestational HTN), first conception with a new partner, PMHx or FHx of gestational HTN
  - DM, chronic HTN, or renal insufficiency
  - obesity
  - antiphospholipid syndrome
  - extremes of maternal age (<18 or >35 yr)
  - previous stillbirth or IUFD
- fetal factors
  - IUGR or oligohydramnios
  - GTN
  - multiple gestation
  - fetal hydrops “mirror syndrome”

**Clinical Evaluation of HTN in Pregnancy**
- in general, clinical evaluation should include the mother and fetus
- **evaluation of mother**
  - body weight
  - central nervous system
    - presence and severity of headache
    - visual disturbances – blurring, scotomata
    - tremulousness, irritability, somnolence
    - hyperreflexia
  - hematologic
    - bleeding, petechiae
  - hepatic
    - RUQ or epigastric pain
    - severe N/V
  - renal
    - urine output and colour
    - non-dependent edema (i.e. hands and face)

- method for vaginal breech delivery
  - encourage effective maternal pushing efforts
  - at delivery of head (after feet), assistant must apply suprapubic pressure to flex and engage fetal head
  - delivery can be spontaneous or assisted; avoid fetal traction
  - apply fetal manipulation only after spontaneous delivery to level of umbilicus
- C/S recommended if: the breech has not descended to the perineum in the second stage of labour after 2 h, in the absence of active pushing, or if vaginal delivery is not imminent after 1 h of active pushing
- contraindications to vaginal breech delivery
  - cord presentation
  - clinically inadequate maternal pelvis
  - fetal factors incompatible with vaginal delivery (e.g. hydrocephalus, macrosomia, fetal growth restriction)

**Prognosis**
- regardless of route of delivery, breech infants have lower birth weights and higher rates of perinatal mortality, congenital anomalies, abruption, and cord prolapse

**Ominous Symptoms of HTN in Pregnancy**
- RUQ pain, headache, and visual disturbances

**Hypertension in Pregnancy**

**Adverse Maternal Conditions**
- sBP >160 mmHg
- dBP >100 mmHg
- HELLP
- Cerebral hemorrhage
- Renal dysfunction: oliguria <500 mL/d
- Left ventricular failure, pulmonary edema
- Placental abruption, DIC
- Symptoms
- Abdominal pain, N/V
- Headaches, visual prob ems
- SOB, chest pain
- Eclampsia: convulsions

**Adverse Fetal Conditions**
- IUGR
- Oligohydramnios
  - Absent/reversed umbilical artery end diastolic flow
  - Can result in:
    - Fetal disability and/or death

**Vaginal Delivery of Breech Presentation**

**SOGC Clinical Practice Guidelines**
2009;226:557-566.

**Objective**: To discuss risks and benefits of trial of labour versus planned CS, with selection criteria, management, and delivery techniques for trial of vaginal breech birth.

**Evidence**: Randomized trials, prospective cohort studies and select cohort studies from Medline search for long-term outcomes and epidemiology of vaginal breech delivery.

**Summary**: Higher risk of perinatal mortality and short-term neonatal morbidity can be associated with vaginal breech birth as compared to elective C/S. However, careful case selection (including term singleton breech fetuses and clinically adequate maternal pelvis) and labour management may achieve a similar safety level as elective C/S (—2 per 1,000 births perinatal mortality, ~2% short-term neonatal morbidity). Specific protocols for vaginal breech delivery should be followed: continuous fetal heart monitoring, assessment for adequate progress in labour, no induction of labour recommended, emergency C/S available if required, and health care providers with requisite skills and experience. Informed consent for the preferred delivery method should be obtained.
• evaluation of fetus
  - fetal movement
  - fetal heart rate tracing – NST
  - ultrasound for growth
  - BPP
  - Doppler flow studies

Laboratory Evaluation of Gestational Hypertension
• CBC
• PT, INR, fibrinogen – if abnormal LFTs or bleeding
• ALT, AST
• creatinine, uric acid
• 24 h urine collection for protein or albumin:creatinine ratio

Complications
• maternal
  - liver and renal dysfunction
  - seizure "eclampsia"
  - abruptio placentae
  - left ventricular failure/pulmonary edema
  - DIC (release of placental thromboplastin consumptive coagulopathy)
  - HELLP syndrome
  - hemorrhagic stroke (50% of deaths)
  - fetal (2nd to placental insufficiency)
  - IUGR, prematurity, abruptio placentae, IUFD

Management
• for non-severe HTN (149-159/90-105) target a BP of 130-155/80-105 in women without comorbidities or <140/90 in women with comorbidities
• for both pre-existing and gestational HTN, labetalol 100-400 mg PO bid-tid, nifedipine XL preparation 20-60 mg PO od, or a-methyldopa 250-500 mg PO bid-qid
• for severe HTN (BP>160/110), give one of:
  - labetalol 20 mg IV then 20-80 mg IV q30min (max 300 mg) (then switch to oral)
  - nifedipine 5-10 mg capsule q30min
  - hydralazine 5 mg IV, repeat 5-10 mg IV q30min or 0 5 to 10 mg/hr IV, to a maximum of 20 mg IV (or 30 mg IM)
• no ACEI, ARBs, diuretics, prazosin, or atenolol
• pre-existing HTN and gestational HTN without any deterioration can be followed until 37 wk, then decide to induce shortly thereafter

PREECLAMPSIA

Definition
• pre-existing or gestational HTN with new onset proteinuria or adverse conditions

Risk Factors
• nulliparity
• preeclampsia in a previous pregnancy
• age >40 yr or <18 yr
• FHx of preeclampsia
• chronic HTN
• chronic renal disease
• antiphospholipid antibody syndrome or inherited thrombophilia
• vascular or connective tissue disease
• DM (pre-gestational and gestational)
• obesity
• hydrops fetalis “mirror syndrome”
• unexplained fetal growth restriction
• abruptio placentae
• there is a potential for further deterioration to severe preeclampsia as defined above

Management
• depends on GA, possible threat of seizures
• if stable and no adverse factors, may admit and follow, ± decide to deliver as approaching 34-36 wk
  (must weigh risks of fetal prematurity vs. risks of developing severe preeclampsia/eclampsia)
• for severe preeclampsia, stabilize and deliver
• if severe preeclampsia during labour, increase maternal monitoring: hourly input and output, urine dip q12h, hourly neurological vitals, and increase fetal monitoring (continuous FHR monitoring)
• antihypertensive therapy
  - labetalol 20 mg IV, then 20-80 mg IV q30min (max 300 mg) (then switch to oral)
  - nifedipine 5-10 mg capsule q30min
  - hydralazine 5 mg IV, repeat 5-10 mg IV q30min or 0.5 to 10 mg/hr IV, to a maximum of 20 mg IV (or 30 mg IM)

I-A Evidence-Recommendation Highlights of SOGC Clinical Practice Guidelines
Diagnosis, Evaluation, and Management of the Hypertensive Disorders of Pregnancy
• For BP measurement, Korotkoff phase V should be used to designate the dBP.
• Calcium supplementation (if at least 1g/d, orally) is recommended for women with low dietary intake of calcium (<800 mg/d). (I-A)
• For preeclampsia prevention among increased risk women, low-dose “spironolactone” (75-100 mg/d) is recommended until delivery.
• Umbilical artery Doppler velocimetry should be part of the antenatal fetal surveillance in preeclampsia.
• Initial antihypertensive therapy for severe HTN (sBP >160 or dBP >110) should be with labetalol, nifedipine, or hydralazine.
• Initial antihypertensive therapy for non-severe HTN (BP 140-159/90-109 mmHg) should be with methyldopa, β-blockers, or calcium channel blockers.
• Antenatal corticosteroids for fetal lung maturation should be considered for all women with preeclampsia before 34 wk gestation.
• In a planned vaginal delivery with an unfavourable cervix, cervical ripening should be used.
• Oxytocin 5 units IV or 10 units IM should be used as part of the management during the third stage of labour, particularly in the presence of thrombocytopenia or coagulopathy.
• MgSO4 is the recommended first-line treatment for eclampsia.
• MgSO4 is the recommended eclampsia prophylaxis in severe preeclampsia.
• seizure prevention
  ■ MgSO₄
• postpartum management
• risk of seizure highest in first 24 h postpartum – continue MgSO₄ for 12-24 h after delivery
• watch for HELLP syndrome
• most return to a normotensive BP within 2 wk

ECLAMPSIA

Definition
• the occurrence of one or more generalized convulsions and/or coma in the setting of preeclampsia and in the absence of other neurologic conditions

Epidemiology
• an eclamptic seizure occurs in approximately 0.5% of mildly preeclamptic women and 2-3% of severely preeclamptic women

Risk Factors
• same as risk factors for preeclampsia

Clinical Manifestations
• eclampsia is a clinical diagnosis
• typically tonic-clonic and lasting 60-75 s
• symptoms that may occur before the seizure include persistent frontal or occipital headache, blurred vision, photophobia, right upper quadrant or epigastric pain, and altered mental status
• in up to one third of cases, there is no proteinuria or blood pressure <140/90 mmHg prior to the seizure
• in general, women with typical eclamptic seizures who do not have focal neurologic deficits or prolonged coma do not require diagnostic evaluation including imaging

Management
• ABCs
• roll patient into LLDP
• supplemental O₂ via face mask to treat hypoxemia due to hypoventilation during convulsive episode
• aggressive antihypertensive therapy for sustained diastolic pressures ≥105 mmHg or systolic blood pressures ≥160 mmHg with hydralazine or labetalol
• prevention of recurrent convulsions: to prevent further seizures and the possible complications of repeated seizure activity (e.g. rhabdomyolysis, metabolic acidosis, aspiration pneumonitis, etc.)
• MgSO₄ is now the drug of choice, with previously used agents including diazepam and phenytoin
• the definitive treatment of eclampsia is DELIVERY, irrespective of gestational age, to reduce the risk of maternal morbidity and mortality from complications of the disease
• mode of delivery is dependent on clinical situation and fetal-maternal condition

Medical Complications of Pregnancy

</tbody>
</table>

| **Complications**              | Maternal: increased blood volume, N/V, anorexia |
| Fetal: neural tube defects in T1, low birth weight, prematurity |
| **Notes**                      | Mother needs 1 g of elemental iron per fetus; this amount exceeds normal stores + dietary intake |
| Iron requirements increase during pregnancy due to fetal/placental growth (500 mg), increased maternal RBC mass (500 mg) and losses (200 mg) – more needed for multiple gestations |
| **Minimum daily requirement is 0.4 mg** |
| Most often associated with iron deficiency anemia |
| Folic acid is necessary for closure of neural tube during early fetal development (by day 28 of gestation) |
Diabetes Mellitus

Epidemiology
- 2-4% of pregnancies are complicated by DM

Classification of Diabetes Mellitus
- type 1 and type 2 DM (see Endocrinology, E7)
- GDM: onset of DM during pregnancy (usually tested for around 24-28 wk GA)

Etiology
- type 1 and type 2 DM
- GDM: anti-insulin factors produced by placenta and high maternal cortisol levels create increased peripheral insulin resistance → leading to GDM and/or exacerbating pre-existing DM

MANAGEMENT

A. TYPE 1 and TYPE 2 DM

Preconception
- pre-plan and refer to high-risk clinic
- optimize glycemic control
- counsel patient on potential risks and complications
- evaluate for diabetic retinopathy, neuropathy, CAD

Pregnancy
- if already on oral medication, generally switch to insulin therapy
  - continuing glyburide or metformin controversial
  - teratogenicity unknown for other oral anti-hyperglycemics
  - tight glycemic control
  - insulin dosage may need to be adjusted in T2 due to increased demand and increased insulin resistance
  - monitor as for normal pregnancy, plus initial 24 h urine protein and creatinine clearance, retinal exam, HbA1c
    - HbA1c: >140% of pre-pregnancy value associated with increased risk of spontaneous abortion and congenital malformations
  - increased fetal surveillance (BPP, NST), consider fetal ECHO (if high Hgb A1c in first trimester or just prior to pregnancy) to look for cardiac abnormalities

Labour
- timing of delivery depends on fetal and maternal health and risk factors (i.e. must consider size of baby, lung maturity, maternal blood glucose, and blood pressure control)
- can wait for spontaneous labour if blood glucose well-controlled and BPP normal
- induce by 38-39 wk
- type of delivery
  - increased risk of cephalopelvic disproportion (CPD) and shoulder dystocia with babies >4,000 g (8.8 lbs)
  - consider elective C/S for predicted birthweight >4,500 g (9.9 lbs) (controversial)
  - monitoring
    - during labour, monitor blood glucose q1h with patient on insulin and dextrose drip
    - aim for blood glucose between 3.5-6.5 mmol/L to reduce the risk of neonatal hypoglycemia

Postpartum
- insulin requirements dramatically drop with expulsion of placenta (source of insulin antagonists)
- no insulin is required for 48-72 h postpartum in most type 1 DM
- monitor glucose q6h, restart insulin at two-thirds of pre-pregnancy dosage when glucose >8 mmol/L

B. GESTATIONAL DM

Screening and Diagnosis
- all pregnant women between 24-28 wk GA (or at any stage if high risk)
- 2 screening options
  - 1-step screening with fasting 75 g OGTT; GDM if ≥1 of:
    - FPG ≥ 5.1 mmol/L
    - 1h PG ≥ 10.0 mmol/L
    - 2h PG ≥ 8.5 mmol/L
  - 2-step screening (recommended by the Canadian Diabetes Association)
    - Step 1: Perform a random non-fasting 50 g OGCT
      - 1h PG < 7.8 mmol/L is normal
      - 1h PG ≥ 11.1 mmol/L is GDM
    - if 1h PG 7.8-11.0 mmol/L, proceed to Step 2
    - Step 2: Perform a fasting 75 g OGTT, GDM if ≥1 of:
      - FPG ≥ 5.3 mmol/L
      - 1h PG ≥ 10.6 mmol/L
      - 2h PG ≥ 9.0 mmol/L

Monitoring Glucose Levels
- Frequent measurements of blood glucose during pregnancy are advised for women with type 1 or 2 DM to help prevent or treat both hypoglycemia and hyperglycemia, and also improves neonatal outcome
- Aim for:
  - FPG < 5.3 mmol/L (95 mg/dL)
  - 1 h post prandial PG < 7.8 mmol/L (140 mg/dL), 2 h post prandial PG < 6.7 mmol/L (120 mg/dL)
- Most women can be followed with monthly HbA1c determinations

Risk Factors for GDM
- Age > 25 yr
- Obesity
- Ethnicity (Aboriginal, Hispanic, Asian, African)
- FHx of DM
- Previous history of GDM
- Previous child with birthweight > 4.0 kg
- Polycystic ovarian syndrome
- Current use of glucocorticoids
- Essential HTN or pregnancy-related HTN

Post-prandial blood glucose values seem to be the most effective at determining the likelihood of macrosomia or other adverse pregnancy outcomes
Management
- first line is management through diet modification and increased physical activity
- initiate insulin therapy if glycemic targets not achieved within 2 wk of lifestyle modification alone
- glycemic targets: FPG <5.3 mmol/L, 1h PG <7.8 mmol/L, 2h PG <6.7 mmol/L
- oral agents can be used in pregnancy but is off-label and should be discussed with patient
- stop insulin and diabetic diet postpartum
- follow-up with 75 g OGGT by 3 months postpartum, counsel about lifestyle modifications, and perform glucose challenge test q3yr

Prognosis
- most maternal and fetal complications are related to hyperglycemia and its effects

Long-Term Maternal Complications
- type 1 and type 2 DM: risk of progressive retinopathy and nephropathy
- GDM: 50% risk of developing type 2 DM in next 20 yr

Table 15. Complications of DM in Pregnancy

</tbody>
</table>

Group B Streptococcus

Epidemiology
- 15-40% vaginal carrier rate

Risk Factors (for neonatal disease)
- GBS bacteriuria during current pregnancy, even if treated
- previous infant with invasive GBS disease
- preterm labour <37 wk
- ruptured membranes >18 h before delivery
- intrapartum maternal temperature ≥38°C
- positive GBS screen between 35-37 weeks GA in current pregnancy

Clinical Features
- not harmful to mother
- risk of vertical transmission (neonatal sepsis, meningitis or pneumonia, and death)
Investigations
• offer screening to all women at 35-37 wk with vaginal and anorectal swabs for GBS culture

Treatment
• treatment of maternal GBS at delivery decreases neonatal morbidity and mortality
• indications for antibiotic prophylaxis: positive GBS screen, GBS in urine, or previous infant with GBS
disease or GBS status unknown and one of the other risk factors
antibiotics for GBS prophylaxis
  ■ penicillin G 5 million units IV, then 2.5 million units IV q4h until delivery
  ■ penicillin allergic but not at risk for anaphylaxis: cefazolin 2 g IV then 1 g q8h
  ■ penicillin allergic and at risk for anaphylaxis: vancomycin 1 g IV q12h until delivery
• if fever, broad spectrum antibiotic coverage is advised

Urinary Tract Infection

Epidemiology
• most common medical complication of pregnancy
• asymptomatic bacteriuria in 2-7% of pregnant women, more frequently in multiparous women
• note: asymptomatic bacteriuria should be treated in pregnancy due to increased risk of pyelonephritis
  and preterm labour

Etiology
• increased urinary stasis from mechanical and hormonal (progesterone) factors
• organisms include GBS as well as those that occur in non-pregnant women

Clinical Features
• may be asymptomatic
• dysuria, urgency, and frequency in cystitis
• fever, flank pain, and costovertebral angle tenderness in pyelonephritis

Investigations
• urinalysis, urine C&S
• cystoscopy and renal function tests in recurrent infections

Management
• uncomplicated UTI
  ■ first line: amoxicillin (250-500 mg PO q8h x 7 d)
  ■ alternatives: nitrofurantoin (100 mg PO bid x 7 d)
  ■ follow with monthly urine cultures
• pyelonephritis
  ■ hospitalization and IV antibiotics

Prognosis
• complications if untreated: acute cystitis, pyelonephritis, and possible preterm labour
• recurrence is common

<td>VDRL screening for all pregnancies; if positive, requires confirmatory testing</td>
<td>Pen G 2.4 million U IM x 1 dose if early syphilis, 3 doses if late syphilis, monitor VDRL monthly If Pen G allergic: Cindamycin 900 mg IV q4h</td>
</tr>
<tr>
<td>*Toxoplasmosis</td>
<td>Protozoa (toxoplasma gondii)</td>
<td>To mom: raw meat, unpasteurized goat’s milk, cat feces/urine To baby: transplacental</td>
<td>T3 (but most severe if infected in T1); only concern if primary infection during pregnancy</td>
<td>Congenital toxoplasmosis (choorioretinitis, hydrocephaly intracranial calcification, MR, microcephaly) NB: 75% initially asymptomatic at birth</td>
<td>Majority subclinical; may have flu-like symptoms</td>
<td>IgM and IgG serology; PCR of amniotic fluid</td>
<td>Self-limiting in mother; spiramycin decreases fetal morbidity but not rate of transmission</td>
</tr>
</tbody>
</table>

* Indicates TORCH infection
Venous Thromboembolism

Epidemiology
- incidence of 12.1/10,000 (DVT), and 5.4/10,000 (PE)
- increased risk of VTE throughout pregnancy with highest risk of DVT in third trimester and postpartum period; highest risk of PE post-partum (first 6 weeks)

Risk Factors
- previous VTE, age >35, obesity, infection, bedrest/immobility, shock/dehydration, thrombophilias (see Hematology, H35)

Table 17. Risk Factors for VTE Specific to Pregnancy

<table>
<thead>

<tr>
<td></td>
<td>Uturus is mechanical impediment to venous return</td>
<td></td>
</tr>
</tbody>
</table>

Clinical Features
- most DVTs occur in the iliofemoral or calf veins with a predilection for the left leg
- signs of a pulmonary embolism are non-specific (as in non-pregnant women)
- unexplained spontaneous fetal loss

Investigations
- duplex venous Doppler sonography for DVT
- CXR and V/Q scan or spiral CT for PE

Management
- before initiating treatment, obtain a baseline CBC including platelets and aPTT
- warfarin is contraindicated during pregnancy due to its potential teratogenic effects
- unfractionated heparin
  - bolus of 5,000 IU followed by an infusion of ~30 000 IU/24h
  - measure aPTT 6 h after the bolus
  - maintain aPTT at a therapeutic level (1.5-2x normal)
  - repeat q24h once therapeutic
  - heparin-induced thrombocytopenia (HIT) uncommon (3%), but serious complication
  - LMWH can also be used in pregnancy
- compression stockings
- poor evidence to support a recommendation for or against avoidance of prolonged sitting
- VTE prophylaxis
  - women on long-term anticoagulation: full therapeutic anticoagulation throughout pregnancy and for 6-12 wk postpartum
  - women with a non-active PMHx of VTE: unfractionated heparin regimens suggested
  - insufficient evidence in pregnancy to recommend routine use of LMWH for all patients
  - current prophylaxis regimens for acquired thrombophilias (e.g. APS syndrome) include low dose Aspirin® in conjunction with prophylactic heparin

Normal Labour and Delivery

Definition of Labour
- true labour: regular, painful contractions of increasing intensity associated with progressive dilatation and effacement of cervix and descent of presenting part, or progression of station
  - preterm (>20 to <36+6 wk GA)
  - term (37-41+6 wk GA)
  - postterm (>42 wk GA)
- false labour (Braxton-Hicks contractions): irregular contractions, with unchanged intensity and long intervals, occur throughout pregnancy and not associated with any cervical dilatation, effacement, or descent
  - often relieved by rest or sedation
The Cervix

- dilatation: latent phase (0-4 cm, variable time); active phase (4-10 cm)
- effacement: thinning of the cervix by percentage or length of cervix (cm)
- consistency: firm vs. soft
- position: posterior, mid, or anterior
- application: contact between the cervix and presenting part (i.e. well or poorly applied)
- see Bishop Score (Table 22, OB36)

The Fetus

- fetal lie: orientation of the long axis of the fetus with respect to the long axis of the uterus (longitudinal, transverse, oblique)
- fetal presentation: fetal body part closest to the birth canal
  - breech (complete, frank, incomplete) (see Figure 5, OB22)
  - cephalic (vertex/occiput, face, asynclitc, brow)
  - transverse (shoulder)
  - compound (fetal extremity prolapses along with presenting part)
  - all ex. ept vertex are considered malpresentations (see Obstetrical Complications, OB15)
- fetal position: position of presenting part of the fetus relative to the maternal pelvis
  - OA: most common presentation (“normal”) – left OA most common
  - OP: most rotate spontaneously to OA; may cause prolonged second stage of labour
  - OT: leads to arrest of dilatation
    - normally, fetal head enters maternal pelvis and engages in OT position
    - subsequently rotates to OA position (or OP in a small percentage of cases)
- attitude: flexion/extension of fetal head relative to shoulders
  - brow presentation: head partially extended (requires C/S)
  - face presentation: head fully extended
  - mentum posterior always requires C/S, mentum anterior can deliver vaginally
- station: position of presenting bony part relative to ischial spines – determined by vaginal exam
  - at ischial spines = station 0 = engaged
  - -5 to -1 cm above ischial spines or
  - +1 to +5 cm below ischial spines

Maternal Triage Assessment

ID: Age, GPA, EDC, GA, GBS, Rh, Ser CC
HPI: 4 key questions:
- Contractions: Since when, how close (q x min), how long (x s), how painful
- Bleeding: Since when, how much (pads), colour (pink/purplish show vs. brownish vs. bright red = clots), pain?, last U/S, trauma/intercourse? (CDM)
- Fluid (ROM): Since when, large gush vs. trickle, soaked pants? clear vs. green vs. red?, continuous?
- FM: As much as usual?, When last movement?, Kick counts (ie still for 1-2 h, cold juice, feel FM – should have 6 movements in 2 h)

Pregrift: Any complications (HTN, GDM, infections), IPI/FTS screening, last U/S (BPP score, growth/estimated fetal weight, position), last vaginal exam
POBax: Every previous pregnancy and outcome: Year, SVD/CS/miscarriage/abortion, baby size, length of labour, use of vacuum or forceps, complications
PMH, Meds, Allergies, Stx
O/E: Maternal vitals, fetal heart tracing (baseline, variability, presence of accelerations/decelerations), Leopold’s, vaginal exam, U/S

Reference Point for Describing Fetal Position

- Occiput for cephalic presentation
- Sacrum for breech presentation
- Mentum for face presentation

Figure 6. Fetal positions
Four Stages of Labour

First Stage of Labour (0 – 10 cm cervical dilation)
- latent phase
  - uterine contractions typically infrequent and irregular
  - slow cervical dilatation (usually to 4 cm) and effacement
- active phase
  - rapid cervical dilatation to full dilatation (nulliparous ≥1.0 cm/h, multiparous ≥1.2 cm/h)
  - phase of maximum slope on cervical dilatation curve
  - painful, regular contractions q2-3min, lasting 45-60 s
  - contractions strongest at fundus

Second Stage of Labour (10 cm dilation – delivery of the baby)
- from full dilatation to delivery of the baby; duration varies based on parity, contraction quality, and type of analgesia
- mother feels a desire to bear down and push with each contraction
- women may choose a comfortable position that enhances pushing efforts and delivery
  - upright (semi-sitting, squatting) and LLDP are supported in the literature
- progress measured by descent

Third Stage of Labour (delivery of the baby – delivery of the placenta)
- from baby’s birth to separation and expulsion of the placenta
- can last up to 30 min before intervention is indicated
- demonstrated by gush of fresh blood, umbilical cord lengthening, uterine fundus changing shape (firm and globular) and rising upward
- active management: start oxytocin IV drip, or give 10 U IM or 5 mg IV push after delivery of anterior shoulder in anticipation of placental delivery, otherwise give after delivery of placenta
- routine oxytocin administration in third stage of labour can reduce the risk of PPH by >40%

Fourth Stage of Labour
- first postpartum hour
- monitor vital signs and bleeding, repair lacerations
- ensure uterus is contracted (palpate uterus and monitor uterine bleeding)
- inspect placenta for completeness and umbilical cord for presence of 2 arteries and 1 vein
- 3rd and 4th stages of labour most dangerous to the mother (i.e. hemorrhage)

The Cardinal Movements of the Fetus During Delivery

1. Head floating, before engagement
2. Engagement, descent, flexion
3. Further descent, internal rotation
4. Complete rotation, beginning extension
5. Complete extension
6. Restitution (external rotation)
7. Delivery of anterior shoulder
8. Delivery of posterior shoulder

- Fundus rises

Continuous Support for Women During Childbirth
Cochrane DB Syst Rev 2011;16:CD003766
Study: Systematic review of 21 RCTs from 11 countries, 15,061 women in labour.
Intervention: Continuous support during labour vs. usual care.
Outcome: Effects on mothers and their babies.
Results: Continuous intrapartum support increased likelihood of shorter labour, spontaneous vaginal birth, decrease in analgesia use, and a decrease in dissatisfaction with childbirth experience. Greatest benefit when provider is not a healthcare professional. Continuous support was also associated with decreased likelihood to have a Caesarean or instrumental vaginal birth, regional analgesia, or a baby with a low 5 min APGAR score.

Figure 7. Cardinal movements of fetus during delivery
Adapted from illustration in Williams Obstetrics, 19th ed
Analgesic and Anesthetic Techniques in Labour and Birth

• pain or anxiety leads to high endogenous catecholamines, which produce a direct inhibitory effect on uterine contractility

Non-Pharmacologic Pain Relief Techniques
• reduction of painful stimuli
  • maternal movement, position change, counter-pressure, abdominal compression
• activation of peripheral sensory receptors
  • superficial heat and cold
  • immersion in water during labour
  • touch and massage, acupunture, and acupressure
  • TENS
  • intradermal injection of sterile water
  • aromatherapy
• enhancement of descending inhibitory pathways
  • attention focusing and distraction
  • hypnosis
  • music and audio analgesia
  • biofeedback

Pharmacologic Methods (see Anesthesia and Perioperative Medicine, A26)
• nitrous oxide (e.g. self-administered Entonox®)
• narcotics (usually combined with anti-emetic)
• pudendal nerve block
• perineal infiltration with local anesthetic
• regional anesthesia (epidural block, combined spinal-epidural, spinal)

Fetal Monitoring in Labour

• see online Fetal Heart Rate Tutorial

Vaginal Exam
• membrane status, as indicated by amniotic fluid (clear, pink, bloody, meconium)
• cervical effacement (thinning), dilatation, consistency position, application
• fetal presenting part, position, station
• bony pelvis size and shape
• monitor progress of labour at regular intervals and document in a partogram

Intrapartum Fetal Monitoring
• intermittent fetal auscultation with Doppler device q15-30min for 1 min in first stage active phase following a contraction, q5min during second stage when pushing has begun
• continuous electronic FHR monitoring reserved for abnormal auscultation, prolonged labour, labour which is induced or augmented, meconium present, multiple gestation/fetal complication
  • use of continuous electronic monitoring shown to lead to higher intervention rates and no improvement in outcome for the neonate when used routinely in all patients (i.e. no risk factors)
  • techniques for continuous monitoring include external (Doppler) vs. internal (fetal scalp electrode) monitoring
• fetal scalp sampling should be used in conjunction with electronic FHR monitoring and contraction monitoring (CTG) to resolve the interpretation of abnormal or atypical patterns

Electronic FHR Monitoring
• FHR measured by Doppler; contractions measured by tocometer
• described in terms of baseline FHR, variability (short-term, long-term), and periodicity (accelerations, decelerations)
• Baseline FHR
  • normal range is 110-160 bpm
  • parameter of fetal well-being vs. distress
• Variability
  • physiologic variability is a normal characteristic of FHR
  • variability is measured over a 15 min period and is described as: absent, minimal (<6 bpm), moderate (6-25 bpm), marked (>25 bpm)
  • normal variability indicates fetal acid-base status is acceptable
  • can only be assessed by electronic fetal monitoring (CTG)
  • variability decreases intermittently even in healthy fetus
  • see Table 19, OB34

Approach to the Management of Abnormal FHR

POISON – ER
Position (left lateral decubitus position)
O₂ (100% by mask)
IV fluids (corrects maternal hypotension)
Fetal scalp stimulation
Fetal scalp electrode
Fetal scalp pH
Stop oxytocin
Notify MD
Vaginal exam to rule out cord prolapse
Rule out fever, dehydration, drug effects, prematurity
• If above fails, consider C/S
• Periodicity
  • accelerations: increase of ≥15 bpm for ≥15 s, in response to fetal movement or uterine contraction (or ≥10 bpm for ≥10 s if <32 wk GA)
  • decelerations: 3 types, described in terms of shape, onset, depth, duration recovery, occurrence, and impact on baseline FHR and variability

</tbody>
</table>

Variable Decelerations

- Variable in shape, onset, and duration
- Most common type of periodicity seen during labour
- Often with abrupt drop in FHR >15 bpm below baseline (>15 s, <2 min); usually no effect on baseline FHR or variability
- Due to cord compression or, in second stage, forceful pushing with contractions

Complicated Variable Decelerations

- FHR drop <70 bpm for >60 s
- Loss of variability or decrease in baseline after deceleration
- Biphasic deceleration
- Slow return to baseline
- Baseline tachycardia or bradycardia
- May be associated with fetal acidemia

Late Decelerations

- Uniform shape with onset, nadir, and recovery occurring after peak of contraction, slow return to baseline
- May cause decreased variability and change in baseline FHR
- Due to fetal hypoxia and acidemia, maternal hypotension, or uterine hypertonus
- Usually a sign of uteroplacental insufficiency (an ominous sign)

Adapted from SOGC Guidelines, September 2008
*Previous classification was “reassuring” vs. “non-reassuring”, but distinction is now made between tracings that have some concerning changes but do not require immediate action (atypical) versus those with major concerns requiring immediate intervention (abnormal)

Fetal Scalp Blood Sampling
- cervix must be adequately dilated
- indicated when atypical or abnormal fetal heart rate is suggested by clinical parameters including heavy meconium or moderately to severely abnormal FHR patterns (including unexplained low variability, repetitive late decelerations, complex variable decelerations, fetal cardiac arrhythmias)
- done by measuring pH or more recently fetal lactate
  - pH ≥7.25, lactate <4.2 mmol/L: normal, repeat if abnormal FHR persists
  - pH 7.21-7.24, lactate 4.2-4.8 mmol/L: repeat assessment in 30 min or consider delivery if rapid fall since last sample
  - pH ≤7.20, lactate >4.8 mmol/L: indicates fetal acidosis, delivery is indicated
- contraindications
  - known or suspected fetal blood dyscrasia (hemophilia, von Willebrand disease)
  - active maternal infection (HIV, genital herpes)

Fetal Oxygenation
- uterine contractions during labour decrease uteroplacental blood flow, which results in reduced oxygen delivery to the fetus
- most fetuses tolerate this reduction in flow and have no adverse effects
- distribution of oxygen to the fetus depends on maternal, uteroplacental, and fetal factors
- fetal response to hypoxia/asphyxia:
  - decreased movement, tone, and breathing activities
  - anaerobic metabolism (decreased pH)
  - transient fetal bradycardia followed by fetal tachycardia
  - redistribution of fetal blood flow
    - increased flow to brain, heart, and adrenals
    - decreased flow to kidneys, lungs, gut, liver, and peripheral tissues
    - increase in blood pressure

</table>
Induction of Labour

Definition
- artificial initiation of labour in a pregnant woman prior to spontaneous initiation to deliver the fetus and placenta

Prerequisites for Labour Induction
- capability for C/S if necessary
- maternal
  - inducible/ripe cervix: short, thin, soft, anterior cervix with open os
  - if cervix is not ripe, use p ostaglandin vaginal insert (Cervidil*), prostaglandin gel (Prepidil*), misoprostol (Cytotec*) or Foley catheter
- fetal
  - normal fetal heart tracing
  - cephalic presentation
  - adequate fetal monitoring available
  - likelihood of success determined by Bishop score
    - cervix considered unfavourable if <6
    - cervix favourable if ≥6
    - score of 9-13 associated with high likelihood of vaginal delivery

Table 22. Bishop Score

</table>

Indications
- post-dates pregnancy (generally >41 wk) = most common reason for induction
- maternal factors
  - DM = second most common reason for induction
  - gestational HTN
  - other maternal medical problems, e.g. renal or lung disease, chronic hypertension, cholestasis
  - maternal age over 40
- maternal-fetal factors
  - isoimmunization, PROM, chorioamnionitis, post-term pregnancy
- fetal factors
  - suspected fetal jeopardy as evidenced by biochemical or biophysical indications
  - fetal demise, IUGR, oligo/polyhydraminos, anomalies requiring surgical intervention, twins
  - previous stillbirth, low PAPP-A

Risks
- failure to achieve labour and/or vaginal birth
- uterine hyperstimulation with fetal compromise or uterine rupture
- maternal side effects to medications
- uterine atony and PPH

Contraindications
- maternal
  - prior classical or inverted T-incision C/S or uterine surgery (e.g. myomectomy)
  - unstable maternal condition
  - active maternal genital herpes
  - invasive cervical carcinoma
  - pelvic structure deformities
- maternal-fetal
  - placenta previa or vasa previa
  - cord presentation
- fetal
  - fetal distress, malpresentation/abnormal lie, preterm fetus without lung maturity
CERVICAL RIPENING

Definition
- use of medications or other means to soften, efface, and dilate the cervix; increases likelihood of successful induction
- ripening of an unfavourable cervix (Bishop score <6) is warranted prior to induction of labour

Methods
- intravaginal prostaglandin PGE2 gel (Prostin® gel): long and closed cervix
  - recommended dosing interval of prostaglandin gel is every 6-12 h up to 3 doses
  - continuous release; can be removed if needed
  - controlled release PGE2
- intravaginal PGE1 Misoprostol (Cytotec®): long and closed cervix
  - inexpensive, stored at room temperature
  - more commonly used in 2nd trimester termination of pregnancy
- Foley catheter placement to mechanically dilate the cervix

INDUCTION OF LABOUR

Amniotomy
- artificial rupture of membranes (amniotomy) to stimulate prostaglandin synthesis and secretion; may try this as initial measure if cervix is open and soft, the membranes can be felt, and if the head is present at the cervix
- few studies address the value of amniotomy alone for induction of labour
- amniotomy plus intravenous oxytocin: more women delivered vaginally at 24 h than amniotomy alone (relative risk = 0.03) and had fewer instrumental vaginal deliveries (relative risk = 5.5)

Oxytocin
- oxytocin (Pitocin®): 10 U in 1L NS, run at 0.5-2 mU/min IV increasing by 1-2 mU/min q20-60min to a max of 36-48 mU/min
- reduces rate of unsuccessful vaginal deliveries within 24 h when used alone (8.3% vs. 54%, RR 0.16)
- ideal dosing regimen of oxytocin is not known
- current recommendations: use the minimum dose to achieve active labour and increase q30min as needed
- reassessment should occur once a dose of 20 mU/min is reached
- potential complications:
  - hyperstimulation/tetanic contraction (may cause fetal distress or rupture of uterus)
  - uterine muscle fatigue, uterine atony (may result in PPH)
  - vasopressin-like action causing anti-diuresis

Augmentation of Labour
- augmentation of labour is used to promote adequate contractions when spontaneous contractions are inadequate and cervical dilatation or descent of fetus fails to occur
- oxytocin

Abnormalities and Complications of Labour and Delivery

Abnormal Progression of Labour (Dystocia)

Definition
- expected patterns of descent of the presenting part and cervical dilatation fail to occur in the appropriate time frame; can occur in all stages of labour
- during active phase: >4 h of <0.5 cm/h
- during 2nd stage: >1 h with no descent during active pushing

Etiology
- Power (leading cause): contractions (hypotonic, uncoordinated), inadequate maternal expulsive efforts
- Passenger: fetal position, attitude, size, anomalies (hydrocephalus)
- Passage: pelvic structure (CPD), maternal soft tissue factors (tumours, full bladder or rectum, vaginal septum)
- Psyche: hormones released in response to stress may contribute to dystocia; psychological and physiological stress should be evaluated as part of the management once dystocia has been diagnosed
Management
- confirm diagnosis of labour (rule out false labour)
- search for factors of CPD
- diagnosed if adequate contractions measured by intrauterine pressure catheter (IUPC) with no descent/dilatation for >2 h
- management: if CPD ruled out, IV oxytocin augmentation ± amniotomy

Risks of Dystocia
- inadequate progression of labour is associated with an increased incidence of:
  - maternal stress
  - maternal infection
  - postpartum hemorrhage
  - need for neonatal resuscitation
  - fetal compromise (from uterine hyperstimulation)
  - uterine rupture
  - hypotension

Shoulder Dystocia

Definition
- fetal anterior shoulder impacted above symphysis pubis after fetal head has been delivered
- life threatening emergency

Etiology/Epidemiology
- incidence 0.15-1.4% of deliveries
- occurs when breadth of shoulders is greater than biparietal diameter of the head

Risk Factors
- maternal: obesity, DM, multiparity, previous shoulder dystocia
- fetal: prolonged gestation, macrosomia (especially if associated with GDM)
- labour
  - prolonged 2nd stage
  - instrumental midpelvic delivery

Presentation
- "turtle sign": head delivered but retracts against inferior portion of pubic symphysis
- complications
  - fetal
    - hypoxic ischemic encephalopathy (chest compression by vagina or cord compression by pelvis can lead to hypoxia)
    - brachial plexus injury (Erbi's palsy C5-C7; Klumpke's palsy: C8-T1), 90% resolve within 6 mo
    - fracture (clavicle, humerus, cervical spine)
    - death
  - maternal
    - perineal injury
    - PPH (uterine atony lacerations)
    - uterine rupture

Treatment
- goal: to displace anterior shoulder from behind symphysis pubis; follow a stepwise approach of maneuvers until goal achieved
- other options
  - cleidotomy (deliberate fracture of neonatal clavicle)
  - Zavanelli maneuver: replacement of fetus into uterine cavity and emergent C/S
  - symphysiotomy

Prognosis
- 1% risk of long-term disability for infant

Umbilical Cord Prolapse

Definition
- descent of the cord to a level adjacent to or below the presenting part, causing cord compression between presenting part and pelvis

Etiology/Epidemiology
- increased incidence with prematurity/PROM, fetal malpresentation (~50% of cases), low-lying placenta, polyhydramnios, multiple gestation, CPD
- incidence: 1/200-1/400 deliveries

Umbilical Cord Accident Causes
- Nuchal cord
- Type A (looped)
- Type B (hitched)
- Body loop
- Single artery
- True knot
- Torsion
- Velamentous
- Short cord <35 cm
- Long cord >80 cm
**Abnormalities and Complications of Labour and Delivery**

**Presentation**
- visible or palpable cord
- FHR changes (variable decelerations, bradycardia, or both)

**Treatment**
- emergency C/S
- O2 to mother, monitor fetal heart
- alleviate pressure of the presenting part on the cord by elevating fetal head with a pelvic exam (maintain this position until C/S)
- keep cord warm and moist by replacing it into the vagina ± applying warm saline soaks
- roll mom onto all fours
- position mother in Trendelenburg or knee-to-chest position
- if fetal demise or too premature (<22 wk), allow labour and delivery

**Uterine Rupture**

**Etiology/Epidemiology**
- associated with previous uterine scar (in 40% of cases), hyperstimulation with oxytocin, grand multiparity, and previous intrauterine manipulation
- generally occurs during labour, but can occur earlier with a classical incision
- 0.5-0.8% incidence, up to 12% with classical incision

**Presentation**
- prolonged fetal bradycardia – most common presentation
- acute onset of constant lower abdominal pain, may not have pain if receiving epidural analgesia
- hyper/hypotonic uterine contractions
- vaginal bleeding
- intra-abdominal hemorrhage
- sudden loss of fetal descent

**Risk Factors**
- uterine scarring (i.e. previous uterine surgeries including Cesarean (especially classical incision), perforation with D&C, myomectomy)
- excessive uterine stimulation (i.e. protracted labour, oxytocin, prostaglandins)
- uterine trauma (i.e. operative equipment, ECV)
- multiparity
- uterine abnormalities
- placenta accreta

**Treatment**
- rule out placental abruption
- immediate delivery for fetal survival
- maternal stabilization (may require hysterectomy), treat hypovolemia

**Complications**
- maternal mortality 1-10%
- maternal hemorrhage, shock, DIC
- amniotic fluid embolus
- hysterectomy if uncontrollable hemorrhage
- fetal distress, associated with 50% fetal mortality

**Amniotic Fluid Embolus**

**Definition**
- amniotic fluid debris in maternal circulation triggering an anaphylactoid immunologic response

**Etiology/Epidemiology**
- rare intrapartum or immediate postpartum complication
- 60-80% maternal mortality rate, accounts for 10% of all maternal deaths
- leading cause of maternal death in induced abortions and miscarriages
- 1/8,000-1/80,000 births

**Risk Factors**
- placental abruption
- rapid labour
- multiparity
- uterine rupture
- uterine manipulation
Differential Diagnosis
- pulmonary embolus, drug-induced anaphylaxis, septic shock, eclampsia, HELLP syndrome, abruption, chronic coagulopathy

Presentation
- sudden onset of respiratory distress, cardiovascular collapse (hypotension, hypoxia), and coagulopathy
- seizure in 10%
  ARDS and left ventricular dysfunction seen in survivors

Management
- supportive measures (high flow O₂, ventilation support, fluid resuscitation, inotropic support, ± intubation), coagulopathy correction
- ICU admission

Chorioamnionitis

Definition
- infection of the chorion, amnion, and amniotic fluid typically due to ascending infection by organisms of normal vaginal flora

Etiology/Epidemiology
- incidence 1-5% of term pregnancies and up to 25% in preterm deliveries
- predominant microorganisms include: GBS, Bacteroides and Prevotella species, E. coli, and anaerobic Streptococcus
- ascending from vagina

Risk Factors
- prolonged ROM, long labour, multiple vaginal exams during labour, internal monitoring
- bacterial vaginosis and other vaginal infections

Clinical Features
- maternal fever, maternal or fetal tachycardia, uterine tenderness, foul and purulent cervical discharge

Investigations
- CBC: leukocytosis
- amniotic fluid: leukocytes or bacteria

Treatment
- IV antibiotics
  - ampicillin 2 g IV q6h and gentamicin 1.5 mg/kg IV q8h
  - anaerobic coverage (i.e. clindamycin 900 mg IV q8h)
  - expedient delivery regardless of gestational age

Complications
- bacteremia of mother or fetus, wound infection if C/S, pelvic abscess, infant meningitis

Meconium

Epidemiology
- present early in labour in 10% of pregnancies, more common in postdate pregnancies
- in general, meconium may be present in up to 25% of all labours, usually NOT associated with poor outcome, but extra care is required at time of delivery to avoid aspiration. Concern if fluid changes from clear to meconium-stained. Always abnormal if seen in preterm fetus

Etiology
- likely cord compression ± uterine hypertonia
- may indicate undiagnosed breech
- increasing meconium during labour may be a sign of fetal distress

Features
- may be watery or thicker (particulate)
- light yellow/green or dark green-black in colour

Treatment
- call respiratory therapy, neonatology, or pediatrics to delivery room
- closely monitor FHR for signs of fetal distress

Clinical Features of Chorioamnionitis
- Temperature
- Tachycardia (maternal or fetal)
- Tenderness (uterine)
- Foul discharge

Clinical Features of Meconium
- Temperature
- Tachycardia (maternal or fetal)
- Tenderness (uterine)
- Foul discharge

Particulate (thickened) meconium is associated with lower APGARs, an increased risk of meconium aspiration, and perinatal death. Particulate meconium generally has a darker green or black colour, whereas thin meconium is usually yellow to light green.
Operative Obstetrics

Operative Vaginal Delivery

Definition
• forceps or vacuum extraction

Indications
• fetal
  • atypical or abnormal fetal heart rate tracing, evidence of fetal compromise
  • consider if second stage is prolonged, as this may be due to poor contractions or failure of fetal head to rotate
• maternal
  • need to avoid voluntary expulsive effort (e.g. cardiac/cerebrovascular disease)
  • exhaustion, lack of cooperation, and excessive analgesia may impair pushing effort

Contraindications
• non-vertex cephalic presentation (i.e. brow or face)
• unengaged head
• cervix incompletely dilated

Forceps

Outlet Forceps Position
• head visible between labia in between contractions
• sagittal suture in or close to AP diameter
• rotation cannot exceed 45°

Low Forceps Position
• presenting part at station +2 or greater
• subdivided based on whether rotation less than or greater than 45 degrees

Mid Forceps Position
• presenting part below spines but above station +2

Types of Forceps
• Simpson or Tucker-McLane forceps for OA presentations
• Kielland (rotational) forceps when rotation of head is required
• Piper forceps for breech

Vacuum Extraction

• traction instrument used as alternative to forceps delivery; aids maternal pushing
• contraindications: <34 wk GA (<2500 g), fetal head deflexed, fetus requires rotation, fetal condition (e.g. bleeding disorder)

| Table 23. Advantages and Disadvantages of Forceps versus Vacuum Extraction |
|---------------------------------|---------------------------------|
| **Forces** | **Vacuum Extraction** |
| Advantages | Higher overall success rate for vaginal delivery |
| | Decreased incidence of fetal morbidity |
| | Easier to apply |
| | Less anesthesia required |
| | Less maternal soft-tissue injury compared to forceps |
| Disadvantages | Greater incidence of maternal injury |
| | Contraindicated if fetus at risk for coagulation defect |
| | Suitable only for vertex presentations |
| | Maternal pushing required |
| | Contraindicated in preterm delivery |

Complications
• Maternal: anesthesia risk, lacerations, injury to bladder, uterus, or bone, pelvic nerve damage, PPH, infections
• Fetal: fractures, facial nerve palsy, trauma to face/scalp, intracerebral hemorrhage, cephalohematoma, cord compression
• Increased incidence of cephalohematoma and retinal hemorrhages, and jaundice compared to forceps
• Subgaleal hemorrhage
• Subaponeurotic hemorrhage
• Soft tissue trauma

Limits for Trial of Vacuum
• After 3 pulls over 3 contractions with no progress
• After 3 pop-offs with no obvious cause
• 20 min and delivery is not imminent
Lacerations

- first degree: involves skin and vaginal mucosa but not underlying fascia and muscle
- second degree: involves fascia and muscles of the perineal body but not the anal sphincter
- third degree: involves the anal sphincter (partial IIIa or complete IIIb)
- fourth degree: extends through the anal sphincter into the rectal mucosa

Episiotomy

Definition
- incision in the perineal body at the time of delivery
- essentially a controlled second degree laceration
- midline: incision through central tendinous portion of perineal body and insertions of superficial transverse perineal and bulbocavernous muscle
- mediolateral: incision through bulbocavernous, superficial transverse perineal muscle, and levator ani

Indications
- to relieve obstruction of the unyielding perineum
- to expedite delivery (e.g. abnormal FHR pattern)
- instrumental delivery
- controversial between practitioners as to whether it is preferable to make a cut or let the perineum tear as needed
- current evidence suggests letting perineum tear and then repair as needed (restricted use)

Complications
- infection, hematoma, extension into anal musculature or rectal mucosa, fistula formation, incontinence

Cesarean Delivery

Epidemiology
- incidence 20-25%

Indications
- maternal: obstruction, active herpetic lesion on vulva, invasive cervical cancer, previous uterine surgery (past C/S is most common), underlying maternal illness (eclampsia, HELLP syndrome, heart disease) maternal-fetal: failure to progress, placental abruption or previa, vasa previa
- fetal: abnormal fetal heart tracing, malpresentation, cord prolapse, certain congenital anomalies

Types of Cesarean Incisions
- skin
  - transverse (i.e. Pfannenstiel)
    - decreased exposure and slower entry
    - improved strength and cosmesis
  - vertical midline
    - rapid peritoneal entry and increased exposure
    - increased dehiscence
- uterine
  - low transverse (most common): in noncontractile lower segment
    - decreased chance for rupture in subsequent pregnancies
  - low vertical
  - used for very preterm infants, poorly developed maternal lower uterine segment
  - classical (rare): in thick, contractile segment
    - used for transverse lie, preterm b ee, fetal anomaly, >2 fetuses, lower segment adhesions, obstructing fibroid, morbidly obese patients

Risks/Complications
- complications related to general anesthesia* (e.g. aspiration)
- hemorrhage (average blood loss ~1,000 cc)
- infection (UTI, wound, endometritis)
  - single dose prophylactic antibiotic should be used (e.g. cefazolin 1-2 g)
- injury to surrounding structures (bowel, bladder, ureter, uterus)
- thromboembolism (DVT, PE)
- increased recovery time/hospital stay
- maternal mortality (<0.1%)
**Trial of Labour after Cesarean Section (TOLAC)**

- should be recommended if no contraindications after previous low transverse incision
- success rate varies with indication for previous C/S (generally 60-80%)
- risk of uterine rupture (<1% with low transverse incision), increased by interval <18 months and one layer closure

**Contraindications**
- previous classical, inverted T, or unknown uterine incision, or complete transection of uterus (6% risk of rupture)
- history of uterine surgery (e.g. myomectomy) or previous uterine rupture
- multiple gestation
- non-vertex presentation or placenta previa
- inadequate facilities or personnel for emergency C/S

---

**Puerperal Complications**

- puerperium: 6 wk period of adjustment after pregnancy when pregnancy-induced anatomic and physiologic changes are reversed

---

**Postpartum Hemorrhage**

**Definition**
- loss of >500 mL of blood at the time of vaginal delivery, or >1,000 mL with C/S
- early (immediate) – within first 24 h postpartum
- late (delayed) – after 24 h but within first 6 wk

**Epidemiology**
- incidence 5-15%

**Etiology (4 Ts)**

1. **Tone** (uterine atony)
   - most common cause of PPH
   - avoid by giving oxytocin with delivery of the anterior shoulder or placenta occurs within first 24 h
   - due to:
     - overdistended uterus (polyhydramnios, multiple gestations, macrosomia)
     - uterine muscle exhaustion (prolonged or rapid labour, grand multiparity, oxytocin use, general anesthetic)
     - uterine distortion (fibroids, placenta previa, placental abruption)
     - intra-amniotic infection (fever, prolonged ROM)

2. **Tissue**
   - retained placental products (membranes, cotyledon or succenturiate lobe)
   - retained blood clots in an atonic uterus
   - gestational trophoblastic neoplasia
   - abnormal placentation

3. **Trauma**
   - laceration (vagina, cervix, uterus), episiotomy, hematoma (vaginal, vulvar, retroperitoneal), uterine rupture, uterine inversion

4. **Thrombin**
   - coagulopathy (pre-existing or acquired)
   - most identified prior to delivery (low platelets increases risk)
   - includes hemophilia, DIC, Aspirin® use, ITP, TTP, vWD (most common)
   - therapeutic anti-coagulation

**Investigations**
- assess degree of blood loss and shock by clinical exam
- explore uterus and lower genital tract for evidence of tone, tissue, or trauma
- may be helpful to observe red-topped tube of blood – no clot in 7-10 min indicates coagulation problem

**Management**
- ABCs, call for help
- 2 large bore IVs, run crystalloids wide open
- CBC, coagulation profile, cross and type pRBCs
- treat underlying cause
- Foley catheter to empty bladder and monitor urine output

---

**VBAC**
- Rate of successful VBAC ranges from 60-82%
- No significant difference in maternal deaths or hysterectomies between VBAC or C/S
- Uterine rupture more common in VBAC group
- Evidence regarding fetal outcome is lacking

---

**VBAC**
- Rate of successful VBAC ranges from 60-82%
- No significant difference in maternal deaths or hysterectomies between VBAC or C/S
- Uterine rupture more common in VBAC group
- Evidence regarding fetal outcome is lacking

---

**DDx of Early PPH – 4 Ts**
- Tone (atony)
- Tissue (retained placenta, clots)
- Trauma (laceration, inversion)
- Thrombin (coagulopathy)

**DDx of Late PPH**
- Retained products
- ± endometritis
- Sub involution of uterus
**Medical Therapy**
- oxytocin 5 U IV bolus (20-40 U/250 mL crystalloid) with delivery of anterior shoulder or infusion of 20 U in 1000 mL crystalloid at 50 mL/h or can give 10 U IM if CV collapse or IV access not possible
- methylergonovine maleate (ergotamine) 0.25 mg IM/IMM q15min up to 1.25 mg; can be given as IV bolus of 0.125 mg (may exacerbate HTN)
- carbo-prost (Hemabate®), a synthetic PGF-1α analog, 250 µg IM/IMM q15min to max 2 mg (major prostaglandin side effects and contraindicated in cardiovascular, pulmonary, renal, and hepatic dysfunction)
- misoprostol 600-800 µg PO/SL (faster) or PR/PV (side effect: pyrexia if >600 µg)
- tranexamic acid (Cyklokapron®), an antifibrinolytic, 1 g IV

**Local Control**
- bimanual massage: elevate the uterus and massage through patient's abdomen
- uterine packing (mesh with antibiotic treatment)
- Bakri Balloon for tamponade: may slow hemorrhage enough to allow time for correction of coagulopathy or for preparation of an OR

**Surgical Therapy (Intractable PPH)**
- D&C (beware of vigorous scraping which can lead to Asherman's syndrome)
- embolization of uterine artery or internal iliac artery by interventional radiologist
- laparotomy with bilateral ligation of uterine artery (may be effective), internal iliac artery (not proven), ovarian artery, or hypogastric artery, compression sutures (B-Lynch or Cho sutures)
- hysterectomy last option, with angiographic embolization if post-hysterectomy bleeding

---

### Retained Placenta

**Definition**
- placenta undelivered after 30 min postpartum

**Etiology**
- placenta separated but not delivered
- abnormal placental implantation (placenta accreta, placenta increta, placenta percreta)

**Risk Factors**
- placenta previa, prior C/S, post-pregnancy curettage, prior manual placental removal, uterine infection

**Clinical Features**
- risk of postpartum hemorrhage and infection

**Investigations**
- explore uterus
- assess degree of blood loss

**Management**
- 2 large bore IVs, type and screen
- Brant maneuver (firm traction on umbilical cord with one hand applying suprapubic pressure cephalad to avoid uterine inversion by holding uterus in place)
- oxytocin 10 IU in 20 mL NS into umbilical vein
- manual removal if above fails
- D&C if required
- Ancef 2 g IV if manual removal or D&C

---

### Uterine Inversion

**Definition**
- inversion of the uterus through cervix ± vaginal introitus

**Etiology/Epidemiology**
- often iatrogenic (excess cord traction with fundal placenta)
- excessive use of uterine tocolytics
- more common in grand multiparous (lax uterine ligaments)
- 1/1,500-1/2,000 deliveries

**Clinical Features**
- can cause profound vasovagal response with bradycardia, vasodilation, and hypovolemic shock
- shock may be disproportionate to maternal blood loss

**Management**
- urgent management essential, call anesthesia
- ABCs: initiate IV crystalloids
Puerperal Complications

• can use tocolytic drug (see Management of Preterm Labour, OB16) or nitroglycerin IV to relax uterus and aid replacement
• replace uterus without removing placenta
• remove placenta manually and withdraw slowly
• IV oxytocin infusion (only after uterus replaced)
• re-explore uterus
• may require general anesthetic ± laparotomy

Postpartum Pyrexia

Definition
• fever >38°C on any 2 of the first 10 d postpartum, except the first day

Etiology
• endometritis
• wound infection (check C/S and episiotomy sites)
• mastitis/engorgement
• UTI
• atelectasis
• pneumonia
• DVT, pelvic thrombophlebitis

Investigations
• detailed history and physical exam, relevant cultures
• for endometritis: blood and genital cultures

Treatment
• depends on etiology
  • infection: empiric antibiotics, adjust when sensitivities available
    • endometritis: clindamycin + gentamycin IV
    • mastitis: clindamycin or cephalaxin
    • wound infection: cephalaxin, frequent sitz baths for episiotomy site infection
    • DVT: anticoagulants
  • prophylaxis against post-C/S endometritis: administer 2g of Cephazolin IV 30 minutes prior to skin incision

ENDOMETRITIS
• definition: infection of uterine myometrium and parametrium
• clinical features: fever, chills, abdominal pain, uterine tenderness, foul-smelling discharge, or lochia
• treatment: depends on infection severity; oral antibiotics if well, IV with hospitalization in moderate to severe cases

VENOUS THROMBOEMBOLISM
• see Venous Thromboembolism, OB30

Mastitis

• definition: inflammation of mammary glands
• must rule out inflammatory carcinoma, as indicated
• differentiate from mammary duct ectasia: mammary duct(s) beneath nipple clogged and dilated ± ductal inflammation ± nipple discharge (thick, grey to green), often postmenopausal women

Table 24 Lactational vs. Non-Lactational Mastitis

<table>
<thead>
<tr>
<th></th>
<th>Lactational</th>
<th>Non-Lactational</th>
</tr>
</thead>
<tbody>
<tr>
<td>Epidemiology</td>
<td>More common than non-lactational</td>
<td>Periductal mastitis most common</td>
</tr>
<tr>

<td></td>
<td>Purulent nipple discharge</td>
<td>Treatment includes antibiotics, aspiration, or I&amp;D (tends to recur)</td>
</tr>
<tr>
<td></td>
<td>Fever, leukocytosis</td>
<td>May develop mammary duct fistula</td>
</tr>
<tr>
<td></td>
<td>Discontinue nursing, IV antibiotics (nafcillin/oxacillin), I&amp;D usually required</td>
<td>A minority of non-lactational abscesses may occur peripherally in breast with no associated periductal mastitis (usually S. aureus)</td>
</tr>
</tbody>
</table>
Postpartum Mood Alterations

POSTPARTUM BLUES
- 40-80% of new mothers, onset day 3-10; extension of the “normal” hormonal changes and adjustment to a new baby
  - self-limited, should resolve by 2 wk
  - manifested by mood lability, depressed affect, increased sensitivity to criticism, tearfulness, fatigue, irritability, poor concentration/despondency, anxiety, insomnia

POSTPARTUM DEPRESSION
- definition: major depression occurring in a woman within 6 mo of childbirth (see Psychiatry, PS12)
- epidemiology: 10-15%, risk of recurrence 50%
- risk factors
  - personal or family history of depression (including PPD)
  - prenatal depression or anxiety
  - stressful life situation
  - poor support system
  - unwanted pregnancy
  - colicky or sick infant
- clinical features: suspect if the “blues” last beyond 2 wk, or if the symptoms in the first 2 wk are severe (e.g., extreme disinterest in the baby, suicidal or homicidal/infanticidal ideation)
  - assessment: Edinburgh Postnatal Depression Scale or other
  - treatment: antidepressants, psychotherapy, supportive care, ECT if refractory
- prognosis: interferes with bonding and attachment between mother and baby, so it can have long-term effects

POSTPARTUM PSYCHOSIS
- definition: onset of psychotic symptoms over 24-72 h within first month postpartum, can present in the context of depression
- epidemiology: rare (0.2%)

Postpartum Care

Postpartum Office Visit at 6 Weeks

Care of Mother (The 10 Bs)
- Be careful: do not use douches or tampons for 4-6 wk post-delivery
- Be fit: encourage gradual increases in walking, Kegel exercises
- Birth control: assess for use of contraceptives; breastfeeding is NOT an effective method of birth control (see Gynecology, GY17, for more detail about different contraceptive options postpartum)
- Bladder: assess for urinary incontinence, maintain high fluid intake
- Blood pressure: especially if gestational HTN
- Blood tests: CBC (for anemia if had PPH)
- Blues: (see Postpartum Mood Alterations)
- Bowel: fluids and high-fibre foods, bulk laxatives; for hemorrhoids/perineal tenderness: pain meds, doughnut cushion, Sitz baths, ice compresses
- Breast and pelvic exam: watch for Staphylococcal or Streptococcal mastitis/abscess, ± Pap smear at 6 wk

Physiological Changes Postpartum
- uterus weight rapidly diminishes through catabolism, cervix loses its elasticity and regains firmness
  - should involute ~1 cm below umbilicus per day in first 4-5 d, reaches non-pregnant state in 4-6 wk postpartum
- ovulation resumes in ~45 d for non-lactating women and within 3-6 mo for lactating women and sometimes later
- lochia: normal vaginal discharge postpartum, uterine decidual tissue sloughing
  - decreases and changes in colour from red (lochia rubra; presence of erythrocytes, 3-4 d) → pale (lochia serosa) → white/yellow (lochia alba; residual leukorrhoea) over 3-6 wk
  - foul-smelling lochia suggests endometritis

Breastfeeding Problems
- inadequate milk: consider domperidone
- breast engorgement: cool compress, manual expression/pumping
- nipple pain: clean milk off nipple after feeds, moisture cream, topical steroid if needed
- mastitis: treat promptly (see Postpartum Pyrexia, OB45)
- inverted nipples: makes feeding difficult
- maternal medications: may require pediatric consultation (see Breastfeeding and Drugs)
Bladder Dysfunction
- pelvic floor prolapse can occur after vaginal delivery
- stress or urge urinary incontinence common
- increased risk with instrumental delivery or prolonged second stage
- conservative management: pelvic floor retraining with Kegel exercises/pelvic physiotherapy, vaginal cone or pessaries, lifestyle modifications (e.g. limit fluid, caffeine intake)
- surgical management: minimally invasive procedures (tension-free vaginal tape, transobturator tape, midurethral sling)

Puerperal Pain
- "after pains" common in first 3 d due to uterine contractions; encourage simple analgesia
- ice packs can be used on perineum if painful
- encourage regular analgesia and stool softener

Figure 4. Loss of vision
Ocular Pain

- differentiate from eye fatigue (asthenopia)
- ocular surface disease
- herpes zoster prodrome
- trauma/foreign body
- blepharitis
- keratitis
- corneal abrasion/ulcer
- acute glaucoma
- acute uveitis
- scleritis
- episcleritis
- optic neuritis

Floaters

- PVD (often secondary to age-related vitreous syneresis)
- vitreous hemorrhage
- retinal tear/detachment
- intermediate uveitis (pars planitis)
- posterior uveitis (chorioretinitis)

Flashes of Light (Photopsia)

- PVD (often secondary to age-related vitreous syneresis)
- retinal tear/detachment
- migraine with aura

Photophobia (Severe Light Sensitivity)

- corneal abrasion, corneal ulcer
- keratitis
- acute angle-closure glaucoma
- iritis
- meningitis/encephalitis
- migraine
- subarachnoid hemorrhage (SAH)

Diplopia (Double Vision)

<table>
<thead>
<tr>
<th>Binocular Diplopia</th>
<th>Monocular Diplopia</th>
</tr>
</thead>
<tbody>
<tr>
<td>Occurs with both eyes open, eliminated with occlusion of either eye</td>
<td>Occurs with one eye open, remains with occlusion of unaffected eye</td>

</tbody>
</table>

Table 2 Common Causes of Diplopia

- Disease of eye muscle: congenital strabismus syndromes
- Ocular motor nerve dysfunction: III IV VI Nerve Palsy
- Neuromuscular junction disease: myasthenia gravis, botulism
- Mechanical process: muscle restriction/entrapment, thyroid ophthalmopathy
- Optical factors: refractive error/astigmatism
- Mechanical process: dislocated lens, postoperative sequelae (cataract surgery, peripheral laser iridotomy)
- Other: strands of mucus in tear film (keratoconus)

Supranuclear Causes

INO (multiple sclerosis, brainstem infarct)

Ocular Problems in the Contact Lens Wearer

- solution hypersensitivity
- tight lens syndrome
- corneal abrasion
- giant papillary conjunctivitis/contact lens allergy
- SPK from dry eyes
- limbal stem cell deficiency
- corneal neovascularization
- sterile corneal infiltrates (immunologic)
- infected ulcers (Pseudomonas, Acanthamoeba)

Acute Painless Vision Loss

- vitreous hemorrhage
- retinal artery/vein occlusion
- RD
- AION
- optic neuritis
- amaurosis fugax/TIA/stroke

Nausea and vomiting

Ocular Emergencies

These require urgent ophthalmology consultation for management

Sight Threatening
- lid/globe lacerations
- chemical burn
- corneal ulcer
- gonococcal conjunctivitis
- acute iritis
- acute glaucoma
- CRAO
- intraocular foreign body
- RD (especially when macula threatened)
- endophthalmitis
- GCA

Life-Threatening
- proptosis (rule out cavernous sinus fistula or thrombosis)
- CN III palsy with dilated pupil (intracranial aneurysm or externally compressive neoplastic lesion)
- papilledema (elevated increased intracranial pressure workup)
- orbital cellulitis
- leukocoria: white reflex (absent red reflex, must rule out retinoblastoma)

The Ocular Examination

Visual Acuity – Distance
- Snellen Acuity (Figure 5) = testing distance (usually 20 ft or 6 m)
  smallest line patient can read on the chart
- e.g. 20/40 = what the patient can see at 20 feet (numerator), what a “normal” person can see at 40 feet (denominator)
- distance visual acuity should be tested with distance glasses on in order to obtain best corrected visual acuity
- testing hierarchy for low vision: Snellen acuity (20/x) → counting fingers at a given distance (CF) → hand motion (HM) → light perception with projection (LP with projection) → light perception (LP) → no light perception (NLP)
• legal blindness is BCVA that is ≤20/200 in best eye
• minimum visual requirements to operate a non-commercial automobile in Ontario are: 20/50 BCVA with both eyes open and examined together, 120° continuous horizontal visual field, and 15° continuous visual field above and below fixation

Visual Acuity – Near
• use pocket vision chart (Rosenbaum Pocket Vision Screener)
• record Jaeger (J) or Point number and testing distance (usually 30 cm) e.g. J2 @ 30 cm
• conversion to distance visual acuity possible (e.g. immobile patient, no distance chart available)

Visual Acuity for Infants, Children, Non-English Speakers, and Dysphasics
• newborns
  • VA cannot be tested conventionally
• 3 mo-3 yr (can only assess visual function, not acuity)
• test each eye for fixation symmetry using an interesting object
• normal function noted as “CSM” = central, steady, and maintained
• 3 yr until alphabet known
• pictures or letter cards/charts such as HOTV or Sheridan-Gardner test (children point to optotypes on a provided matching card)
• tumbling “E” chart

Colour Vision
• test with Ishihara pseudoisochromatic plates
• record number of correctly identified plates presented to each eye, specify incorrect plates
• important for testing optic nerve function (e.g. optic neuritis, chloroquine use, thyroid ophthalmopathy)
• note: red-green colour blindness is sex-linked and occurs in 7-10% of males

VISUAL FIELDS
• test “visual fields by confrontation” (4 quadrants, each eye tested separately) for estimation of visual field loss
• accurate, quantifiable assessment with automated visual field testing (Humphrey or Goldmann) or Tangent Screen
• use Amsler grid (each eye tested separately) to check for central or paracentral scotomas (blindspots) in patients with AMD

PUPILS
• use reduced room illumination with patient focusing on distant, fixed object to prevent near reflex
• examine pupils for shape, size, symmetry, and reactivity to light (both direct and consensual response)
• test for RAPD with swinging flashlight test, check by reverse RAPD if one pupil non-reactive
• test pupillary constriction portion of near reflex by bringing object close to patient’s nose
• “normal” pupil testing often noted as PERRLA (pupils equal, round, reactive to light and accommodation)

ANTERIOR CHAMBER DEPTH
• shine light tangentially from temporal side
• if >2/3 of nasal side of iris in shadow → shallow anterior chamber

The van Herick Method (Slit Lamp technique)
• shine thin-angled slit beam onto the peripheral cornea of each eye, view at a 60° angle from the beam
• estimate depth between the posterior surface of the cornea and the iris as a proportion of corneal thickness
• ratios ≤1/4 implies risk of occludable angle; however, if >1/4, this does not rule out risk
• gonioscopy, as performed by an ophthalmologist, is gold-standard for assessing anterior chamber depth

EXTRAOCULAR MUSCLES
Alignment
• Hirschberg corneal reflex test
  • examine in primary position of gaze (i.e. straight ahead) with patient focusing on distant object
  • shine light into patient’s eyes from ~30 cm away
  • corneal light reflex should be at the same position on each cornea
  • strabismus testing as indicated (cover test, cover-uncover test, prism testing) (see Strabismus, OP50)

Movement
• examine movement of eyeball through six cardinal positions of gaze
• ask patient if diplopia or pain is present in any position of gaze
• observe for horizontal, vertical, or rotatory nystagmus (rhythmic, oscillating movements of the eye)
• resolving horizontal nystagmus at end-gaze is usually normal

Diplopia
• see Neurology – Neuro-ophthalmology Diplopia
SLIT-LAMP EXAMINATION

Ocular Adnexa
- lids, lashes, lacrimal system

Anterior Segment
- conjunctiva / sclera
- cornea
  - fluorescein dye: stains de-epithelialized cornea; dye appears fluorescent green with cobalt blue filtered light
  - Rose Bengal dye: stains devitalized corneal epithelium
- anterior chamber/angle (Van Herick)
- iris/pupil
- lens (assess for cataract)
- anterior vitreous

Posterior Segment (requires 78D or 90D lens)
- vitreous
- optic disc (colour, C:D ratio, sharpness of disc margin)
- macula (~1.5-2 disc diameters temporal to disc), fovea (foveal light reflex)
- retinal vessels
- retinal background

TONOMETRY
- measurement of IOP
- normal range is 9-21 mmHg (average 15 mmHg)
- IOP has diurnal variation, so always record the time of day at which the measurement was taken
- commonly measured by:
  - GAT: clinical gold standard, performed using the slit-lamp with special tip (prism)
  - Tono-Pen*: benefit is portability and use of disposable probe tips; use when cornea is scarred/ asymmetric (GAT inaccurate)
  - air puff (non-contact and least reliable)
- use topical anesthetic for GAT and Tono-Pen*; apply fluorescein dye when using GAT

DIRECT OPHTHALMOSCOPY
- best performed with pupils dilated (for list of mydriatics and cycloplegics see Table 13, OP58)
  1. assess red reflex
     - light reflected off the retina produces a "red reflex" when viewed from ~1 foot away
     - anything that interferes with the passage of light will diminish the red reflex (e.g. large vitreous hemorrhage, cataract, retinoblastoma)
  2. examine the posterior segment of the eye
     - vitreous
     - optic disc (colour, C:D ratio, sharpness of disc margin)
     - macula (~1.5-2 disc diameters temporal to disc), fovea (foveal light reflex)
     - retinal vessels
     - retinal background
     - contraindications to pupillary dilatation
     - shallow anterior chamber – can precipitate acute angle-closure glaucoma
     - iris-supported anterior chamber lens implant
     - potential neurologic abnormality requiring pupil evaluation
     - use caution with cardiovascular disease – mydriatics may cause tachycardia and hypertension

REFRACTION
- two techniques used
  - flash/streak retinoscopy: refractive error determined objectively by the examiner using lenses and retinoscope
  - manifest: subjective trial using loose lenses or a phoropter (device the patient looks through that is equipped with lenses)
    - cycloplegic: manifest refraction with accommodation temporarily paralyzed with cycloplegics
  - a typical lens prescription would contain
    - sphere power in dioptre (measurement of refractive power of lens, equal to reciprocal of focal length in metres)
    - cylinder power in dioptre to correct astigmatism
    - axis of cylinder in degrees
    - "add" (bifocal/progressive reading lens) for presbyopes
    - e.g. -1.50 + 1.00 x 120 degrees, add +2.00

Optics

Aqueous Flare
- Resembles dust particles in a beam of light
- Results from protein leaking from blood vessels
- Distinguish from aqueous cells (individual cells in anterior chamber)

Figure 8. Diagnostic positions of gaze for isolated primary actions of extraocular muscles

Figure 9. Slit-lamp examination note

Figure 10. Tonometry
REFRACTIVE EYE SURGERY
- permanently alters corneal refractive properties by ablating tissue to change curvature of the cornea
- used for correction of myopia, hyperopia, and astigmatism
- common types include PRK and LASIK
- potential risks/side-effects: infection, under/overcorrection, increased glare/halo perception at night, corneal haze (PRK only), dry eyes (more common in LASIK than PRK), regression, and flap complications such as free cap (loss of flap), traumatic flap dislocations, buttonhole flap, and epithelial in growth (LASIK only)

Table 4. Optics

<tr>
<td>Emmetropia</td>
<td>Image of distant objects focus exactly on the retina</td>
<td>No refractive error</td>
<td></td>
</tr>
<tr>
<td>Myopia</td>
<td>Globe too long relative to refractive mechanisms, or refractive mechanisms too strong</td>
<td>“Nearsightedness” Usually presents in 1st or 2nd decade, stabilizes in 2nd and 3rd decade; rarely begins after age 25 except in patients with DM or cataracts Blurring of distance vision; near vision usually unaffected Prevalence: 30-40% in U.S. population</td>
<td>Correct with negative dioptr/concave/“negative” lenses to diverge light rays Refractive eye surgery</td>
</tr>
<tr>
<td>Hyperopia</td>
<td>Globe too short relative to refractive mechanisms, or refractive mechanisms too weak</td>
<td>“Farsightedness” Youth: usually do not require glasses (still have sufficient accommodative ability to focus image on retina), but may develop accommodative esotropia (see Strabismus, OP36)</td>
<td>When symptomatic, correct with positive dioptr/convex/“plus” lenses to converge light rays Refractive eye surgery</td>
</tr>
<tr>
<td>Astigmatism</td>
<td>Light rays not refracted uniformly in all meridians due to non-spherical surface of cornea or non-spherical lens (e.g. football-shaped) Two types Regular – curvature uniformly different in meridians at right angles to each other Irregular – distorted cornea caused by injury, keratoconus (cone-shaped cornea), corneal scar, or severe dry eye Affects ~30% of population, with prevalence increasing with age Mild astigmatism unnoticeable Higher amounts of astigmatism may cause blurry vision, squinting, asthenopia, or headaches</td>
<td>Correct with cylindrical lens (if regular Try contact lens (if irregular) Refractive eye surgery</td>
<td></td>
</tr>
<tr>
<td>Presbyopia</td>
<td>Normal aging process (&gt;40 yr) Hardening/reduced deformability of lens results in decreased accommodative ability Accommodative power is 14D at age 10, diminishes to 3.5D by age 40 yr Near images cannot be focused onto the retina (focus is behind the retina as in hyperopia) If initially emmetropic, person begins to hold reading material farther away, but distance vision remains unaffected If initially myopic, person removes distance glasses to read If initially hyperopic, symptoms of presbyopia occur earlier</td>
<td>Correct with positive dioptr/convex/“plus” lenses for reading</td>
<td></td>
</tr>
<tr>
<td>Anisometropia</td>
<td>Difference in refractive errors between eyes</td>
<td>Second most common cause of amblyopia in children</td>

</table>

Treatment
- systemic antibiotics (suspect H. influenzae in children; S. aureus or Streptococcus in adults)
  - e.g. amoxicillin-clavulanic acid
  - if severe or child <1 yr, treat as orbital cellulitis

Orbital Cellulitis

- OCULAR and MEDICAL EMERGENCY
- inflammation of orbital contents posterior to orbital septum
  - common in children, elderly, and immunocompromised

Etiology
- usually secondary to sinus/facial/tooth infections or trauma, can also arise from preseptal cellulitis

Clinical Features (see Table 6)

Treatment
- admit, blood cultures x2, orbital CT, IV antibiotics (ceftriaxone + vancomycin) for 1 wk
- surgical drainage of abscess with close follow-up, especially in children

Complications
- optic nerve inflammation, cavernous sinus thrombosis, meningitis, brain abscess with possible loss of vision, and death
Lacrical Apparatus

- tear film made up of three layers
  - outer oily layer (reduces evaporation): secreted by the Meibomian glands
  - middle watery layer (forms the bulk of the tear film): constant secretion from conjunctival glands and reflex secretion by lacrimal gland with ocular irritation or emotion
  - inner mucinous layer (aids with tear adherence to cornea): secreted by conjunctival goblet cells
- tears drain from the eyes through the upper and lower lacrimal puncta → superior and inferior canaliculi → lacrimal sac → nasolacrinal duct → nasal cavity behind inferior concha (Figure 3)

Dry Eye Syndrome (Keratoconjunctivitis Sicca)

Etiology
- aqueous-deficient
  - Sjögren syndrome (autoimmune etiology e.g. RA, SLE)
  - non-Sjögren syndrome (idiopathic age-related disease; lacrimal gland scarring e.g. trachoma; decreased secretion e.g. contact lenses, CN VII palsy, anticholinergics, antihistamines, diuretics, β blockers)
- evaporative (normal lacrimal function, excessive evaporation of aqueous layer)
  - Meibomian gland dysfunction (posterior blepharitis)
  - vitamin A deficiency (xerophthalmia with goblet cell dysgenesis)
  - eyelid abnormalities e.g. ectropion, CN VII palsy (decreased blinking)
  - topical ocular medications with preservatives
  - contact lenses, allergic conjunctivitis
- mixed etiologies are common

Clinical Features
- dry eyes, red eyes, foreign body sensation, blurred vision, tearing
- slit-lamp exam: decreased tear meniscus, decreased tear break-up time (normally should be 10 s), punctate staining of cornea with fluorescein

Investigations
- surface damage observed with fluorescein/Rose Bengal staining
- decreased distance in Schirmer's test

Complications
- erosions and scarring of cornea

Treatment
- medical: preservative-free artificial tears up to q1h and ointment at bedtime (preservative toxicity becomes significant if used more than 4-6x/day), short course of mild topical corticosteroid, omega-3 fatty acids orally, and eyelid hygiene for blepharitis
  - for moderate cases, cyclosporine ophthalmic emulsion 0.05% (Restasis®) can be used
- procedural: punctal occlusion (punctal plug insertion), lid taping, tarsorrhaphy (sew lids together) if severe
- treat underlying cause

Epiphora (Excessive Tearing)

Etiology
- emotion, pain
- environmental stressor (cold, wind, pollen, sleep deprivation)
- lid/lash malposition: ectropion, entropion, trichiasis
- inflammatory: conjunctivitis, dacryoadenitis, uveitis, keratitis, corneal foreign body
- dry eyes (reflex tearing)
- lacrimal drainage obstruction (congenital failure of canalization, aging, rhinitis, dacryocystitis)
- paradoxical gustatory lacrimation reflex (crocodile tears)

Investigations
- using fluorescein dye, examine for punctal reflux by pressing on canaliculi
- Jones dye test: fluorescein placed in conjunctival cul-de-sac, and cotton applicator placed in nose to detect flow (i.e. rule out lacrimal drainage obstruction)

Treatment
- lid repair for ectropion or entropion
- eyelash removal for trichiasis
- punctal irrigation (dilation and irrigation)
- nasolacrimal duct probing (infants)
- tube placement: temporary (Crawford) or permanent (Jones)
- surgical: dacryocystorhinostomy – forming a new connection between the lacrimal sac and the nasal cavity

Long-term use of artificial tears with preservatives should be avoided when treating dry eyes
Excessive tearing can be caused by dry eyes – if the tear quality is insufficient, “reflex tearing” may occur
Dacryocystitis

• acute or chronic infection of the lacrimal sac
• most commonly due to obstruction of the nasolacrimal duct
• commonly associated with *S. aureus, S. pneumoniae, Pseudomonas* species

Clinical Features

• pain, swelling, redness over lacrimal sac at medial canthus
• epiphora, crusting, ± fever
• digital pressure on the lacrimal sac may extrude pus through the punctum
• in the chronic form, epiphora may be the only symptom

Treatment

• warm compresses, nasal decongestants, systemic and topical antibiotics
• if chronic, obtain cultures by aspiration
• once infection resolves, consider dacryocystorhinostomy

Dacryoadenitis

• inflammation of the lacrimal gland (outer third of upper eyelid)
• acute causes: *S. aureus, mumps, EBV, herpes zoster, N. gonorrhoeae*
• chronic causes (often bilateral): lymphoma, leukemia, sarcoidosis, tuberculosis, thyroid ophthalmopathy

Clinical Features

• pain, swelling, tearing, discharge, redness of the outer region of the upper eyelid
• chronic form is more common and may present as painless enlargement of the lacrimal gland

Treatment

• supportive: warm compresses, oral NSAIDs
• systemic antibiotics if bacterial cause
• if chronic, treat underlying disorder

Lids and Lashes

Lid Swelling

Etiology

• commonly due to allergy, with shriveling of skin between episodes
• dependent edema on awakening (e.g. CHF, renal or hepatic failure)
• orbital venous congestion due to mass or cavernous sinus fistula
• dermatochalasis (loose skin due to aging or heredity)
• lid cellulitis, thyroid disease (e.g. myxedema), trauma, chemosis

Ptosis

• drooping of upper eyelid

Etiology

• aponeurotic: disinsertion or dehiscence of levator aponeurosis (most common)
  • associated with advancing age, trauma, surgery, pregnancy, chronic lid swelling
• mechanical
  • incomplete opening of eyelid due to mass or scarring
• neuromuscular
  • myasthenia gravis (neuromuscular palsy), myotonic dystrophy
  • CN III palsy
  • Horner’s syndrome (see *Constricted Pupil, Horner’s Syndrome, OP30*)
• congenital
• pseudoptosis (e.g. dermatochalasis, enophthalmos, contralateral exophthalmos)
• drugs (e.g. high dose opioids, heroin abuse, pregabalin)

Treatment

• surgery (e.g. blepharoplasty, levator resection, Müller’s muscle resection, frontalis sling)
**Trichiasis**

- eyelashes turned inwards
- may result from entropion, involutional age change, chronic inflammatory lid diseases (e.g. blepharitis), trauma, burns
- patient complains of red eye, foreign body sensation, significant discomfort, tearing
- may result in corneal ulceration and scarring

**Treatment**

- topical lubrication, repeat eyelash epilation, electrolysis, cryotherapy

**Entropion**

- lid margin turns in towards globe causing tearing, foreign body sensation, and red eye
- most commonly affects lower lid
- may cause corneal abrasions with secondary corneal scarring

**Etiology**

- involutonal (aging)
- cicatricial (herpes zoster, surgery, trauma, burns)
- orbicularis oculi muscle spasm
- congenital

**Treatment**

- lubricants, evert lid with tape, surgery

**Ectropion**

- lid margin turns outward from globe causing tearing and possibly exposure keratitis

**Etiology**

- involutonal (aging)
- paralytic (CN VII palsy)
- cicatricial (burns, trauma, surgery)
- mechanical (lid edema, tumour, herniated fat)
- congenital

**Treatment**

- topical lubrication, eyelid taping overnight, surgery

**Hordeolum (Stye)**

- acute inflammation of eyelid gland: either Meibomian glands (internal lid), glands of Zeis (modified sweat gland) or Moll (modified sebaceous gland in external lid)
- infectious agent is usually *S. aureus*
- painful, red swelling of lid

**Treatment**

- warm compresses, lid care, gentle massage
- topical antibiotics are typically ineffective
- usually resolves within 2 wk, but may require incision and drainage

**Chalazion**

- chronic granulomatous inflammation of Meibomian gland often preceded by an internal hordeolum
- acute inflammatory signs are usually absent
- differential diagnosis: basal cell carcinoma, sebaceous cell adenoma, Meibomian gland carcinoma

**Treatment**

- warm compresses
- if no improvement after 1 mo, consider incision and curettage
- chronic recurrent lesion must be biopsied to rule out malignancy

Testing for Entropion

Forced lid closure: Ask patient to tighten lid then open. In entropion, lid rolls inwards

Testing for Ectropion

Snapback test: Pull eyelid inferiorly. In ectropion, lid remains away from globe

Hordeolum vs. Chalazion

Hordeolums are due to an infectious etiology, whereas chalazions are granulomatous inflammation
Blepharitis

- inflammation of lid margins

**Etiology**
- Anterior blepharitis
  - staphylococcal (S. aureus): ulcerative, dry scales
  - seborrheic: no ulcers, greasy scales
- Posterior blepharitis
  - Meibomian gland dysfunction

**Clinical Features**
- itching, tearing, foreign body sensation
- thickened, red lid margins, crusting, discharge with pressure on lids (“toothpaste sign”)

**Complications**
- recurrent hordeola
- conjunctivitis
- keratitis (from poor tear film)
- corneal ulceration and neovascularization

**Treatment**
- warm compresses, lid massages, and lid washing using commercially available eyelid scrub solution
- topical or systemic antibiotics as needed
- if severe, ophthalmologist may prescribe a short course of topical corticosteroids, omega-3 fatty acids

Xanthelasma

- eyelid xanthoma (lipid deposits in dermis of lids)
- appear as pale, slightly elevated yellowish plaques or streaks
- most commonly on the medial upper lids, often bilateral
- associated with hyperlipidemia (~50% of patients)
- common in the elderly, more concerning in the young

**Treatment**
- excision for cosmesis only, commonly recurs

Conjunctiva

thin, vascular mucous membrane
- bulbar conjunctiva: lines sclera to limbus (junction between cornea and sclera)
- palpebral (tarsal) conjunctiva: lines inner surface of eyelid

Pinguecula

- yellow-white subepithelial deposit of hyaline and elastic tissue adjacent to the nasal or temporal limbus, sparing the cornea
- associated with sun and wind exposure, aging
- benign, sometimes enlarges slowly
- may be irritating due to abnormal tear film formation over the deposits
- surgery for cosmesis only
- irritative symptoms may be treated with lubricating drops

Pterygium

- fibrovascular, triangular, wing-like encroachment of epithelial tissue onto the cornea
- may induce astigmatism, decrease vision
- excision for chronic inflammation, threat to visual axis, cosmesis
- irritative symptoms may be treated with lubricating drops
- one-third recur after excision, lower recurrence with conjunctival autograft (~5%)

Subconjunctival Hemorrhage

- blood beneath the conjunctiva, otherwise asymptomatic
- idiopathic or associated with trauma, Valsalva maneuver, bleeding disorders, HTN, anticoagulation
- give reassurance if no other ocular findings, resolves spontaneously in 2-3 wk
- 360 degree involvement should be highly suspicious for globe rupture if trauma history
- if recurrent, consider medical/hematologic workup
Conjunctivitis

Etiology
- infectious
  - bacterial, viral, chlamydial, gonococcal, fungal, parasitic
- non-infectious
  - allergic, atopic, seasonal, giant papillary conjunctivitis (contact lens wearers)
  - toxic: irritants, dust, smoke, irradiation
  - secondary to another disorder: dacryocystitis, dacyroadenitis, cellulitis, systemic inflammatory disease

Clinical Features
- red eye (conjunctival injection often with limbal pallor), chemosis, corneal subepithelial infiltrates
- itching, foreign body sensation, tearing, discharge, crusting of lashes in the morning, lid edema
- ± preauricular and/or submandibular nodes
- follicles: pale lymphoid elevations of the conjunctiva, overlain by vessels
- papillae: fibrovascular elevations of the conjunctiva with central network of finely branching vessels (cobblestone appearance)

ALLERGIC CONJUNCTIVITIS
- associated with rhinitis, asthma, dermatitis, hay fever
- ocular pruritus, small papillae, chemosis, redness, thickened and erythematous lids
- seasonal (pollen, grasses, plant allergens)

Treatment
- allergen avoidance, cool compresses, non-preserved artificial tears, topical or oral antihistamine, topical mast cell stabilizer (e.g. cromolyn, ketotifen, olopatadine), topical corticosteroids

Atopic Conjunctivitis
- onset late adolescence and early adulthood with peak between 30-50 years old
- intense ocular pruritus (perennially), tearing, burning, clear mucus discharge, redness, blurry vision, photophobia, and foreign body sensation
- thickened and intermittent swelling of the eyelids, conjunctival chemosis, conjunctival hyperemia, and tarsal papillary hypertrophy

Treatment
- calcineurin inhibitor ointment (e.g. tacrolimus and pimecrolimus), and topical corticosteroid (clobetasone)

Giant Papillary Conjunctivitis
- immune reaction to mucus debris on lenses in contact lens wearers
- large papillae form on superior palpebral conjunctiva

Treatment
- clean, change or discontinue use of contact lens, topical corticosteroids

Vernal Conjunctivitis
- large papillae (cobblestones) form on superior palpebral conjunctiva with corneal ulcers and keratitis
- seasonal (warm weather)
- occurs in children, lasts for 5-10 yr then resolves

Treatment
- non-preserved artificial tears, consider topical steroid, topical cyclosporine (by ophthalmologist)

VIRAL CONJUNCTIVITIS (pink eye)
- presents with itchiness, pain and swelling
- serous discharge, lid edema, follicles, pseudomembranes
- subepithelial corneal infiltrates
- preauricular node often palpable and tender
- initially unilateral, often progresses to the other eye within a few days
- mainly due to adenovirus – highly contagious for up to 12 d

Treatment
- cool compresses, topical lubrication.
- usually self-limiting (7-12 d)
- proper hygiene is important to prevent transmission

BACTERIAL CONJUNCTIVITIS
- purulent discharge, lid swelling, papillae, conjunctival injection, chemosis
- common agents include S. aureus, S. pneumoniae, H. influenzae and M. catarrhalis
- in neonates or if sexually active must consider N. gonorrhoeae (invades cornea to cause keratitis)
- C. trachomatis is the most common cause in neonates

Treatment
- topical broad-spectrum antibiotic, systemic antibiotics if indicated (especially in neonates and children)
- usually a self-limited course of 10-14 d if no treatment, 1-3 d with treatment
OP15 Ophthalmology

GONOCOCCAL AND CHLAMYDIAL CONJUNCTIVITIS
- caused by N. gonorrhoeae and C. trachomatis, respectively
- affects sexually active individuals, neonates (ophthalmia neonatorum) in first 5 d of life when caused by gonorrhea (shorter incubation period) and d 3-14 of life when caused by chlamydia (longer incubation period)
- newborn prophylaxis with 0.5% erythromycin ointment no longer recommended
- chlamydia causes trachoma and inclusion conjunctivitis (different serotypes)

Trachoma
- leading infectious cause of blindness in the world
- severe keratoconjunctivitis leads to corneal abrasion, ulceration, and scarring
- initially, follicles on superior palpebral conjunctiva and later palpebral scarring (Arlt’s line)

Treatment
- oral azithromycin and topical tetracycline

Inclusion Conjunctivitis
- chronic conjunctivitis with follicles and subepithelial infiltrates
- most common cause of conjunctivitis in newborns
- newborn prophylaxis with 0.5% erythromycin ointment no longer recommended

Treatment
- oral azithromycin, tetracycline, doxycycline

Sclera
- white fibrous outer protective coat of the eye, composed of irregularly distributed collagen bundles
- continuous with the cornea anteriorly and the dura of the optic nerve posteriorly
- episclera is a thin layer of vascularized tissue between the sclera and conjunctiva

Episcleritis
- immunologically mediated inflammation of episclera
- 1/3 bilateral; simple (80%) or nodular (20%)
- more frequent in women than men (3:1)

Etiology
- mostly idiopathic
- associated with collagen vascular diseases, infections (herpes zoster, herpes simplex, syphilis), inflammatory bowel disease, rosacea, atopy

Clinical Features
- may have discomfort and pain associated with red eye (often interpalpebral)
- sectoral or diffuse injection of radially-directed vessels, chemosis, small mobile nodules
- blanches with topical phenylephrine (constricts superficial vessels)

Treatment
- generally self-limited, recurrent in 2/3 of cases
- topical steroid (prescribed and monitored by ophthalmologist)
- oral NSAID

Scleritis
- usually unilateral: can be classified as anterior or posterior and diffuse, nodular, necrotizing with inflammation, or necrotizing without inflammation (scleromalacia perforans)
- anterior scleritis: pain radiating to face, may cause scleral thinning, in some cases necrotizing
- posterior scleritis: rapidly progressive blindness, may cause exudative RD
- more common in women and elderly

Etiology
- may be a manifestation of systemic disease
- collagen vascular disease, e.g. SLE, RA, GCP, ankylosing spondylitis
- granulomatous, e.g. tuberculosis, sarcoidosis, syphilis
- metabolic, e.g. goit, thyrotoxicosis
- infectious, e.g. S. aureus, S. pneumoniae, P. aeruginosa, herpes zoster
- chemical or physical agents, e.g. thermal, alkali, or acid burns
- idiopathic

Clinical Features
- severe “deep” or “boring” pain, photophobia, red eye, decreased vision
- pain is 1 st indicator of disease progression
- inflammation of scleral, episcleral, and conjunctival vessels

To differentiate between episcleritis and scleritis, place a drop of phenylephrine 2.5% (Mydristine®; Alcon) in the affected eye. Re-examine the vascular pattern 10-15 min later; if episcleritis the episcleral vessels should blanch with phenylephrine.

Scleromalacia Perforans
- Asymptomatic anterior necrotizing scleritis without inflammation
- Strongly associated with RA
- May result in scleral thinning
- Traumatic perforation can easily occur – examine eye very gently

Preventing Ophthalmia Neonatorum
Paediatr Child Health 2015;20(2):93-96
The use of silver nitrate as prophylaxis for neonatal ophthalmia was instituted in the late 1800s to prevent the devastating effects of neonatal ocular infection with Neisseria gonorrhoeae. At that time – during the preantibiotic era – many countries made such prophylaxis mandatory by law. Today, neonatal gonococcal ophthalmia is rare in Canada, but ocular prophylaxis for this condition remains mandatory in some provinces/territories. Silver nitrate drops are no longer available and erythromycin, the only ophthalmic antibiotic eye ointment currently available for use in newborns, is of questionable efficacy. Ocular prophylaxis is not effective in preventing chlamydial conjunctivitis. Applying medication to the eyes of newborns may result in mild eye irritation and has been perceived by some parents as interfering with mother-infant bonding. Physicians caring for newborns should advocate for rescinding mandatory ocular prophylaxis laws. More effective means of preventing ophthalmia neonatorum include screening all pregnant women for gonorrhea and chlamydia infection, and treatment and follow-up of those found to be infected. Mothers who were not screened should be tested at delivery. Infants of mothers with untreated gonococcal infection at delivery should receive ceftriaxone. Infants exposed to chlamydia at delivery should be followed closely for signs of infection.
• may have anterior chamber cells and flare, corneal infiltrate, scleral thinning, scleral edema
• sclera may have a purple or “violaceous” hue (best seen in natural light), due to rearranged scleral fibres
• failure to blanch with topical phenylephrine

**Treatment**
• vision threatening – needs to be referred to ophthalmology
• life threatening- indicator of poor systemic disease control with an increased 5 year mortality rate (not from scleritis) without treatment of underlying untreated or unrecognized autoimmune condition
• systemic NSAID, systemic steroid, and systemic immunomodulation
• treat underlying etiology

---

**Cornea**

• function
  ■ transmission of light
  ■ refraction of light (2/3 of total refractive power of eye)
  ■ barrier against infection, foreign bodies
  ■ transparency due to avascularity, uniform collagen structure and deturgescence (relative dehydration)
  ■ 5 layers (anterior to posterior): epithelium, Bowman's layer, stroma, Descemet's membrane, and the endothelium (dehydrates the cornea; dysfunction leads to corneal edema). Some have argued the existence of a 6th layer, “Du’s layer”, although it is debated if this is a truly unique and additional layer. extensive sensory fibre network (V1 distribution) therefore abrasions are very painful

---

**Foreign Body**

• foreign material in or on cornea
• may have associated rust ring if metallic
• patients may note pain, tearing, photophobia, foreign body sensation, red eye
• signs include foreign body, conjunctival injection, epithelial defect that stains with fluorescein, corneal edema, anterior chamber cells/flare

**Complications**
• abrasion, infection, ulcer, scarring, rust ring, secondary iritis

**Treatment**
• remove under magnification using local anesthetic and sterile needle or refer to ophthalmology for removal under magnification (depending on depth and location)
• treat as per cornea abrasion

---

**Corneal Abrasion**

• epithelial defect usually due to trauma (e.g. fingernails, paper, twigs), contact lens (Figure 14)

**Clinical Features (Table 7)**
• pain, redness, tearing, photophobia, foreign body sensation
• de-epithelialized area stains with fluorescein dye
• pain relieved with topical anesthetic (DO NOT use for treatment- risk of corneal melt or infection)

**Complications**
• infection, ulceration, recurrent erosion, secondary iritis

**Treatment**
• topical antibiotic (drops or ointment), abrasion from organic material should be covered against pseudomonas
• consider topical NSAID (caution due to risk of corneal melt with prolonged use), cycloplegic (relieves pain and photophobia by paralyzing ciliary muscle), patch
• most abrasions clear spontaneously within 24-48 h

---

**Recurrent Erosions**

• recurrent episodes of pain, photophobia, foreign body sensation with a spontaneous corneal epithelial defect
• usually occurs upon awakening
• associated with improper adherence of epithelial cells to the underlying basement membrane

**Etiology**
• previous traumatic corneal abrasion
• corneal dystrophy
• idiopathic
Treatment
• same as corneal abrasion until re-epithelialization occurs
• topical hypertonic saline ointment at bedtime for 6-12 mo, topical lubrication
• bandage contact lens, anterior stromal puncture or photo therapeutic keratectomy for chronic recurrences

Corneal Ulcer

Etiology
• local necrosis of corneal tissue due to infection
  • infection is usually bacterial; rarely viral, fungal, or protozoan (Acanthamoeba)
  • secondary to corneal exposure, abrasion, foreign body, contact lens use (50% of ulcers)
  • also associated with conjunctivitis, blepharitis, keratitis, vitamin A deficiency

Clinical Features
• pain, photophobia, tearing, foreign body sensation, decreased VA (if central ulcer)
• corneal opacity that necroses and forms an excavated ulcer with infiltrative base
• overlying corneal epithelial defect that stains with fluorescein
• may develop corneal edema, conjunctival injection, anterior chamber cells/flare, hypopyon, corneal hypoesthesia (in viral keratitis)
• bacterial ulcers may have purulent discharge, viral ulcers may have watery discharge

Complications
• decreased vision, corneal perforation, iritis, endophthalmitis

Investigations
• Seidel test: fluorescein drop on the cornea under cobalt blue filter is used to detect leaking penetrating lesions; any aqueous leakage will dilute the green stain at site of wound

Treatment
• urgent referral to ophthalmology
• culture prior to treatment
• topical antibiotics every hour
• must treat vigorously to avoid complications

Herpes Simplex Keratitis

• usually HSV type 1 (90% of population are carriers)
• may be triggered by stress, fever, sun exposure, immunosuppression

Clinical Features
• pain, tearing, foreign body sensation, red eye, may have decreased vision, eyelid edema
• corneal hypoesthesia
• classic form of HSV infectious epithelial keratitis is a dendritic (thin and branching) lesion with terminal end bulbs in epithelium that stains with fluorescein
• HSV may cause other forms of infectious epithelial keratitis, as well as stromal keratitis (which may be infectious or immune-mediated), and endotheliitis (presumably immune-mediated but possible role of live virus)

Complications
• corneal scarring (can lead to loss of vision)
• chronic interstitial keratitis due to penetration of virus into stroma
• secondary iritis, secondary glaucoma

Treatment
• topical antiviral such as trifluridine, or systemic antiviral such as acyclovir
• debridement of dendrite
• NO STEROIDS initially – may exacerbate condition
• ophthalmologist must exercise caution if adding topical steroids for stromal keratitis, endotheliitis or iritis, and patients covered with antiviral prophylaxis
Herpes Zoster Ophthalmicus

- dermatitis in the dermatomal distribution of CN V1 that is typically unilateral and respects the midline
- Hutchinson's sign: if tip of nose is involved (nasociliary branch of V1) then globe will be involved in ~75% of cases
  if no nasal involvement, eye is involved in 1/3 of patients

Clinical Features
- pain, tearing, photophobia, red eye
- corneal edema, pseudodendritis, SPK
- corneal hypoesthesia

Complications
- keratitis, ulceration, perforation and scarring
- secondary iritis, secondary glaucoma, cataract
- muscle palsies (rare) due to CNS involvement
- occasionally severe post-herpetic neuralgia

Treatment
- oral antiviral (acyclovir, valcyclovir, or famciclovir) immediately
- topical steroids, cycloplegia as indicated for immune-mediated keratitis, iritis
- erythromycin ointment if conjunctival involvement

Keratoconus

- bilateral thinning and bulging (ectasia) of the cornea resulting in a conical shape
- usually sporadic but can be associated with Down's syndrome, atopy, contact lens use and vigorous eye rubbing
- associated with breaks in Descemet's membrane and Bowman's layer
- results in decreased vision from irregular astigmatism, scarring and stromal edema

Treatment
- attempt correction with spectacles and/or rigid gas permeable contact lens
- corneal collagen cross-linking treatment to halt disease progression
- intrastromal corneal ring segments can help flatten the corneal cone
- penetrating keratoplasty or deep anterior lamellar keratoplasty (partial-thickness corneal transplant) as last resort

Arcus Senilis

- hazy white ring in peripheral cornea, <2 mm wide, clearly separated from limbus
- common, bilateral, benign corneal degeneration due to lipid deposition, part of the aging process
- may be associated with hypercholesterolemia if age <40 yr, check lipid profile
- no associated visual symptoms, complications or treatment necessary

Kayser-Fleischer Ring

- brown-yellow-green pigmented ring in peripheral cornea, starting inferiorly
- due to deposition of copper pigment in Descemet's membrane
- associated with Wilson's disease
- no associated symptoms or complications of ring
- treat underlying disease
The Uveal Tract

- uveal tract (from anterior to posterior) = iris, ciliary body, choroid
- vascularized, pigmented middle layer of the eye, between the sclera and the retina

Uveitis

- uveal inflammation which may involve one, two, or all three parts of the tract
- idiopathic or associated with autoimmune, infectious, granulomatous, malignant causes
- should be managed by an optometrist or ophthalmologist
- anatomically classified as anterior uveitis, intermediate uveitis, posterior uveitis, or panuveitis based on primary site of inflammation

Table 8. Anatomic Classification of Uveitis

<table>
<thead>
<tr>
<th>Location</th>
<th>Anterior Uveitis (Iritis)</th>
<th>Intermediate Uveitis</th>
<th>Posterior Uveitis</th>
</tr>
</thead>
<tbody>
<tr>
<td>Location</td>
<td>Inflammation of iris, usually accompanied by cyclitis (inflammation of ciliary body), both = iridocyclitis</td>
<td>The vitreous is the major site of the inflammation</td>
<td>Inflammation of the choroid and/or retina</td>
</tr>
<tr>
<td>Etiology</td>
<td>Usually idiopathic</td>
<td>Mostly idiopathic, secondary causes include sarcoidosis, Lyme disease, and multiple sclerosis</td>
<td>Bacterial: syphilis, tuberculosis</td>
</tr>
<tr>
<td>Infectious: syphilis, Lyme disease, toxoplasmosis, TB, HSV, herpes zoster</td>
<td></td>
<td></td>
<td>Fungal: histoplasmosis, candidiasis</td>
</tr>
<tr>
<td>Other: sarcoidosis, trauma, large abrasion, post ocular surgery</td>
<td></td>
<td></td>
<td>Parasitic: toxoplasmosis (most common cause) toxocara</td>
</tr>
<tr>
<td>Clinical Features</td>
<td>Photophobia (due to reactive spasm of inflamed iris (ciliary muscle spasm), decreased VA, lacrimation Ciliary flush (perilimbal conjunctival injection), miosis (spasm of sphincter muscle)</td>
<td>Insidious onset of blurred vision, accompanied by vitreous floaters Initial symptoms are usually unilateral but inflammatory changes are usually bilateral and asymmetric</td>
<td>Painless as choroid has no sensory innervation</td>
</tr>
<tr>
<td>Anterior chamber &quot;cells&quot; (WBC in anterior chamber due to anterior segment inflammation) and &quot;flare&quot; (protein precipitates in anterior chamber secondary to inflammation), hypopyon (collection of neutrophilic exudates inferiorly in the anterior chamber)</td>
<td></td>
<td>Associated with anterior uveitis, most severe cases of secondary intermediate uveitis</td>
<td>Often no conjunctival or scleral injection present</td>
</tr>
<tr>
<td>Occasionally keratic precipitates (clumps of cells on corneal endothelium) Iritis typically reduces IOP because ciliary body inflammation causes decreased aqueous production; however, severe iritis or iritis from herpetic encephalitis and zoster may cause an inflammatory glaucoma (trabectitis)</td>
<td></td>
<td>Vitreous cells, condensations, and snowballs (vitreous aggregates of inflammatory cells) Posterior segment 'snowbank' = grey-white fibrovascular plaque at the pars plana</td>
<td>Decreased VA</td>
</tr>
<tr>
<td>Complications</td>
<td>Inflammatory glaucoma Posterior synechiae Adhesions of posterior iris to anterior lens capsule Indicated by an irregularly shaped pupil If occurs 360°, can lead to angle closure glaucoma Peripheral anterior synechiae (rare): adhesions of iris to cornea → secondary angle closure glaucoma Cataracts Band keratopathy (with chronic iritis) Superficial corneal calcification keratopathy Macular edema with chronic iritis</td>
<td>Cystoid macular edema (30% of cases), cataract, and glaucoma</td>
<td>Macular edema Vitriris Neovascularization Visual field loss/scotoma</td>
</tr>
<tr>
<td>Treatment</td>
<td>Mydriatics: dilate pupil to prevent formation of posterior synechiae and to decrease pain from ciliary spasm Steroids: topical, sub-tenon, or systemic Systemic analgesia If recurrent episodes, extensive medical workup may be indicated to rule out secondary causes</td>
<td>Systemic or sub-tenon/intravitreal steroids and immunosuppressive agents Vitrectomy, cryotherapy, or laser photoagulation to the &quot;snowbank&quot;</td>
<td>Steroids: sub-tenon, intravitreal, or systemic if indicated (e.g. threat of vision loss)</td>
</tr>
</tbody>
</table>
Lens

• consists of an outer capsule surrounding a soft cortex and a firm inner nucleus

Cataracts

• any opacity of the lens, regardless of etiology
• most common cause of reversible blindness worldwide
• types: nuclear sclerosis, cortical, posterior subcapsular

Etiology

• acquired
  • age-related (over 90% of all cataracts)
  • cataract associated with systemic disease (may have juvenile onset)
    • DM
    • meabolic disorders (e.g. Wilson's disease, galactosemia, homocystinuria)
    • hypocalcemia
  • traumatic (may be rosette shaped)
  • intraocular inflammation (e.g. uveitis)
  • toxic (steroids, phenothiazines)
  • radiation
• congenital
  • high myopia
  • present with altered red reflex or leukocoria
  • treat promptly to prevent amblyopia

Clinical Features

• gradual, painless, progressive decrease in VA
• glare, dimness, halos around lights at night, monocular diplopia
• "second sight" phenomenon: patient is more myopic than previously noted, due to increased refractive power of the lens in nuclear sclerosis only
  • patient may read without previously needed reading glasses
• diagnosis by slit-lamp exam
• may impair view of retina during fundoscopy

Treatment

• medical: no role for medical management
• surgical: definitive treatment
  • indications for surgery
    • to improve visual function in patients whose vision loss leads to functional impairment
    • to aid management of other ocular disease (e.g. cataract that prevents adequate retinal exam or laser treatment of DR)
    • congenital or traumatic cataracts
  • phacoemulsification (phaco = lens)
  • most commonly used surgical technique
  • post-operative complications: RD, endophthalmitis, dislocated IOL, macular edema, glaucoma, posterior capsular opacification

Dislocated Lens (Ectopia Lentis)

Etiology

• associated with Marfan's Syndrome, Ehlers-Danlos type VI, homocystinuria, syphilis, lens coloboma (congenital cleft due to failure of ocular adnexa to complete growth)
• traumatic

Clinical Features

• decreased VA
• may get monocular diplopia
• iridodonesis (quivering of iris with movement)
• phacodonesis (observed movement of the lens)
• direct ophthalmoscopy may elicit abnormal red reflex

Complications

• cataract, glaucoma, uveitis

Treatment

• surgical lens replacement
**Vitreous**

- clear gel (99% water plus collagen fibrils, glycosaminoglycans, and hyaluronic acid) that fills the posterior segment of eye
- normally adherent to optic disc, pars plana, and along major retinal blood vessels

**Posterior Vitreous Detachment**

**Etiology**
- central vitreous commonly shrinks and liquefies with age (syneresis)
- during syneresis, molecules that hold water condense causing vitreous floaters
- liquid vitreous moves between posterior vitreous gel and retina
- vitreous is peeled away and separates from the internal limiting membrane of the neurosensory retina posterior to the vitreous base

**Clinical Features**
- floaters, flashes of light

**Complications**
- traction at sites of firm adhesion may result in a retinal tear with or without subsequent rhegmatogenous retinal detachment
- retinal tears/detachment may cause vitreous hemorrhage if bridging retinal blood vessel is torn
- complications more common in high myopes and following ocular trauma (blunt or perforating)

**Treatment**
- acute onset of PVD requires a dilated fundus exam to rule out retinal tears/detachment
- no specific treatment available for floaters/flashes of light

**Vitreous Hemorrhage**

- bleeding into the vitreous cavity

**Etiology**
- PDR
- retinal tear/detachment
- PVD
- retinal vein occlusion
- trauma

**Clinical Features**
- sudden loss of VA
- may be preceded by “shower” of many floaters and/or flashes of light
- ophthalmoscopy: no red reflex if large hemorrhage, retina not visible due to blood in vitreous

**Treatment**
- ultrasound (B-scan) to rule out RD
- expectant: in non-urgent cases (e.g. no RD), blood usually resorbs in 3-6 mo
- surgical: vitrectomy ± RD repair ± retinal endolaser to possible bleeding sites/vessels

**Endophthalmitis and Vitritis**

- intraocular infection: acute, subacute, or chronic

**Etiology**
- most commonly a post-operative complication; risk following cataract surgery is <0.1%
- also due to penetrating injury to eye (risk is 3-7%), endogenous spread, and intravitreal injections
- etiology usually bacterial, may be fungal

**Clinical Features**
- painful, red eye, photophobia, discharge
- severely reduced VA, lid edema, proptosis, corneal edema, anterior chamber cells/flare, hypopyon, reduced red reflex
- may have signs of a ruptured globe (severe subconjunctival hemorrhage, hyphema, decreased IOP, etc.)

**Treatment** *(see Ocular Trauma, OP39)*
- OCULAR EMERGENCY: presenting vision best indicates prognosis
- LP or worse: admission, immediate vitrectomy, and intravitreal antibiotics to prevent loss of vision
- HM or better: vitreous tap for culture and intravitreal antibiotics
- topical fortified antibiotics

**Weiss Ring**: formed by glial tissue around the optic disc that remains attached to the detached posterior vitreous

**Floaters**: “bugs”, “cobwebs”, or “spots” of vitreous condensation that move with eye position

**Although most floaters are benign, new or markedly increased floaters or flashes of light require a dilated fundus exam to rule out retinal tears/detachment**

**Any time a vitreous or retinal hemorrhage is seen in a child, must rule out child abuse**

Remember to inquire about tetanus status in post-traumatic endophthalmitis
Retina

- composed of two parts (Figure 2)
  - neurosensory retina: comprises 9 of the 10 retinal layers, including the photoreceptors and the ganglion cell layer
  - retinal pigment epithelium (RPE) layer: external to neurosensory retina
- macula: rich in cones (for colour vision); most sensitive area of retina
- fovea: centre of macula; responsible for detail, fine vision, lacks retinal vessels
- optic disc: collection of retinal nerve fibre layers forming optic nerve (CN2)
- ora serrata: irregularly-shaped, anterior margin of the retina (cannot be visualized with direct ophthalmoscope)

Central/Branch Retinal Artery Occlusion

Etiology
- occlusion of blood flow from following causes results in loss of vision due to oxygen starvation of the retinal tissues and eventual cell death
  - emboli from carotid arteries or heart (e.g. arrhythmia, endocarditis, valvular disease)
  - thrombus
  - temporal arteritis

Clinical Features
- sudden, painless (except in GCA), severe monocular loss of vision
- RAPD
- patient may have experienced transient episodes in the past (amaurosis fugax)

fundoscopy
- “cherry-red spot”
- retinal pallor
- cotton wool spots (retinal infarcts)
- cholesterol emboli (Hollenhorst plaques) – usually located at arteriole bifurcations

Treatment
- OCULAR EMERGENCY: attempt to restore blood flow within 2 h (irreversible retinal damage if >90 min of complete CRAO)
- massage the globe (compress eye with heel of hand for 10 s, release for 10 s, repeat for 5 min) to dislodge embolus
- decrease IOP
  - topical β-blockers
  - IV acetazolamide
  - IV mannitol (draws fluid from eye)
  - drain aqueous fluid – anterior chamber paracentesis (carries risk of infection, lens puncture)
- Nd:YAG laser embololysis
- intra-arterial or intra-venous thrombolysis

Central/Branch Retinal Vein Occlusion

- second most frequent “vascular” retinal disorder after DR
- usually a manifestation of a systemic disease (e.g. HTN, DM)
- thrombus occurs within the lumen of the central retinal vein/arteriovenous crossing point

Predisposing Factors
- arteriosclerotic vascular disease
- HTN
- DM
- glaucoma
- hyperviscosity (e.g. polycythemia rubra vera, sickle-cell disease, lymphoma, leukemia)
- drugs (e.g. oral contraceptive pill, diuretics)

Clinical Features
- painless, monocular, gradual or sudden vision loss
- ± RAPD
- fundoscopy
  - “blood and thunder” appearance
  - diffuse retinal hemorrhages, cotton wool spots, venous engorgement, swollen optic disc, macular edema
- two fairly distinct groups
  - venous stasis/non-ischemic retinopathy
    - no RAPD, VA ~ 20/80
    - mild hemorrhage, few cotton wool spots
    - resolves spontaneously over weeks to months
    - may regain normal vision if macula intact
  - ischemic retinopathy
    - RAPD, VA < 20/200
    - dark or orange macula
    - severe vision loss
    - may have retinal neovascularization

Intravitreal Aflibercept injection for Macular Edema Resulting from Central Retinal Vein Occlusion: One Year results of Phase 3 GAULIEO study
Ophthalmology 2014; 121(1) 202-8
Treatment with intravitreal aflibercept provided significant functional and anatomic benefits after 52 weeks as compared with sham. The improvement achieved after 6 monthly doses at week 24 were maintained until week 52 with prn dosing.
Retina

Complications
- neovascularization of retina and iris (secondary rubeosis), leading to secondary glaucoma
- vitreous hemorrhage
- macular edema

Treatment
- treatment available for complications of CRVO/BRVO, including retinal laser photoacoagulation, anti-VEGF and/or corticosteroid injection

Retinal Detachment
- cleavage in the plane between the neurosensory retina and the RPE
  - three types
    - rhegmatogenous (most common)
      - caused by a tear or hole in the neurosensory retina, allowing fluid from the vitreous to pass into the subretinal space
    - tractional
      - caused by vitreal, epiretinal, or subretinal membrane pulling the neurosensory retina away from the underlying RPE
    - exudative
      - caused by damage to the RPE resulting in fluid accumulation in the subretinal space
      - main causes are intraocular tumours, posterior uveitis, central serous retinopathy

Clinical Features
- sudden onset
- flashes of light
  - due to mechanical stimulation of the retinal photoreceptors
- floaters
- hazy spots in the line of vision which move with eye position due to drops of blood from torn vessels bleeding into the vitreous
- curtain of blackness/peripheral field loss
  - darkness in one field of vision when the retina detaches in that area
- loss of central vision (if macula “off”)
- decreased IOP (usually 4-5 mmHg lower than the other, normal eye)
- ophthalmoscopy: detached retina is grey-white with surface blood vessels, loss of red reflex
- ± RAPD

Treatment
- prophylactic: symptomatic tear (flashes or floaters) can be sealed off with laser/cryotherapy
  - therapeutic
    - rhegmatogenous
      - scleral buckle procedure
    - pneumatic retinopexy
    - vitrectomy plus injection of gas (injection of silicone oil in cases of recurrent detachment)
    - tractional
      - vitrectomy ± membrane removal/scleral buckling/injection of intraocular gas or silicone oil as necessary
    - exudative
    - management is nonsurgical; any underlying disease should be treated if possible

Complications
- loss of vision, vitreous hemorrhage, recurrent RD
- a RD is an emergency, especially if the macula is still attached (macula “on”)
- prognosis for visual recovery varies inversely with the amount of time the retina is detached and whether the macula is attached or not

Retinitis Pigmentosa
- hereditary degenerative disease of the retina manifested by rod > cone photoreceptor degeneration and retinal atrophy
- many forms of inheritance, most commonly autosomal recessive (60%)
Clinical Features
- night blindness, decreased peripheral vision ("tunnel vision"), decreased central vision (macular changes), glare (from posterior subcapsular cataracts; common)

Investigations
- fundoscopy: areas of “bone-spicule” pigment clumping in mid-periphery of retina, narrowed retinal arterioles, pale optic disc
electrophysiological tests: electroretinography (ERG) and electrooculography (EOG) assist in diagnosis

Treatment
- no treatments available to reverse the condition; cataract extraction improves visual function; vitamin A and vitamin E supplementation can reduce progression of disease in some patients

Age-Related Macular Degeneration
- leading cause of irreversible blindness in the Western world, associated with increasing age, usually bilateral but asymmetric

Classification
- Non-Exudative/“Dry” (Non-Neovascular) AMD
  - most common type of AMD (90% of cases)
  - slowly progressive loss of visual function
  - drusen: yellow-white deposits between the RPE and Bruch’s membrane (area separating inner choroidal vessels from RPE)
  - geographic RPE atrophy: coalescence of depigmented RPE, clumps of focal hyperpigmentation or hypopigmentation
  - may progress to neovascular AMD

- Exudative/“Wet” (Neovascular) AMD
  - 10% of AMD, but 80% of AMD that results in severe vision loss
  - choroidal neovascularization: drusen predisposes to breaks in Bruch’s membrane, causing subsequent growth and proliferation of new, fine choroidal vessels
  - may lead to: serous detachment of overlying RPE and retina, hemorrhage and lipid precipitates into the subretinal space
  - can also lead to an elevated subretinal mass due to fibrous metaplasia of hemorrhagic RD, causing disciform scarring and severe central vision loss

Risk Factors
- female
- increasing age
- family history
- smoking
- Caucasian race
- blue irides

Clinical Features
- variable degree of progressive central vision loss
- metamorphopsia (distorted vision characterized by straight parallel lines appearing convergent or wavy) due to macular edema

Investigations
- Amsler grid: held at normal reading distance with glasses on, assesses macular function
- fluorescein angiography: assess type and location of choroidal neovascularization – pathologic new vessels leak dye
- OCT retinal imaging

Treatment
- non-neovascular “dry” AMD
  - monitor, Amsler grid allows patients to check for metamorphopsia
  - low vision aids (e.g. magnifiers, closed circuit television)
  - anti-oxidants, green leafy vegetables
  - sunglasses/visor
- see Age-related Eye Disease Study 2 (AREDS2) in sidebar

- neovascular “wet” AMD
  - see Common Medications, OP42
  - intravitreal injection of anti-VEGF
    - pegaptanib (Macugen®), ranibizumab (Lucentis®), bevacizumab (Avastin®), aflibercept (Eylea®)
    - see VEGF Inhibitors, OP43
  - laser photocoagulation for neovascularization
  - no definitive treatment for disciform scarring
  - photodynamic therapy with verteporfin (Visudyne®)
    - IV injection of verteporfin, followed by low intensity laser to area of choroidal neovascularization
  - see Age-related Eye Disease Study 2 (AREDS2)
    - The original AREDS formulation contains vitamin C, E and beta-carotene, zinc and copper; reduced risk of progression to advanced AMD by 2%. Addition of lutein + zeaxanthin, DHA+EP, or both to the AREDS formulation in primary analyses didn’t reduce risk of progression to advanced AMD. However, because of the potential increased incidence of lung cancer in former smokers, lutein + zeaxanthin could be an appropriate carotenoid substitute in the AREDS formulation.
**Glaucoma**

**Definition**
- progressive, pressure-sensitive, optic neuropathy involving characteristic structural changes to optic nerve head with associated visual field changes
- commonly associated with high IOP, but not required for diagnosis

**Background**
- aqueous is produced by the ciliary body and drains into the episcleral veins via the trabecular meshwork and the Canal of Schlemm
- an isolated increase in IOP is termed ocular hypertension (OHT) - should be followed for increased risk of developing glaucoma
- pressures > 21 mmHg increase the risk of developing glaucoma
- loss of peripheral vision most commonly precedes central vision loss
- structural changes commonly precede functional changes

**Investigations**
- VA testing
- slit-lamp exam to assess anterior chamber depth; gonioscopy lens to assess angle patency
- ophthalmoscopy to assess the disc features
- tonometry to measure IOP
- visual field testing
- pachymetry to measure corneal thickness
- follow-up includes optic disc examination, IOP measurement, and visual field testing to monitor course of disease

---

**Figure 18. Glaucomatous damage**

- Pallor and cupping of optic disc (C:D ratio 0.2-0.3)
- Concentric enlargement (C:D ratio 0.5)
- Superior expansion
- Advanced/total cupping

**Figure 19. Aqueous flow and sites of potential resistance**

- Average IOP = 15 ± 3 mmHg
- Normal C:D ≤ 0.4
- Suspect glaucoma if C:D ratio > 0.6, C:D ratio differs between eyes by > 0.2, or cup approaches disc margin
**Primary Open-Angle Glaucoma**

- most common form, >95% of all glaucoma cases
- within the trabecular meshwork and the Canal of Schlemm
- insidious and asymptomatic, screening is critical for early detection

**Major Risk Factors**
- ocular hypertension (IOP >21 mmHg)
- age: prevalence at 40 yr is 1-2% and at 80 yr is 10%
- ethnicity: African descent
- familial (2-3x increased risk); polygenic
- thin central cornea (OHTS trial)

**Minor Risk Factors**
- myopia
- HTN
- DM
- hyperthyroidism (Graves’ disease)
- chronic topical ophthalmic steroid use in steroid responders – yearly eye exams recommended if >4 wk of steroid use
- previous ocular trauma
- anemia/hemodynamic crisis (ask about blood transfusions in past)

**Clinical Features**
- asymptomatic initially
- insidious, painless, gradual rise in IOP due to restriction of aqueous outflow
- bilateral, but usually asymmetric
- earliest signs are optic disc changes
  - increased C:D ratio (vertical C:D >0.6)
  - significant C:D asymmetry between eyes (>0.2 difference)
  - thinning, notching of the neuroretinal rim
  - flame shaped disc hemorrhage
  - 360° of peripapillary atrophy
  - nerve fibre layer defect
  - large vessels become nasally displaced
- visual field loss
- slow, progressive, irreversible loss of peripheral vision
- paracentral defects, arcuate scotoma, and nasal step are characteristics (Figure 19)
- late loss of central vision if untreated

**Treatment**
- medical treatment: decrease IOP by increasing the drainage and/or decreasing the production of aqueous (see Glaucoma Medications, Table 14, OP42)
  - increase aqueous outflow
    - topical cholinergics
    - topical prostaglandin analogues
    - topical α-adrenergics
  - decrease aqueous production
    - topical β-blockers
    - topical and oral carbonic anhydrase inhibitor
    - topical α-adrenergics
  - laser trabeculoplasty, cyclophotocoagulation in order to achieve selective destruction of ciliary body (for refractory cases)
  - trabeculectomy: creation of a new outflow tract from anterior chamber to under conjunctiva forming a bleb
  - minimally invasive glaucoma surgery (MIGS): implantation of IOP lowering drainage devices (e.g. iStent) through an ab interno microincisional approach
  - serial optic nerve head examinations, IOP measurements, and visual field testing to monitor disease course

**Normal Tension Glaucoma**

- POAG with IOP in normal range
- often found in women >60 yr, but may occur earlier
- associated with migraines, peripheral vasospasm, systemic nocturnal hypotension, sleep apnea
- damage to optic nerve may be due to vascular insufficiency

**Treatment**
- treat reversible causes
Secondary Open Angle Glaucoma

- increased IOP secondary to ocular/systemic disorders that obstruct the trabecular meshwork
  - steroid-induced glaucoma
  - traumatic glaucoma
  - pigmentary dispersion syndrome
  - pseudoexfoliation syndrome

Primary Angle-Closure Glaucoma

- 5% of all glaucoma cases
- peripheral iris bows forward obstructing aqueous access to the trabecular meshwork
- sudden forward shift of the lens-iris diaphragm causes pupillary block and results in impaired drainage, leading to a sudden rise in IOP

Risk Factors
- hyperopia: small eye, big lens – large lens crowds the angle
- age >70 yr
- female
- family history
- more common in people of Asian and Inuit descent
- mature cataracts
- shallow anterior chamber
- pupil dilation (topical and systemic anticholinergics, stress, darkness)

Clinical Features
- red, painful eye = RED FLAG
- unilateral, but other eye at increased risk
- decreased visual acuity, vision acutely blurred from corneal edema
- halos around lights
- nausea and vomiting, abdominal pain
- fixed, mid-dilated pupil
- marked increase in IOP; may be noticeable even to palpation (>40 mmHg)
- shallow anterior chamber ± cells in anterior chamber

Complications
- irreversible loss of vision within hours to days if untreated
- permanent peripheral anterior synechiae, resulting in permanent angle closure

Treatment
- OCULAR EMERGENCY: refer to ophthalmologist for acute angle closure glaucoma
  - aqueous suppressants and hyperosmotic agents
  - medical treatment (see Glaucoma Medications, Table 14, OP42)
    - miotic drops (pilocarpine) to reverse pupillary block
    - multiple topical IOP-lowering agents
    - hyperosmotic agents such as oral glycerine, or IV mannitol
  - laser iridotomy is definitive

Secondary Angle-Closure Glaucoma

Uveitis
- inflamed iris adheses to lens (posterior synechiae)

Neovascular Glaucoma
- abnormal blood vessels develop on surface of iris (rubeosis iridis), in the angle, and within the trabecular meshwork
- due to retinal ischemia associated with PDR or CRVO
- treatment with laser therapy to retina reduces neovascular stimulus to iris and angle vessels
Pupils

• pupil size is determined by the balance between the sphincter muscle and the dilator muscle
• sphincter muscle is innervated by the parasympathetic nervous system carried by CN III
• dilator muscle is innervated by the sympathetic nervous system (SNS)
  ■ first order neuron = hypothalamus → brainstem → spinal cord
  ■ second order/preganglionic neuron = spinal cord → sympathetic trunk via internal carotid artery → superior cervical ganglion in neck
  ■ third order/postganglionic fibres originate in the superior cervical ganglion, neurotransmitter is norepinephrine
    ◆ as a diagnostic test, 4-10% cocaine prevents the re-uptake of norepinephrine, and will cause dilation of normal pupil, but not one with loss of sympathetic innervation (Horner's Syndrome)
• see Neurology, Figure 8 N8

Pupillary Light Reflex

• light shone directly into eye travels along optic nerve (CN II, afferent limb) → optic tracts → bilateral midbrain
• impulses enter bilaterally in midbrain via prepectal area and Edinger-Westphal nuclei
• nerve impulses then travel down CN III (efferent limb) bilaterally to reach the ciliary ganglia, and finally to the iris sphincter muscle, which results in the direct and consensual light reflexes

α1 – Pupillary dilator muscle contraction (Mydriasis)
β2 – Ciliary muscle relaxation (Non-accommodation); increased aqueous humour production
M3 – Pupillary sphincter contraction (Miosis); increased ciliary muscle contraction (Accommodation)

Denervation Hypersensitivity

• when post-ganglionic fibres are damaged, the understimulated end-organs attempts to compensate by developing an excess of neuroreceptors and becomes hypersensitive
• postganglionic parasympathetic lesions (i.e. Adie’s pupil)
  ■ pupil will constrict with 0.125% pilocarpine (cholinergic agonist), normal pupil will not
• postganglionic sympathetic lesions (this test is used to differentiate between pre- and post-ganglionic lesions in Horner’s syndrome)
  ■ pupil will dilate with 0.125% epinephrine, normal pupil will not

Local Disorders of Iris

• posterior synechiae (adhesions between iris and lens) due to iritis can present as an abnormally shaped pupil
• ischemic damage (e.g. post-acute angle-closure glaucoma) usually occurs at 3 and 9 o’clock positions resulting in a vertically oval pupil that reacts poorly to light
• trauma (e.g. post-intraocular surgery)

Anisocoria

• unequal pupil size
• idiopathic/physiologic anisocoria
  ■ 20% of population
  ■ round, regular, <1 mm difference
  ■ pupils reactive to light and accommodation
  ■ responds normally to mydriatics/miotics
• post eye surgery
• see Table 9 for other causes of anisocoria
Patient with Anisocoria

Relevant history and examination with specific attention to:
- History of ocular trauma
- Check old photographs (ptosis, ocular deviation, long standing anisocoria)
- Use of topical medications
- Exposure to toxins and drugs
- Associated ocular and neurologic symptoms/signs

Which pupil is abnormal?
Examine pupils in light and dark

Anisocoria accentuated by darkness (small pupil abnormal)
- Dilation lag
- Pupil:
  - Small pupil does not dilate
  - Horner's syndrome

Anisocoria equal in light and dark
- Brisk reaction to light
  - Both pupils dilate symmetrically
  - Adie's tonic pupil
  - Physiologic anisocoria

Anisocoria accentuated by light (large pupil is abnormal)
- Sluggish to light
- Light near dissociation
  - Large pupil:
    - Constricts
    - Minimal/no constriction
  - Large pupil does not constrict
  - Use of 0.1% pilocarpine
  - Adie's tonic pupil
  - Pharmacologic anisocoria

Isolated
- Ptosis/Ophthalmoplegia
- Pupil:
  - Large pupil does not constrict
  - Use of 0.1% pilocarpine

Physiologic anisocoria
- Patient:
  - Use of 0.1% pilocarpine
  - Minimal/no constriction

Patient Must Fixate on Distant Target

</tbody>
</table>
**Dilated Pupil (Mydriasis)**

**Sympathetic Stimulation**
- fight or flight response
- mydriatic drugs: epinephrine, dipivefrin (Propine®), phenylephrine

**Parasympathetic Understimulation**
- cycloplegics/mydriatics: atropine, tropicamide, cyclopentolate (parasympatholytic)
- CN III palsy
  - eye deviated down and out with ptosis present
  - etiology includes stroke, neoplasm, aneurysm, acute rise in ICP, DM (may spare pupil), trauma
  - both mydriatics and CN III palsy cause pupil dilation; however, pupils in CN III palsy will constrict briskly to pilocarpine, while pupils dilated from mydriatics will not

**Acute Angle-Closure Glaucoma**
- fixed, mid-dilated pupil

**Adie’s Tonic Pupil**
- 80% unilateral, F>M
- pupil is tonic or reacts poorly to light (both direct and consensual) but constricts with accommodation
- caused by benign lesion in ciliary ganglion; results in denervation hypersensitivity of parasympathetically innervated constrictor muscle
- dilute (0.125%) solution of pilocarpine will constrict tonic pupil but have no effect on normal pupil
- long-standing Adie's pupils are smaller than unaffected eye

**Trauma**
- damage to iris sphincter from blunt or penetrating trauma
- iris transillumination defects may be apparent using ophthalmoscope or slit-lamp
- pupil may be dilated (traumatic mydriasis) or irregularly shaped from tiny sphinter ruptures

**Constricted Pupil (Miosis)**

**Senile Miosis**
- decreased sympathetic stimulation with age

**Parasympathetic Stimulation**
- local or systemic medications such as:
  - cholinergic agents: pilocarpine, carbachol
  - cholinesterase inhibitor: phospholine iodide
  - opiates, barbiturates

**Horner’s Syndrome**
- lesion in sympathetic pathway
- difference in pupil size greater in dim light, due to decreased innervation of adrenergics to iris dilator muscle
- associated with ptosis, anhydrosis of ipsilateral face/neck
- application of cocaine 4-10% (blocks reuptake of norepinephrine) to eye does not result in pupil dilation (vs. physiologic anisocoria), therefore confirms diagnosis
- hydroxyamphetamine 1% (stimulates norepinephrine release) will dilate pupil if central or preganglionic lesion, not postganglionic lesion
- postganglionic lesions result in denervation hypersensitivity which will cause pupil to dilate with 0.125% epinephrine, whereas normal pupil will not
- causes: carotid or subclavian aneurysm, brainstem infarct, demyelinating disease, cervical or mediastinal tumour, Pancoast tumour, goitre, cervical lymphadenopathy, surgical sympathectomy, Lyme disease, cervical ribs, tabs dorsalis, cervical vertebral fractures

**Iritis**
- miotic pupil initially
- later, may be irregularly shaped pupil due to posterior synechiae
- later stages non-reactive to light

**Argyll-Robertson Pupil**
- both pupils irregular and <3 mm in diameter, ± ptosis
- does not respond to light stimulation
- responds to accommodation (light-near dissociation)
- suggestive of neurosyphilis or other conditions (DM, encephalitis MS, chronic alcoholism, CNS degenerative diseases)

**Other Causes**
- optic neuritis, retinal lesions
Relative Afferent Pupillary Defect

- also known as Marcus Gunn pupil
- impairment of direct pupillary response to light, caused by a lesion in visual afferent (sensory) pathway anterior to optic chiasm
- differential diagnosis: large RD, BRAO, CRAO, CRVO, advanced glaucoma, optic nerve compression, optic neuritis (most common)
- does not occur with media opacity (e.g. corneal edema, cataracts)
- pupil reacts poorly to light and better to accommodation
- test: swinging flashlight
  - if light is shone in the affected eye, direct and consensual response to light is decreased
  - if light is shone in the unaffected eye, direct and consensual response to light is normal
  - if the light is moved quickly from the unaffected eye to the affected eye, “paradoxical” dilation of both pupils occurs
  - observe red reflex, especially in patients with dark irides
- if the defect is bilateral there is no RAPD, as dilation is measured relative to the other eye

Malignancies

- uncommon site for 1° malignancies
- see Retinoblastoma, OP38

Lid Carcinoma

Etiology
- basal cell carcinoma (rodent ulcer) (90%)
  - spread via local invasion, rarely metastasizes
  - ulcerated centre, indurated base with pearly rolled edges, telangiectasia
- squamous cell carcinoma (<5%)
  - spread via local invasion, may also spread to nodes and metastasize
  - ulceration, keratosis of lesion
- sebaceous cell carcinoma (1-5%)
  - often masquerades as chronic blepharitis or recurrent chalazion
  - highly invasive, metastasizes
- Kaposi's sarcoma, malignant melanoma, Merkel cell tumour, metastatic tumour
Treatment
• incisional or excisional biopsies
• may require cryotherapy, radiotherapy, chemotherapy, immunotherapy
• surgical reconstruction

Uveal Melanoma
• most common 1° intraocular malignancy in adults
• more prevalent in Caucasians
• arise from uveal tract, 90% choroidal melanoma
• hepatic metastases predominate

Clinical Features
• classic appearance of a pigmented dome-shaped mass extending from the ciliary body or the choroid
• diagnosis necessitates expertise of an ophthalmologist/ocular oncologist

Treatment
• imaging to investigate spread
• depending on the size of the tumour, either radiotherapy, enucleation, limited surgery

Metastases
• most common intraocular malignancy in adults
• most commonly from breast and lung in adults, neuroblastoma in children
• usually infiltrate the choroid, but may also affect the optic nerve or extraocular muscles
• may present with decreased or distorted vision, irregularly shaped pupil, iritis, hyphema

Treatment
• local radiation, chemotherapy
• enucleation if blind, painful eye

Ocular Manifestations of Systemic Disease

HIV/AIDS
• up to 75% of patients with AIDS have ocular manifestations

External Ocular Signs
• Kaposi’s sarcoma
  • secondary to human herpes virus 8 (HHV-8), affects conjunctiva of lid or the globe
  • differential diagnosis: subconjunctival hemorrhage (non-clearing), hemangioma
  • multiple molluscum contagiosum
  • herpes simplex/zoster keratitis

Retina
• HIV retinopathy (most common)
  • cotton wool spots in >50% of HIV patients
  • intraretinal hemorrhage
  • CMV retinitis
  • ocular opportunistic infection developed when severely immunocompromised (CD4 count ≤50)
  • a necrotizing retinitis, with retinal hemorrhage and vasculitis, “brushfire” or “pizza pie” appearance
  • presents with scotomas (macular involvement and RD), blurred vision, and floaters
  • untreated infection will progress to other eye in 4-6 wk
  • treatment: virostatic agents (e.g. gancyclovir or foscarnet) via IV or intravitreal injection
• necrotizing retinitis
  • from herpes simplex virus, herpes zoster, toxoplasmosis
  • disseminated choroiditis
  • Pneumocystis carinii, Mycobacterium avium intracellulare, Candida

Other Systemic Infections
• herpes zoster
  • see Herpes Zoster, OP18
• candidal endophthalmitis
  • fluffy, white-yellow, superficial retinal infiltrate that may eventually result in vitritis
  • may present with inflammation of the anterior chamber
  • treatment: systemic amphotericin B, oral fluconazole
• toxoplasmosis
  - focal, grey-yellow-white, chorioretinal lesions with surrounding vasculitis and vitreous infiltration (vitreous cells)
  - can be congenital (transplacental) or acquired (caused by Toxoplasma gondii protozoa transmitted through raw meat and cat feces)
  - congenital form more often causes visual impairment (more likely to involve the macula)
  - treatment: pyrimethamine, sulfonamide, folic acid, or clindamycin. Considering adding steroids if severe inflammation (iritis, macular or optic nerve involvement)

### Diabetes Mellitus

- most common cause of blindness in young people in North America
- loss of vision due to:
  - progressive microangiopathy leading to macular edema
  - progressive DR → neovascularization → traction → RD and vitreous hemorrhage
  - ruberosis iridis (neovascularization of the iris) leading to neovascular glaucoma (poor prognosis)
  - macular ischemia

### Diabetic Retinopathy

#### Background
- altered vascular permeability (loss of pericytes, breakdown of blood-retinal barrier, thickening of basement membrane)
- predisposition to retinal vessel obstruction (CRAO, CRVO, and BRVO)

#### Classification
- non-proliferative: increased vascular permeability and retinal ischemia
  - microaneurysms
  - dot and blot hemorrhages
  - hard exudates (lipid deposits), non-specific for DR
  - macular edema
- advanced non-proliferative (or pre-proliferative)
  - non-proliferative findings plus:
    - venous beading (in ≥2 of 4 retinal quadrants)
    - intraretinal microvascular anomalies (IRMA) in 1 or 2 retinal quadrants
      - IRMA: dilated, leaky vessels within the retina
    - cotton wool spots (nerve fibre layer infarcts)
- proliferative
  - 5% of patients with DM will reach this stage
  - neovascularization of iris, disc, retina
  - neovascularization of iris (ruberosis iridis) can lead to neovascular glaucoma
  - vitreous hemorrhage, bleeding from fragile new vessels, fibrous tissue can contract causing tractional RD
  - may remain asymptomatic well beyond stage of optimal treatment
  - high risk of severe vision loss secondary to vitreous hemorrhage, RD

#### Screening Guidelines for Diabetic Retinopathy
- type 1 DM
  - screen for retinopathy beginning annually 5 yr after disease onset
  - annual screening indicated for all patients over 12 yr and/or entering puberty
- type 2 DM
  - initial examination at time of diagnosis, then annually
- pregnancy
  - ocular exam in 1st trimester, close follow-up throughout as pregnancy can exacerbate DR
  - gestational diabetics are not at risk for DR

#### Treatment
- Diabetic Control and Complications Trial (DCCT)
  - tight control of blood sugar decreases frequency and severity of microvascular complications
  - blood pressure control
  - focal laser for clinically significant macular edema
  - intravitreal injection of corticosteroid or anti-VEGF for fovea-involved diabetic macular edema
  - pan-retinal laser photocoagulation for PDR: reduces neovascularization, hence reducing the angiogenic stimulus from ischemic retina by decreasing retinal metabolic demand → reduces risk of blindness
  - vitrectomy for non-clearing vitreous hemorrhage and tractional RD in PDR
  - vitrectomy before vitreous hemorrhage does not improve the visual prognosis

#### Lens Changes
- earlier onset of senile nuclear sclerotic and cortical cataracts
- may get hyperglycemic cataract due to sorbitol accumulation (rare)
- changes in blood glucose levels (poor control) can suddenly cause refractive changes by 3-4 diopters
Extraocular Muscle Palsy
- usually CN III infarct
- pupil usually spared in diabetic CN III palsy, but ptosis is observed
- may involve CN IV and VI
- usually recover within few months

Optic Neuropathy
visual acuity loss due to infarction of optic disc/nerve

Optic Neuropathy
visual acuity loss due to infarction of optic disc/nerve

Hypertension
retinopathy is the most common ocular manifestation
- acute HTN retinopathy: retinal arteriolar spasm, superficial retinal hemorrhage, cotton wool spots, optic disc edema
- chronic HTN retinopathy: arteriovenous (AV) nicking, flame/blot retinal hemorrhages, microaneurysms, cotton wool spots
- increases risk of a number of other ocular diseases (DR, BRVO, CRAO/BRAO)

Multiple Sclerosis
- see Neurology N52

Clinical Features
- blurred vision and decreased colour vision: secondary to optic neuritis
- central scotoma: due to damage to papillomacular bundle of retinal nerve fibres
- diplopia: secondary to INO
- RAPD, ptosis, nystagmus, uveitis, optic atrophy, optic neuritis
- white matter demyelinating lesions of optic nerve on MRI

Treatment
- IV steroids with taper to oral form for optic neuritis
  - DO NOT treat with oral steroids in isolation, as this increases likelihood of eventual development of MS

Corticosteroids for Treating Optic Neuritis
Cochrane Database Syst Rev 2015;8:CD001430
Summary: no conclusive evidence of benefit in terms of recovery to normal visual acuity, visual field, or contrast sensitivity six months after infusion of IV or oral corticosteroids.
Results: after review of 6 RCTs evaluating systemic corticosteroids for treatment of acute optic neuritis, all meta-analyses show similar outcomes for placebo vs. corticosteroid group for visual acuity, contrast sensitivity, and visual field.
TIA/Amaurosis Fugax

- sudden, transient blindness from intermittent vascular compromise
- ipsilateral carotid most frequent embolic source
- typically monocular, lasting <5-10 min
- Hollenhorst plaques (glistening microemboli seen at branch points of retinal arterioles)

Graves’ Disease

- ophthalmopathy occurs despite control of thyroid gland status
- ocular manifestations occur secondary to sympathetic overdrive and/or specific inflammatory infiltrate of the orbital tissue

Clinical

- initial inflammatory phase is followed by a quiescent cicatricial phase

Treatment

- treat hyperthyroidism
- monitor for corneal exposure and maintain corneal hydration
- manage diplopia, proptosis, and compressive optic neuropathy with one or a combination of:
  - steroids (during acute phase)
  - orbital bony decompression
  - external beam radiation of the orbit
- consider strabismus and/or eyelid surgical procedures once acute phase subsides

Connective Tissue Disorders

- RA, juvenile idiopathic arthritis, SLE, Sjögren’s syndrome, ankylosing spondylitis, polyarteritis nodosa
- most common ocular manifestation: dry eyes (keratoconjunctivitis sicca)

Giant Cell Arteritis/Temporal Arteritis

- see Rheumatology, RH20

Clinical Features

- more common in women >60 yr
- abrupt monocular loss of vision, pain over the temporal artery, jaw claudication, scalp tenderness, constitutional symptoms, and past medical history of polymyalgia rheumatica
- ischemic optic atrophy
- 50% lose vision in other eye if untreated

Diagnosis

- temporal artery biopsy + increased ESR (ESR can be normal, but likely 80-100 in first hour), increased CRP
- if biopsy of one side is negative, biopsy the other side

Treatment

- high dose corticosteroid to relieve pain and prevent further ischemic episodes
- if diagnosis of GCA is suspected clinically: start treatment + perform temporal artery biopsy to confirm diagnosis within 2 wk of initial presentation (DO NOT WAIT TO TREAT)

Sarcoidosis

- granulomatous uveitis with large “mutton fat” keratitic precipitates and posterior synechiae
- complications include glaucoma, cataracts, retinal hemorrhages, peripheral retina neovascularization and dry eye
- neurosarcoidosis: optic neuropathy, oculomotor abnormalities, visual field loss

Treatment

- topical/systemic steroids and mydriatics
Pediatric Ophthalmology

Strabismus

- Ocular misalignment in one or both eyes, can be found in up to 3% of children
- Classification
  - Manifest (constant) vs. latent (hidden) alignment
  - Comitant (deviation equal in all positions of gaze, also known as nonparalytic or concomitant) vs. incomitant (deviation worse in certain positions, also known as paralytic or restrictive)
  - Described in direction of deviation relative to the fixating eye
- Distinguish from pseudostrabismus (prominent epicanthal folds, hypertelorism)
- Complications: amblyopia, cosmesis

Heterotropia

- Manifest deviation
  - Deviation not corrected by the fusion mechanism (i.e. deviation is apparent when the patient is using both eyes)

Types

- Exo (lateral deviation), eso- (medial deviation)
- Hyper- (upward deviation), hypo- (downward deviation)
- Esotropia = "crossed-eyes"; exotropia = "wall-eyed"

Tests

- Hirschberg test (corneal light reflex): positive if the light reflex on both corneas is asymmetrical
  - Light reflex lateral to central cornea indicates esodeviation; light reflex medial to central cornea indicates exodeviation
  - False positives occur if visual axis and anatomic pupillary axis of the eye are not aligned (angle κ)
- Cover test
  - The deviation can be quantified using prisms

Heterophoria

- Latent deviation
  - Deviation corrected in the binocular state by the fusion mechanism (i.e. deviation not seen when patient is focusing with both eyes)
- Hirschberg test will be normal (light reflexes symmetrical)
  - Very common – majority are asymptomatic
  - May be exacerbated or become manifest with asthenopia (eye strain, fatigue)

Tests

- Cover-uncover test
- Alternate cover test
  - Alternating the cover between both eyes reveals the total deviation, both latent and manifest
  - Maintain cover over one eye for 2-3 s before rapidly shifting to other eye

Cover tests

Esotropia

Exotropia

Cover - Uncover tests

Esophoria

Exophoria

Figure 25: Cover and cover-uncover tests for detection of tropias and phorias

### Accommodative Esotropia
- normal response to approaching object is the triad of the near reflex: convergence, accommodation, and miosis
- hyperopes must constantly accommodate – excessive accommodation can lead to esotropia in young children via over activation of the near reflex
- average age of onset is 2.5 yr
- usually reversible with correction of refractive error

### Non Accommodative Esotropia
- accounts for 50% of childhood strabismus most are idiopathic
- may be due to monocular visual impairment (e.g. cataract, corneal scarring, anisometropia, retinoblastoma) or divergence insufficiency (ocular misalignment that is greater at distance fixation than at near fixation)

### Amblyopia

**Definition**
- a neurodevelopmental visual disorder with unilateral (or less commonly, bilateral) reduction of best corrected visual acuity that cannot be attributed only and directly to the effect of a structural abnormality of the eye
- it is caused by abnormal visual experience early in life and cannot be remedied immediately by spectacle glasses alone
- in approximately half of the cases, amblyopia is secondary to strabismus (mainly esotropia). Other causes may include uncorrected refractive errors, anisometropia (asymmetric refractive errors) and concomitant structural ocular problems

**Detection**
- “Holler Test”: young child upset if good eye is covered
- quantitative visual acuity by age 3-4 yr using picture charts and/or matching game (Sheridan-Gardiner), testing each eye separately
- amblyopia treatment less successful after age 8-10 yr, but a trial should be given no matter what age
- prognosis: 90% will have good vision restored and maintained if treated <4 yr old
Etiology and Management

- **strabismus**
  - correct with glasses for accommodative esotropia
  - occlusion therapy (see below)
  - surgery; recession (weakening) – moving muscle insertion further back on the globe; or resection (strengthening) – shortening the muscle
  - botulinum toxin for single muscle weakening
  - after ocular alignment is restored (glasses, surgery, botulinum toxin), patching is frequently necessary to maintain vision until ~8 yr of age
  - there is no proven value for vision training in the treatment of strabismus or amblyopia

- **anisometropia**
  - amblyopia usually in the more hyperopic eye
  - the more emmetropic (normal refraction) eye receives a clear image, while the less emmetropic eye receives a blurred image; input from the blurred eye is cortically suppressed and visual pathway fails to develop normally
  - treat with glasses to correct refractive error
  - patching is required if visual acuity difference persists after 4-8 wk of using glasses

- **deprivation amblyopia**
  - occlusion due to ptosis, cataract, retinoblastoma, corneal opacity
  - occlusion amblyopia: prolonged patching of good eye may cause it to become amblyopic

Occlusion Therapy

- patching the good eye to force the brain to use the non-dominant eye and redevelop its vision
- atropine cycloplegic drops to impair accommodation and blur vision of the better seeing eye

Risks

- permanent loss of vision in the affected eye
- possibility of injury to “remaining” good eye
- safety glasses or polycarbonate lenses recommended if visual acuity in worse eye is <20/50
- loss of stereopsis

Leukocoria

- white reflex (red reflex is absent)
- the presence of leukocoria warrants urgent referral to an ophthalmologist

Differential Diagnosis

- cataract
- retinoblastoma
- retinal coloboma
- ROP
- persistent hyperplastic primary vitreous or persistent fetal vasculature
- Coats disease (exudative retinal telangiectasis)
- toxocariasis
- RD

Retinoblastoma

- most common primary intraocular malignancy in children
- incidence: 1/15,000; sporadic or genetic transmission; screening of siblings/offspring essential
- unilateral (2/3) or bilateral (1/3)
- malignant – direct or hematogenous spread
- diagnosis
  - often presents with leukocoria or strabismus
  - U/S or CT scan may demonstrate calcified mass (present in most cases)

Treatment

- radiotherapy, chemotherapy combined with laser, cryopexy, and/or enucleation

Retinopathy of Prematurity

- vasoproliferative retinopathy that is a major cause of blindness in the developed world

Risk Factors

- non-black race (black infants have lower risk of developing ROP)
- low gestational age, birth weight <1500 g
- high oxygen exposure after birth (iatrogenic)
Classification (ROP Staging)
- stage 1: faint demarcation line at the junction between the vascularized and avascular retina
- stage 2: elevated ridge
- stage 3: extra-retinal fibrovascular tissue extending into vitreous
- stage 4: partial RD (4A: macula “on”, 4B: macula “off”)
- stage 5: total RD
- plus (+) disease: dilation and tortuosity of retinal vessels
- threshold disease: stage 3+ in zones 1 or 2 with circumferential extent of disease of 5 continuous or 8 cumulative clock hours (1-12) of ROP involvement

Treatment
- threshold disease is treated with cryotherapy or laser (laser is now the standard treatment, with better refractive outcome); more recently, off-label anti-VEGF intravitreal injections
- ROP beyond threshold level is either watched carefully (usually stage 4A) or treated with vitrectomy/scleral buckle

Prognosis
- higher incidence of myopia among ROP infants, even if treated successfully
- stage 4B and 5 have poor prognosis for visual outcome despite treatment

Nasolacrimal System Defects
- congenital obstruction of the nasolacrimal duct (failure of canalization), usually occurs at 1-2 mo of age
- epiphora, crusting, discharge, recurrent conjunctivitis
- can have reflux of mucopurulent material from lacrimal punctum when pressure is applied over lacrimal sac

Treatment
- massage over lacrimal sac at medial corner of eyelid
- vast majority spontaneously resolve in 9-12 mo, otherwise consider referral for duct probing

Ophthalmia Neonatorum
- newborn conjunctivitis in first month of life
- causes
  - chemical/toxic: silver nitrate, erythromycin (secondary to prophylaxis, self-limiting)
  - infectious: bacterial (e.g. N. gonorrhoeae – most common, C. trachomatis), herpes simplex virus
- diagnose using stains and cultures

Treatment
- systemic antibiotics with possible hospitalization if infectious etiology
- topical prophylaxis, most commonly with erythromycin (or silver nitrate), is required by law at birth

Congenital Glaucoma
- due to inadequate development of the filtering mechanism of the anterior chamber angle

Clinical Features
- cloudy cornea, increased IOP
- photophobia, epiphora
- buphthalmos (large cornea, “ox eye”, secondary to increased IOP), blepharospasm

Treatment
- filtration surgery is required soon after birth to prevent blindness

Ocular Trauma

Blunt Trauma
- caused by blunt object such as fist
- history: injury, ocular history, drug allergy, tetanus status
- exam: VA first, pupil size and reaction, EOM (diplopia), external and slit-lamp exam, ophthalmoscopy
- if VA normal or slightly reduced, globe less likely to be perforated
- if VA reduced may be perforated globe, corneal abrasion, lens dislocation, retinal tear
- bone fractures
  - blow out fracture: restricted EOM, diplopia, enophthalmos (sunken eye)
  - ethmoid fracture: subcutaneous emphysema of lid
- lids: swelling, laceration, emphysema
• conjunctiva: subconjunctival hemorrhage
• cornea: abrasion – detect with fluorescein staining and cobalt blue filter using slit-lamp or ophthalmoscope
• anterior chamber: assess depth, hyphema, hypopyon
• iris: prolapse, iritis
• lens: cataract, dislocation
• retinal tear/detachment

**Penetrating Trauma**

- include ruptured globe ± prolapsed iris, intraocular foreign body
- rule out intraocular foreign body, especially if history of “metal striking metal”, CT orbit

**OCULAR EMERGENCY:** initial management - REFER IMMEDIATELY
- ABCs
  - don’t press on eye globe!
  - don’t check IOP if possibility of globe rupture
- check vision, diplopia
- apply rigid eye shield to minimize further trauma
- keep head elevated 30°-45° to keep IOP down
- keep NPO
- tetanus status
- give IV antibiotics
  - selecting appropriate agents depends on the mechanism of injury; Gram-positive bacteria are more commonly involved than Gram-negative; retained intraocular foreign objects increase the risk of infections with Bacillus species, whereas exposure to vegetable matter increase the risk of a fungal etiology

**Hyphema**

- blood in anterior chamber, often due to damage to root of the iris
- may occur with blunt trauma

**Treatment**
- refer to ophthalmology
- shield and bedrest x 5 d or as determined by ophthalmologist
- sleep with head upright
- may need surgical drainage if hyphema persists or if re-bleed

**Complications**
- risk of re-bleed highest on d 2-5, resulting in secondary glaucoma, corneal staining, and iris necrosis
- never prescribe Aspirin®, as it increases the risk of a re-bleed

**Blow-Out Fracture**

- see Plastic Surgery, PL33
- blunt trauma causing fracture of orbital floor and herniation of orbital contents into maxillary sinus
- orbital rim remains intact
- inferior rectus and/or inferior oblique muscles may be incarcerated at fracture site
- infraorbital nerve courses along the floor of the orbit and may be damaged

**Clinical Features**
- pain and nausea at time of injury
- diplopia, restriction of EOM
- infraorbital and upper lip paresthesia (CN V2)
- enophthalmos (sunken eye), periorbital ecchymoses

**Investigations**
- plain films: Waters’ view and lateral
- CT: anteroposterior and coronal view of orbits

**Treatment**
- refrain from coughing, blowing nose
- systemic antibiotics may be indicated
- surgery if fracture >50% orbital floor, diplopia not improving, or enophthalmos >2 mm
- may delay surgery if the diplopia improves
Chemical Burns

- alkali burns have a worse prognosis than acid burns because acids coagulate tissue and inhibit further corneal penetration
- poor prognosis if cornea opaque, likely irreversible stromal damage
- even with a clear cornea initially, alkali burns can progress for weeks (thus, very guarded prognosis)

Treatment
- immediately irrigate at site of accident with water or buffered solution
  - irrigate with eyelids retracted in emergency department with IV drip until pH physiologic
  - swab upper and lower fornices to remove possible particulate matter
- do not attempt to neutralize an acid with a base, or vice versa
- cycloplegic drops to decrease iris spasm (pain) and prevent secondary glaucoma (due to posterior synechiae formation)
- topical antibiotics and patching
- topical steroids (by ophthalmologist) to decrease inflammation, use for <2 wk (in the case of a persistent epithelial defect)

Ocular Drug Toxicity

Table 12. Drugs with Ocular Toxicity

<table>

TOPICAL OCULAR DIAGNOSTIC DRUGS

**Fluorescein Dye**
- water soluble orange-yellow dye
- green under cobalt blue light (ophthalmoscope or slit-lamp)
- absorbed in areas of epithelial loss (ulcer or abrasion)
- also stains mucus and contact lenses

**Rose Bengal Stain**
- stains devitalized epithelial cells and mucus

**Anesthetics**
- e.g. proparacaine HCl 0.5%, tetracaine 0.5%
- indications: removal of foreign body and sutures, tonometry, examination of painful cornea
- toxic to corneal epithelium (inhibit mitosis and migration) and can lead to corneal ulceration and scarring with prolonged use, therefore NEVER prescribe

**Mydriatics**
- dilate pupils
  - cholinergic blocking (e.g. tropicamide – Mydriacyl®)
    - dilation plus cycloplegia (loss of accommodation) by paralysis of iris sphincter and the ciliary body
    - indications: refraction, ophthalmoscopy, therapy for iritis
  - adrenergic stimulating (e.g. phenylephrine HCl 2.5%)
    - stimulate pupillary dilator muscles, no effect on accommodation
    - usually used with tropicamide for additive effects
  - side effects: HTN, tachycardia, arrhythmias

Teal: Prostaglandins
Orange: Carbonic Anhydrase Inhibitors
Tan: Fluoroquinolones
Grey: NSAIDs
Pink: Anti-inflammatories, Steroids
WET AGE-RELATED MACULAR DEGENERATION MEDICATIONS

VEGF Inhibitors
- block VEGF which prevents ocular angiogenesis and further development of choroidal neovascularization
- administered via intravitreal injections
- pegaptanib (Macugen®) is a selective anti-VEGF targeting VEGF isoform 165 (no longer widely used)
- ranibizumab (Lucentis®) is a non-selective anti-VEGF agent
- aflibercept (Eylea®) is another non-selective anti-VEGF agent, but is only FDA approved for metastatic breast cancer, colorectal cancer, and non-small cell lung cancer; therefore, its widespread ophthalmologic use is off-label

TOPICAL OCULAR THERAPEUTIC DRUGS

NSAIDs
- used for less serious chronic inflammatory conditions
- e.g. ketorolac (Acular®), diclofenac (Voltaren®), nepafenac (Nevanac®) drops

Anti-Histamines
- used to relieve red and itchy eye, often in combination with decongestants
- sodium cromoglycate – stabilizes membranes

Decongestants
- weak adrenergic stimulating drugs (vasoconstrictor)
- e.g. naphazoline, phenylephrine (Isopto Frin®)
- rebound vasodilation with overuse; rarely can precipitate angle closure glaucoma

Antibiotics
- indications: bacterial conjunctivitis, keratitis, or blepharitis
- commonly as topical drops or ointments, may give systemically
- e.g. sulfonamide (sodium sulfacetamide, sulfisoxazole), gentamicin (Garamycin®), erythromycin, tetracycline, bacitracin polymyxin B, fluoroquinolones (ciprofloxacin [Ciloxan®], ofloxacin [Ocuflow®], moxifloxacin [Vigamox®], gatifloxacin [Zymar®])

Corticosteroids
- e.g. fluorometholone (FML®), betamethasone, dexamethasone (Maxidex®), prednisolone (Predsol® 0.5%, Pred Forte® 1%), rimexolone (Vexol®), loteprednol etabonate 0.5% (Lotamax®), difluprednate (Durezol®)
- primary care physicians should avoid prescribing topical corticosteroids due to risk of glaucoma, cataracts, and reactivation of HSV keratitis
- complications
  - potentiates HSV keratitis and fungal keratitis as well as masking symptoms
  - increased IOP, more rapidly in steroid responders (within weeks)
  - posterior subcapsular cataract (within months)

Fractures – General Principles

Fracture Description

1. Name of Injured Bone

2. Integrity of Skin/Soft Tissue
   • closed: skin/soft tissue over and near fracture is intact
   • open: skin/soft tissue over and near fracture is lacerated or abraded, fracture exposed to outside environment, or contaminated (i.e. bowel)
   • signs: continuous bleeding from puncture site or fat droplets in blood are suggestive of an open fracture

3. Location (Figure 5)
   • epiphyseal: end of bone, forming part of the adjacent joint
   • metaphysal: the flared portion of the bone at the ends of the shaft
   • diaphyseal: the shaft of a long bone (proximal, middle, distal)
   • physis: growth plate
4. Orientation/Fracture Pattern (Figure 4)
- transverse: fracture line perpendicular (<30° of angulation) to long axis of bone; result of direct high energy force
- oblique: angular fracture line (30° - 60° of angulation); result of angulation and compressive force, high energy
- butterfly: fracture site fragment which looks like a butterfly
- segmental: a separate segment of bone bordered by fracture lines; result of high energy force
- spiral: complex, multi-planar fracture line; result of rotational force, low energy
- comminuted/multi-fragmentary: >2 fracture fragments
- intra-articular: fracture line crosses articular cartilage and enters joint
- avulsion: tendon or ligament tears/pulls off bone fragment; often in children, high energy
- compression/impacted: impaction of bone; typical sites are vertebrae or proximal tibia
- torus: a buckle fracture of one cortex, often in children (Figure 49)
- greenstick: an incomplete fracture of one cortex, often in children (Figure 49)
- pathologic: fracture through bone weakened by disease/tumour

5. Alignment of Fracture Fragments
- non-displaced: fracture fragments are in anatomic alignment
- displaced: fracture fragments are not in anatomic alignment
- distracted: fracture fragments are separated by a gap (opposite of impacted)
- impacted: fracture fragments are compressed, resulting in shortened bone
- angulated: direction of fracture fragments is separated by a gap (opposite of impacted)
- angulated: direction of fracture apex (e.g. varus/valgus)
- translated/shifted: percentage of overlapping bone at fracture site
- rotated: fracture fragment rotated about long axis of bone

---

**Approach to Fractures**

1. Clinical Assessment
- ABCs, primary survey, and secondary survey (ATLS protocol)
  - rule out other fractures/injuries
  - rule out open fracture
- AMPLE history (minimum): Allergies, Medications, Past medical history, Last meal, Events surrounding injury
  - mechanism of injury
  - previous significant injury or surgery to affected area
  - consider pathologic fracture with history of only minor trauma
- Physical exam: look (deformity, soft tissue integrity); feel (maximal tenderness, NVS-document best possible neurovascular exam, avoid ROM/moving injured area to prevent exacerbation)

2. Analgesia
3. Imaging (see Orthopedic X-Ray Imaging, OR7)
4. Splint Extremity
5. Management: Closed vs. Open Reduction
   1. obtain the reduction (see appropriate IV sedation, see Table 27, OR48)
     - closed reduction
       - apply traction in the long axis of the limb
       - reverse the mechanism that produced the fracture
       - reduce with IV sedation and muscle relaxation (fluoroscopy can be used if available)
     - indications for open reduction
       - “NO CAST”
       - other indications include
         - failed closed reduction
         - not able to cast or apply traction due to site (e.g. hip fracture)
         - pathologic fractures
       - potential for improved function with ORIF
     - ALWAYS re-check and document NVS after reduction and obtain post-reduction x-ray

---

**Displacement**
- Refers to position of the distal fragment relative to the proximal fragment

**Varus/Valgus Angulation**
- Varus = Apex away from midline
- Valgus = Apex toward midline

**Approach to Fractures**

**Figure 5. Schematic diagram of the long bone**

**Quick Motor Nerve Exam**
- Thumbs Up*: PIN (Median Nerve)
- "OK Sign": AIN (Median Nerve)
- "Spread Fingers": Ulnar Nerve

**X-Ray Rule of 2s**
- 2 sides = bilateral
- 2 views = AP + lateral
- 2 joints = joint above + below
- 2 times = before + after reduction

**Reasons for Splinting**
- Pain control
- Reduces further damage to vessels, nerves, and skin and may improve vascular status
- Decreases risk of inadvertently converting closed to open fracture
- Facilitates patient transport

**Indications for Open Reduction**
- NO CAST
- Non-union
- Open fracture
- Neurovascular Compromise
- Displaced intra-Articular fracture
- Salter-Harris 3,4,5
- PolyTrauma

**Buck's Traction**
- A system of weights, pulleys, and ropes that are attached to the end of a patient’s bed exerting a longitudinal force on the distal end of a fracture, improving its length, alignment, and rotation
2. maintain the reduction
   • external stabilization: splints, casts, traction, external fixator
   • internal stabilization: percutaneous pinning, extramedullary fixation (screws, plates, wires), IM fixa tion (rods)
   • follow-up: evaluate bone healing
3. rehabilitate to regain function and avoid joint stiffness

Fracture Healing

Normal Healing

<table>
<thead>
<tr>
<th>Period</th>
<th>Description</th>

Articular Cartilage

Properties

• 2-4 mm layer covering ends of articulating bones, provides nearly frictionless surface
• avascular (nutrition from synovial fluid), aneural, alymphatic

ARTICULAR CARTILAGE DEFECTS

Etiology

• overt trauma, repetitive minor trauma (such as repetitive ankle sprains or patellar maltracking); common sports injury
• degenerative conditions such as early stage OA or osteochondritis dissecans

Clinical Features

• similar to symptoms of OA (joint line pain with possible effusion, etc.)
• often have predisposing factors, such as ligament injury, malalignment of the joint (varus/valgus), obesity, bone deficiency (AVN, osteochondritis dissecans, ganglion bone cysts), inflammatory arthropathy, and familial osteoarthropathy
• may have symptoms of locking or catching related to the torn/displaced cartilage

Investigations

• x-ray (to rule out bony defects and check alignment)
• MRI
• diagnostic arthroscopy (treatment is often guided by what is seen during arthroscopy)

<td>Erosion of cartilage down to bone</td>
</tr>
</tbody>
</table>

Treatment
- individualized
  - patient factors (age, skeletal maturity, activity level, etc.)
  - defect factors (Outerbridge Classification, subchondral bone involvement, etc.)
- non-operative
  - rest, NSAIDs, bracing
- operative
  - microfracture, osteochondral grafting (autograft or allograft) autologous chondrocyte implantation

Orthopedic X-Ray Imaging

General Principles
- x-ray 1 joint above and 1 below
  - obtain at least 2 orthogonal views ± specialized views

</table>
Trauma Patient Workup

Etiology
- high energy trauma e.g. MVC, fall from height
- may be associated with spinal injuries or life-threatening visceral injuries

Clinical Features
- local swelling, tenderness, deformity of the limbs, and instability of the pelvis or spine
- decreased level of consciousness, hypotension/hypovolemia
- consider involvement of EoOH or other substances

Investigations
- trauma survey (see Emergency Medicine, ER7, ER15)
- x-rays: lateral cervical spine, AP chest, AP pelvis, AP and lateral all of bones suspected to be injured
- CT is also utilized to inspect for musculoskeletal injuries in the trauma setting
- other views of pelvis: AP, inlet, and outlet; Judet views for acetabular fracture (for Classification of Pelvic Fractures see Table 18, OR27)

Treatment
- ABCDEs and initiate resuscitation for life-threatening injuries
- assess genitourinary injury (rectal exam/vaginal exam mandatory)
- external or internal fixation of all fractures
- DVT prophylaxis

Complications
- hemorrhage – life-threatening (may produce signs and symptoms of hypovolemic shock)
- fat embolism syndrome (SOB, hypoxemia, petechial rash, thrombocytopenia, and neurological symptoms)
- venous thrombosis – DVT and PE
- bladder/urethral/bowel injury
- neurological damage
- persistent pain/stiffness/limp/weakness in affected extremities
- post-traumatic OA of joints with intra-articular fractures
- sepsis if missed open fracture

Open Fractures
- fractured bone and hematoma in communication with the external or contaminated environment

Emergency Measures
- ABCs, primary survey, and resuscitation as needed
- removal of obvious foreign material
- irrigate with normal saline if grossly contaminated
- cover wound with sterile dressings
- immediate IV antibiotics
- tetanus toxoid or immunoglobulin as needed
- reduce and splint fracture
- NPO and prepare for OR (blood work, consent, ECG, CXR)
  - operative irrigation and debridement within 6-8 h to decrease risk of infection
  - traumatic wound often left open to drain but vacuum-assisted closure dressing may be used
  - re-examine with repeat irrigation and debridement in 48 h

*Any high energy, comminuted fracture, shotgun, farmyard/soil/water contamination exposure to oral flora, or fracture >8 h old is immediately classified as Grade II

Antibiotics for Preventing Infection in Open Limb Fractures
Cochrane Qs Syst Rev 2004;1:CD0003764
Purpose: To review the evidence regarding the effectiveness of antibiotics in the initial treatment of open fractures of the limbs.
Methods: Randomized or quasi randomized controlled trials comparing antibiotic treatment with placebo or no treatment in preventing acute wound infection were identified and reviewed. Data were extracted and pooled for analysis.
Results: Eight studies (n=1,106) were reviewed. The use of antibiotics had a protective effect against early infection compared with no antibiotics or placebo (RRI=0.43, 95% CI 0.29, 0.65; ARR=0.07, 95% CI 0.03-0.15).
Conclusions: Antibiotics reduce the incidence of early infections in open fractures of the limbs.
Cauda Equina Syndrome

- see Neurosurgery, NS27

Compartment Syndrome

- increased interstitial pressure in an anatomical compartment (forearm, calf) where muscle and tissue are bounded by fascia and bone (fibro-osseous compartment), with little room for expansion
- interstitial pressure exceeds capillary perfusion pressure, leading to muscle necrosis (in 4-6 h) and eventually nerve necrosis

Etiology

- intracompartmental
  - fracture (particularly tibial shaft or paediatric supracondylar and forearm fractures)
  - reperfusion injury, crush injury, or ischemia
- extracompartmental: constrictive dressing (circumferential cast), poor position during surgery, circumferential burn

Clinical Features

- pain out of proportion to injury (typically first symptom)
- pain with active contraction of compartment
- pain with passive stretch (most sensitive)
- swollen, tense compartment
- suspicious history

- 5 Ps: late sign – do not wait for these to develop to make the diagnosis!

Investigations

- usually not necessary, as compartment syndrome is a clinical diagnosis
- in children or unconscious patients where clinical exam is unreliable, compartment pressure monitoring with catheter AFTER clinical diagnosis is made (normal = 0 mmHg; elevated ≥30 mmHg or [measured pressure – dBP] ≤30 mmHg)

Treatment

- non-operative
  - remove constrictive dressings (casts, splints), elevate limb at the level of the heart
- operative
  - urgent fasciotomy
  - 48-72 h post-operative: wound closure ± necrotic tissue debridement

Complications

- Volkmann’s ischemic contracture: ischemic necrosis of muscle, followed by secondary fibrosis, and finally calcification; especially following supracondylar fracture of humerus
- rhabdomyolysis, renal failure secondary to myoglobinuria

Osteomyelitis

- bone infection with progressive inflammatory destruction

Etiology

- most commonly caused by *S. aureus*
- mechanism of spread: hematogenous (most common) vs. direct inoculation vs. contiguous focus
- risk factors: recent trauma/surgery, immunocompromised patients, DM, IV drug use, poor vascular supply, peripheral neuropathy

- Plain Film Findings of Osteomyelitis
  - Soft tissue swelling
  - Lytic bone destruction*
  - Periostial reaction (formation of new bone, especially in response to #)*
*Generally not seen on plain films until 10-12 d after onset of infection
Clinical Features
- symptoms: pain and fever
- on exam: erythema, tenderness, edema common ± abscess/draining sinus tract; impaired function/WB

Diagnosis
- see Medical Imaging, MI23
- workup includes: WBC and differential, ESR, CRP, blood culture, aspirate culture/bone biopsy

Table 6. Treatment of Osteomyelitis

</tr>
<tr>
<td>± hardware removal (if present)</td>
<td></td>
</tr>
</tbody>
</table>

Septic Joint
- joint infection with progressive destructive if left untreated

Etiology
- most commonly caused by S. aureus in adults
- consider coagulase-negative Staphylococcus in patients with prior joint replacement
- consider Neisseria gonorrhoeae in sexually active adults and newborns
- most common route of infection is hematogenous
- risk factors: young/elderly (age >80 yr), RA, prosthetic joint, recent joint surgery, skin infection/ulcer, IV drug use, previous intra-articular corticosteroid injection, immune compromise (cancer, DM, alcoholism)

Clinical Features
- inability/refusal to bear weight, localized joint pain, erythema, warmth, swelling, pain on active and passive ROM, ± fever

Investigations
- x-ray (to rule out fracture, tumour, metabolic bone disease), ESR, CRP, WBC, blood cultures
- joint aspirate: cloudy yellow fluid, WBC >50,000 with >90% neutrophils, protein level >4.4 mg/dL, joint glucose level <60% blood glucose level, no crystals, positive Gram stain results
- listen for heart murmur (to reduce suspicion of infective endocarditis, use Duke Criteria)

Treatment
- IV antibiotics, empiric therapy (based on age and risk factors), adjust following joint aspirate C&S results
- non-operative
  - therapeutic joint aspiration, serially if necessary (if early diagnosis and joint superficial)
  - operative
    - arthroscopic/open irrigation and irrigation and drainage ± decompression

Shoulder Dislocation

complete separation of the glenohumeral joint; may be anterior or posterior

Investigations
- anterior dislocation X-rays: AP, trans-scapular, axillary views
- posterior dislocation X-rays: AP, trans-scapular, axillary; or CT scan

Rapid progression of signs and symptoms (over hours) necessitates need for serial examinations

Acute osteomyelitis is a medical emergency which requires an early diagnosis and appropriate antimicrobial and surgical treatment

Most commonly affected joints in descending order
knee → elbow → ankle → sternoclavicular joint

Plain Film Findings in a Septic Joint
- Early (0-3 d): usually normal; may show soft-tissue swelling or joint space widening from localized edema
- Late (4-6 d): joint space narrowing and destruction of cartilage

Serial C-reactive protein (CRP) can be used to monitor response to therapy

Does This Adult Patient Have Septic Arthritis?
JAMA 2007;297(13):1478-1488

Purpose: To review the accuracy and precision of the clinical evaluation for the diagnosis of nongonococcal bacterial arthritis.

Methods: Review of 14 studies including 6242 patients of which 653 had positive synovial culture (gold standard diagnostic tool for septic arthritis).

Results/Conclusions: Age, diabetes mellitus, rheumatoid arthritis, joint surgery, hip or knee prosthesis, skin infection, and human immunodeficiency virus type 1 infection significantly increase the probability of septic arthritis. Joint pain, history of joint swelling, and fever are useful clinical findings in identifying patients with a monoarticular arthritis who may have septic arthritis. Laboratory findings from an arthrocentesis are also required and helpful prior to Gram stain and culture. The presence of increased WBC increases the likelihood ratio (for counts <25,000/µL: LR, 0.32; 95% CI, 0.23-0.43; for counts ≥25,000/µL: LR, 2.9; 95% CI, 2.5-3.4; for counts ≥100,000/µL: LR, 12.5-48.4). A polymorphonuclear cell count of ≥90% increases the LR of septic arthritis by 3.4, while a PMN cell count of <90% reduces the LR by 0.34.

Posterior Shoulder Dislocation

Up to 60-80% are missed on initial presentation due to poor physical exam and radiographs

There are 4 Joints in the Shoulder
- glenohumeral, AC, sternoclavicular (SC), scapulothoracic

</tbody>
</table>

**Prognosis**
- recurrence rate depends on age of first dislocation
- <20 yr = 65-95%; 20-40 yr = 60-70%; >40 yr = 2-4% 

**Specific Complications**
- rotator cuff or capsular or labral tear (Bankart/SLAP lesion), shoulder stiffness
- injury to axillary nerve/artery, brachial plexus
- recurrent/unreduced dislocation (most common complication)
Rotator Cuff Disease

- rotator cuff consists of 4 muscles that act to stabilize the humeral head within the glenoid fossa

**Table 8. Rotator Cuff Muscles (SITS)**

SPECTRUM OF DISEASE: IMPINGEMENT, TENDONITIS, MICRO OR MACRO TEARS

**Etiology**
- anything that leads to a narrow subacromial space
- most commonly, a relative imbalance of rotator cuff and larger shoulder muscles, allowing for superior translation and subsequent wear of the rotator cuff muscle tendons
  - glenohumeral muscle weakness leading to abnormal motion of humeral head
  - scapular muscle weakness leading to abnormal motion of acromion
- acromial abnormalities, such as congenital narrow space or osteophyte formation or Type III acromion morphology
  1. outlet/subacromial impingement: “painful arc syndrome”, compression of rotator cuff tendons (primarily supraspinatus) and subacromial bursa between the head of the humerus and the undersurface of the acromion, AC joint, and CA ligament
  2. bursitis and tendonitis
  3. rotator cuff thinning and tear if left untreated

**Clinical Features**
- insidious onset, but may present as an acute exacerbation of chronic disease, night pain, and difficulty sleeping on affected side
- pain worse with active motion (especially overhead); passive movement generally permitted
- weakness and loss of ROM, especially between 90°-130° (e.g. trouble with overhead activities)
- tenderness to palpation over greater tuberosity
- rule out bicep tendinosis: Speed test; SLAP lesion: O’Brien’s test

**Investigations**
- X-ray: AP view may show high riding humerus relative to glenoid, indicating large tear, evidence of chronic tendinitis
- MRI: coronal/sagittal, oblique and axial orientations are useful for assessing full/partial tears and tendinopathy ± arthrogram: geyser sign (injected dye leaks out of joint through rotator cuff tear)
- arthrogram: can assess full thickness tears, difficult to assess partial tears

**Bigliani Classification of Acromion Morphology**
- Type I – flat
- Type II – curved
- Type III – hooked

**Screening Out Rotator Cuff Tears**
- No night pain (SN 87.7%)
- No painful arc (SN 91.5%)
- No impingement signs (SN 97.2%)
- No weakness
*Returning to the bedside: Using the history and physical examination to identify rotator cuff tears
JAM Geri Soc 2000;48:1633-1637
Treatment

- **non-operative**
  - for mild (“wear”) or moderate (“tear”) cases
  - physiotherapy, NSAIDs ± steroid injection
- **operative**
  - indication: severe (“repair”)
  - impingement that is refractory to 2-3 mo physiotherapy and 1-2 corticosteroid injections
  - arthroscopic or open surgical repair (i.e. acromioplasty, rotator cuff repair)

### Table 9. Rotator Cuff Special Tests

<tr>
<td>O’Brien’s Test</td>
<td>SLAP lesion: forward flexion of the arm to 90 degrees while keeping the arm extended. Arm is adducted 10-15 degrees. Internally rotate the arm so thumb is facing down and apply a downward force. Repeat the test with arm externally rotated</td>
<td>Pain or clicking in the glenohumeral joint in internal rotation but not external rotation</td>
</tr>
</tbody>
</table>

Figure 13. Rotator cuff tests
**Acromioclavicular Joint Pathology**

- subluxation or dislocation of AC joint
- 2 main ligaments attach clavicle to scapula: AC and CC ligaments

**Mechanism**
- fall onto shoulder with adducted arm or direct trauma to point of shoulder

**Clinical Features**
- pain with adduction of shoulder and/or palpation over AC joint
- palpate step deformity between distal clavicle and acromion (with dislocation)
- limited ROM

**Investigations**
- X-rays: bilateral AP, Zanca view (10-15° cephalic tilt), axillary

**Treatment**
- non-operative
  - sling 1-3 wk, ice, analgesia, early ROM and rehabilitation
- operative
  - indication: Rockwood Class IV-VI (III if labourer or high level athlete)
  - number of different approaches involving AC/CC ligament reconstruction or screw/hook plate insertion

**Table 10. Rockwood Classification of Acromioclavicular Joint Separation**

<table>
<thead>
<tr>
<th>Grade</th>

<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>Joint sprain, absence of complete tear of either ligament</td>
<td>Non-operative</td>
</tr>
<tr>
<td>II</td>
<td>Complete tear of AC ligament, incomplete tear of CC ligament, without marked elevation of lateral clavicular head</td>
<td>Non-operative</td>
</tr>
<tr>
<td>III</td>
<td>Complete tear of AC and CC ligaments, ≥5 mm elevation at AC joint, superior aspect of acromion is below the inferior aspect of the clavicle</td>
<td>Most non-operative, operative if labourer or high level athlete Will heal with step deformity, although most fully functional in 4-6 mo</td>
</tr>
<tr>
<td>IV-VI</td>
<td>Based on the anatomical structure the displaced clavicle is in proximity to</td>
<td>Operative in most cases</td>
</tr>
</tbody>
</table>

**Clavicle Fracture**

- incidence: proximal (5%), middle (80%), or distal (15%) third of clavicle
- common in children (unites rapidly without complications)

**Mechanism**
- fall on shoulder (87%), direct trauma to clavicle (7%), FOOSH (6%)

**Clinical Features**
- pain and tenting of skin
- arm is clasped to chest to splint shoulder and prevent movement

**Investigations**
- evaluate NVS of entire upper limb
- X-ray: AP, 45° cephalic tilt (superior/inferior displacement), 45° caudal tilt (AP displacement) CT: useful for medial phyleal fractures and sternoclavicular injury

**Treatment**
- medial and middle-third clavicle fractures
  - simple sling x 1-2 wk
  - early ROM and strengthening once pain subsides
  - if fracture is shortened >2 cm, consider ORIF
- distal-third clavicle fractures
  - undisplaced (with ligaments intact): sling x 1-2 wk
  - displaced (CC ligament injury): ORIF

**Specific Complications** *(see General Fracture Complications, OR6)*
- cosmetic bump usually only complication
- shoulder stiffness, weakness with repetitive activity
- pneumothorax, brachial plexus injuries, and subclavian vessel (all very rare)
Frozen Shoulder (Adhesive Capsulitis)

- disorder characterized by progressive pain and stiffness of the shoulder, usually resolving spontaneously after 18 mo

**Mechanism**
- primary adhesive capsulitis
  - idiopathic, usually associated with DM
  - usually resolves spontaneously in 9-18 mo
- secondary adhesive capsulitis
  - due to prolonged immobilization
  - shoulder-hand syndrome: CRPS/RSD characterized by arm and shoulder pain, decreased motion, and diffuse swelling
  - following MI, stroke, shoulder trauma
  - poorer outcomes

**Clinical Features**
- gradual onset (weeks to months) of diffuse shoulder pain with:
  - decreased active AND passive ROM
  - pain worse at night and often prevents sleeping on affected side
  - increased stiffness as pain subsides: continues for 6-12 mo after pain has disappeared

**Investigations**
- X-ray: AP (neutral, internal/external rotation), scapular Y, axillary
  - may be normal, or may show demineralization from disease

**Treatment**
- freezing phase
  - active and passive ROM (physiotherapy)
  - NSAIDs and steroid injections if limited by pain
- thawing phase
  - manipulation under anesthesia and early physiotherapy
  - arthroscopy for debridement/decompression

Humerus

Proximal Humeral Fracture

**Mechanism**
- young: high energy trauma (MVC)
- elderly: FOOSH from standing height in osteoporotic individuals

**Clinical Features**
- proximal humeral tenderness, deformity with severe fracture, swelling, painful ROM, bruising extends down arm and chest

**Investigations**
- test axillary nerve function (deltoid contraction and skin over deltoid)
- X-rays: AP, trans-scapular, axillary are essential
- CT scan: to evaluate for articular involvement and fracture displacement

**Classification**
- Neer classification is based on 4 fracture locations or ‘parts’
- displaced: displacement >1 cm and/or angulation >45°
- the Neer system regards the number of displaced fractures, not the fracture line, in determining classification
- ± dislocated/subluxed: humeral head dislocated/subluxed from glenoid

**Treatment**
- treat osteoporosis if needed
- non-operative
  - nondisplaced: broad arm sling immobilization, begin ROM within 14 d to prevent stiffness
  - minimally displaced (85% of patients) - closed reduction with sling immobilization x 2 wk, gentle ROM
- operative
  - ORIF (anatomic neck fractures, displaced, associated dislocated glenohumeral joint)
  - hemiarthroplasty or reverse TSA may be necessary, especially in elderly

Specific Complications (see General Fracture Complications, OR6)
- AVN, nerve palsy (45%; typically axillary nerve), malunion, post-traumatic arthritis

Conditions Associated with an Increased Incidence of Adhesive Capsulitis
- Prolonged immobilization (most significant)
- Female gender
- Age >49 yr
- DM (5x)
- Cervical disc disease
- Hyperthyroidism
- Stroke
- MI
- Trauma and surgery
- Autoimmune disease

Stages of Adhesive Capsulitis
1. Freezing phase: gradual onset, diffuse pain (lasts 6-9 mo)
2. Frozen phase: decreased ROM impacting functioning (lasts 4-9 mo)
3. Thawing phase: gradual return of motion (lasts 5-26 mo)

Neer Classification
- Based on 4 parts of humerus
  - Greater Tuberosity
  - Lesser Tuberosity
  - Humeral Head
  - Shaft
- One-part fracture: any of the 4 parts with none displaced
- Two-part fracture: any of the 4 parts with 1 displaced
- Three-part fracture: displaced fracture of surgical neck + displaced greater tuberosity or lesser tuberosity
- Four-part fracture: displaced fracture of surgical neck + both tuberosities

Anatomic neck fractures disrupt blood supply to the humeral head and AVN of the humeral head may ensue
Humerus

**Humeral Shaft Fracture**

**Mechanism**
- high energy: direct blows/MVC (especially young); low energy: FOOSH, twisting injuries, metastases (in elderly)

**Clinical Features**
- pain, swelling, weakness ± shortening, motion/crepitus at fracture site
- must test radial nerve function before and after treatment: look for drop wrist, sensory impairment, dorsum of hand

**Investigations**
- X-ray: AP and lateral radiographs of the humerus, including the shoulder and elbow joints

**Treatment**
- in general, humeral shaft fractures are treated non-operatively
- non-operative
  - ± reduction; can accept deformity due to compensatory ROM of shoulder
  - hanging cast (weight of arm in cast provides traction across fracture site) with collar and cuff sling immobilization until swelling subsides, then Sarmiento functional brace, followed by ROM
- operative
  - indications: see “NO CAST” (OR5), pathological fracture, “floating elbow” (simultaneous unstable humeral and forearm fractures)
  - ORIF: plating (most common), IM rod insertion, external fixation

**Specific Complications** (see General Fracture Complications, OR6)
- radial nerve palsy: expect spontaneous recovery in 3-4 mo, otherwise send for EMG
- non-union: most frequently seen in middle 1/3
- decreased ROM
- compartment syndrome

**Distal Humeral Fracture**

**Mechanism**
- young: high energy trauma (MVC)
- elderly: FOOSH

**Clinical Features**
- elbow pain and swelling
- assess brachial artery

**Investigations**
- X-ray: AP and lateral of humerus and elbow
- CT scan: helpful when suspecting shear fracture of capitulum or trochlea

**Classification**
- supracondylar, distal single column, distal bicondylar, and coronal shear fractures

**Treatment**
- goal is to restore ROM 30-130° flexion (unsatisfactory outcomes in 25%)
- non-operative
  - cast immobilization (in supination for lateral condyle fracture; pronation for medial condyle fractures)
- operative
  - indications: displaced, supracondylar, bicondylar
  - closed reduction and percutaneous pinning; ORIF; total elbow arthroplasty (bicondylar in elderly)

The anterior humeral line refers to an imaginary line drawn along the anterior surface of the humeral cortex that passes through the middle third of the capitellum when extended inferiorly. In subtle supracondylar fractures, the anterior humeral line is disrupted, typically passing through the anterior third of the capitellum.
Elbow

Supracondylar Fracture

- subclass of distal humerus fracture: extra-articular, fracture proximal to capitulum and trochlea, usually transverse
- most common in pediatric population (peak age ~7 yr old), rarely seen in adults
- AIN (median nerve) injury commonly associated with extension type

Mechanism
- >96% are extension injuries via FOOSH (e.g. fall off monkey bars); <4% are flexion injuries

Clinical Features
- pain, swelling, point tenderness
- neurovascular injury: assess median and radial nerves, radial artery (check radial pulse)

Investigations
- X-ray: AP lateral of elbow
  - disruption of anterior humeral line suggests supracondylar fracture
  - fat pad sign: a sign of effusion and can be indicative of occult fracture

Treatment
- reduction indications: evidence of arterial obstruction, unacceptable angulation, displaced (>50%) non-operative
  - nondisplaced: long arm plaster slab in 90° flexion x 3 wk
  - operative
    - indications: displaced, vascular injury, open fracture
    - requires percutaneous pinning followed by limb cast with elbow flexed <90°
    - in adults, ORIF is necessary

Specific Complications (see General Fracture Complications, OR6)
- stiffness is most common
- brachial artery injury (kinking can occur if displaced fracture), median or ulnar nerve injury, compartment syndrome (leads to Volkmann’s ischemic contracture), malalignment cubitus varus (distal fragment tilted into varus)

Radial Head Fracture

- a common fracture of the upper limb in young adults

Mechanism
- FOOSH with elbow extended and forearm pronated

Clinical Features
- marked local tenderness on palpation over radial head (lateral elbow)
- decreased ROM at elbow, ± mechanical block to forearm pronation and supination
- pain on pronation/supination

Investigations
- X-ray: enlarged anterior fat pad (“sail sign”) or the presence of a posterior fat pad indicates effusion which could occur with occult radial head fractures

Table 11. Classification and Treatment of Radial Head Fractures

<table>
<thead>
<tr>
<th>Mason Class</th>
<th>Radiographic Description</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Nondisplaced fracture</td>
<td>Elbow slab or sling x 3-5 d with early ROM</td>
</tr>
<tr>
<td>2</td>
<td>Displaced fracture</td>
<td>ORIF: angulation &gt;30°, involves ≥1/3 of the radial head, or ≥3 mm of joint incongruity exists</td>
</tr>
<tr>
<td>3</td>
<td>Comminuted fracture</td>
<td>Radial head excision ± prosthesis (if ORIF not feasible)</td>
</tr>
<tr>
<td>4</td>
<td>Comminuted fracture with posterior elbow dislocation</td>
<td>Radial head excision ± prosthesis</td>
</tr>
</tbody>
</table>

Specific Complications (see General Fracture Complications, OR6)
- myositis ossificans – calcification of muscle
- recurrent instability (if MCL injured and radial head excised)
**Olecranon Fracture**

**Mechanism**
- direct trauma to posterior aspect of elbow (fall onto the point of the elbow) or FOOSH

**Clinical Features**
- localized pain, palpable defect
- ± loss of active extension due to avulsion of triceps tendon

**Investigations**
- X-ray: AP and lateral (require true lateral to determine fracture pattern)

**Treatment**
- non-operative
  - non-displaced (<2 mm, stable): cast x 3 wk (elbow in 90° flexion), then gentle ROM
  - displaced: ORIF (plate and screws or tension band wiring) and early ROM if stable

**Elbow Dislocation**
- third most common joint dislocation after shoulder and patella
  - anterior capsule and collateral ligaments disrupted

**Mechanism**
- elbow hyperextension via FOOSH or valgus/supination stress during elbow flexion
  - usually the radius and ulna are dislocated together, or the radial head dislocates and the ulna remains ("Monteggia")
  - 80% are posterior/posterolateral, anterior are rare and usually devastating

**Clinical Features**
- elbow pain, swelling, deformity
- flexion contracture
- ± absent radial or ulnar pulses

**Investigations**
- x-ray: AP and lateral views

**Treatment**
- assess NVS before reduction: brachial artery, median and ulnar nerves (can become entrapped during manipulation)
- non-operative
  - closed reduction under conscious sedation (post-reduction x-rays required)
  - Parvin's method: patient lies prone with arm hanging down; apply gentle traction downwards on wrist; as olecranon slips distally, gently lift up the arm at elbow to reduce joint
  - long-arm splint with forearm in neutral rotation and elbow in 90° flexion
  - early ROM (<2 wk)
- operative
  - indications: complex dislocation or persistent instability after closed reduction
  - ORIF

**Specific Complications** (see General Fracture Complications, OR6)
- stiffness (loss of extension), intra-articular loose body, neurovascular injury (ulnar nerve, median nerve, brachial artery), radial head fracture
- recurrent instability uncommon

**Epicondylitis**
- lateral epicondylitis = "tennis elbow", inflammation of the common extensor tendon as it inserts into the lateral epicondyle
- medial epicondylitis = "golfer's elbow", inflammation of the common flexor tendon as it inserts into the medial epicondyle

**Mechanism**
- repeated or sustained contraction of the forearm muscles/chronic overuse

**Clinical Features**
- point tenderness over humeral epicondyle and/or distal to it
- pain upon resisted wrist extension (lateral epicondylitis) or wrist flexion (medial epicondylitis)
- generally a self-limited condition, but may take 6-18 mo to resolve
Treatment
- non-operative (very good outcomes)
  - rest, ice, NSAIDs
  - use brace/strap
  - physiotherapy, stretching, and strengthening
  - corticosteroid injection
- operative
  - indication: failed 6-12 mo conservative therapy
  - percutaneous or open release of common tendon from epicondyle

Forearm

Radius and Ulna Shaft Fractures

Mechanism
- high-energy direct or indirect (MVA, fall from height, sports) trauma
- fractures usually accompanied by displacement due to high force

Clinical Features
- deformity, pain, swelling
- loss of function in hand and forearm

Investigations
- X-ray: AP and lateral of forearm ± oblique of elbow and wrist
- CT if fracture is close to joint

Treatment
- goal is anatomic reduction since imperfect alignment significantly limits forearm pronation and supination
- ORIF with plates and screws; closed reduction with immobilization usually yields poor results for displaced forearm fractures (except in children)

Specific Complications (see General Fracture Complications, OR6)
- soft tissue contracture resulting in limited forearm rotation – surgical release of tissue may be warranted

Monteggia Fracture

- fracture of the proximal ulna with radial head dislocation and proximal radioulnar joint injury
- more common and better prognosis in the pediatric age group when compared to adults

Mechanism
- direct blow on the posterior aspect of the forearm
- hyperpronation
- fall on the hyperextended elbow

Clinical Features
- pain, swelling, decreased rotation of forearm ± palpable lump at the radial head
- ulna angled apex anterior and radial head dislocated anteriorly (rarely the reverse deformity occurs)

Investigations
- X-ray: AP, lateral elbow, wrist and forearm

Treatment
- adults: ORIF of ulna with indirect radius reduction in 90% of patients (ORIF of radius if unsuccessful)
- splint and early post-operative ROM if elbow completely stable, otherwise immobilization in plaster with elbow flexed for 6 wk
- pediatrics: attempt closed reduction and immobilization in plaster with elbow flexed for Bado Type I-III, surgery for Type IV

Specific Complications (see General Fracture Complications, OR6)
- PIN: most common nerve injury; observe for 3 mo as most resolve spontaneously
- radial head instability/redislocation
- radioulnar synostosis
**Nightstick Fracture**
- isolated fracture of ulna without dislocation of radial head

**Mechanism**
- direct blow to forearm (e.g., holding arm up to protect face)

**Treatment**
- non-operative
  - non-displaced
  - below elbow cast (x 10 d), followed by forearm brace (~8 wk)
- operative
  - displaced
  - ORIF if >50% shaft displacement or >10° angulation

**Galeazzi Fracture**
- fracture of the distal radial shaft with disruption of the DRUJ
- most commonly in the distal 1/3 of radius near junction of metaphysis/diaphysis

**Mechanism**
- hand FOOSH with axial loading of pronated forearm or direct wrist trauma

**Clinical Features**
- pain, swelling, deformity, and point tenderness at fracture site

**Investigations**
- X-ray: AP, lateral elbow, wrist, and forearm
  - shortening of distal radius >5 mm relative to the distal ulna
  - widening of the DRUJ space on AP
  - dislocation of radius with respect to ulna on true lateral

**Treatment**
- all cases are operative
  - ORIF of radius; afterwards, assess DRUJ stability by balloting distal ulna relative to distal radius
  - if DRUJ is stable and reducible, splint for 10-14 d with early ROM encouraged
  - if DRUJ is unstable, ORIF or percutaneous pinning with long arm cast in supination x 6 wk

**Wrist**

**Colles’ Fracture**
- extra-articular transverse distal radius fracture (~2 cm proximal to the radiocarpal joint) with dorsal displacement ± styloid fracture
- most common fracture in those >40 yr, especially in women and those with osteoporotic bone

**Mechanism**
- FOOSH

**Clinical Features**
- “dinner fork” deformity
- swelling, ecchymosis, tenderness

**Investigations**
- X-ray: AP and lateral wrist

**Treatment**
- goal is to restore radial height (13 mm), radial inclination (22°), volar tilt (11°), as well as DRUJ stability and useful forearm rotation
  - non-operative
    - closed reduction (think opposite of the deformity)
      - hematoma block (sterile prep and drape, local anesthetic injection directly into fracture site) or conscious sedation
      - closed reduction: 1) traction with extension (exaggerate injury), 2) traction with ulnar deviation, pronation, flexion (of distal fragment – not at wrist)
      - dorsal slab/below elbow cast for 5-6 wk
      - x-ray at 1 wk, 3 wk, and at cessation of immobilization to ensure reduction is maintained
    - obtain post-reduction films immediately; repeat reduction if necessary
  - ORIF Colles’ Fracture if Post-Reduction Demonstrates
    - Radial shortening >3 mm or,
    - Dorsal tilt >10° or,
    - Intra-articular displacement/step-off >2 mm

**Indications for surgical management of Colles’ Fracture**
- Displaced intra-articular fracture
- Comminuted
- Severe osteoporosis
- Dorsal angulation >5° or volar tilt >20°
- >5 mm radial shortening
Smith’s Fracture

Mechanism
• volar displacement of the distal radius (i.e. reverse Colles’ fracture)

Investigations
• X-ray: AP and lateral wrist

Treatment
• usually unstable and needs ORIF
• if patient is poor operative candidate, may attempt non-operative treatment
  • closed reduction with hematoma block (reduction opposite of Colles’)
  • long-arm cast in supination x 6 wk

Scaphoid Fracture

Epidemiology
• common in young men; not common in children or in patients beyond middle age
• most common carpal bone injured
• may be associated with other carpal or wrist injuries (e.g. Colles’ fracture)

Mechanism
• FOOSH: impaction of scaphoid on distal radius, most commonly resulting in a transverse fracture through the waist (65%), dorsal (10%), or proximal (25%) scaphoid

Clinical Features
• pain with resisted pronation
• tenderness in the anatomical “snuff box”, over scaphoid tubercle, and pain with long axis compression into scaphoid
• usually nondisplaced

Investigations
• X-ray: AP, lateral, scaphoid views with wrist extension and ulnar deviation
• ± CT or MRI
• bone scan rarely used
  • note: a fracture may not be radiologically evident up to 2 wk after acute injury, so if a patient complains of wrist pain and has anatomical snuff box tenderness but a negative x-ray, treat as if positive for a scaphoid fracture and repeat x-ray 2 wk later to rule out a fracture; if x-ray still negative, order CT or MRI

Treatment
• early treatment critical for improving outcomes
• non-operative
  • non-displaced (<1 mm displacement/<15° angulation): long arm thumb spica cast x 4 wk, then short arm cast until radiographic evidence of healing is seen (2-3 mo)
• operative
  • displaced: ORIF with headless/countersink compression screw is the mainstay treatment

Scaphoid Fracture Special Tests
• Tender snuff box: 100% sensitivity, but 29% specific, as it is also positive with many other injuries of radial aspect of wrist with FOOSH

Figure 21. Colles’ fracture and associated bony deformity

Figure 22. Normal wrist angles + wrist angles in Colles’ fracture
Note the relative shortening of the radius relative to the ulna on AP view in Colles’ fracture
Specific Complications (see General Fracture Complications, OR6)

- most common: nonunion/malunion (use bone graft from iliac crest or distal radius with fixation to heal)
- AVN of the proximal fragment
- delayed union (recommend surgical fixation)
- scaphoid nonunion advanced collapse (SNAC) – chronic nonunion leading to advanced collapse and arthritis of wrist

Prognosis

- proximal fifth fracture: AVN rate 100%; proximal third fracture: AVN rate 33%
- waist fractures have healing rates of 80-90%
- distal third fractures have healing rates close to 100%

Hand

- see Plastic Surgery, PL23

Spine

Fractures of the Spine

- see Neurosurgery, NS33

Cervical Spine

General Principles

- C1 (atlas): no vertebral body, no spinous process
- C2 (axis): odontoid = dens
- 7 cervical vertebrae; 8 cervical nerve roots
  - nerve root exits above vertebra (i.e. C4 nerve root exits above C4 vertebra), C8 nerve root exits below C7 vertebra
- radiculopathy = impingement of nerve root
- myelopathy = impingement of spinal cord

Special Testing

- compression test: pressure on head worsens radicular pain
- distraction test: traction on head relieves radicular symptoms
- Valsalva test: Valsalva maneuver increases intrathecal pressure and causes radicular pain
Table 13. Cervical Radiculopathy/Neuropathy

X-Rays for C-Spine
- AP spine: alignment
- AP odontoid: atlantoaxial articulation
- lateral
  - vertebral alignment: posterior vertebral bodies should be aligned (translation >3.5 mm is abnormal)
  - angulation: between adjacent vertebral bodies (>11° is abnormal)
  - disc or facet joint widening
  - anterior soft tissue space (at C3 should be ≤3 mm; at C4 should be ≤8-10 mm)
- oblique: evaluate pedicles and intervertebral foramen
- ± swimmer's view: lateral view with arm abducted 180° to evaluate C7-T1 junction if lateral view is inadequate
- ± lateral flexion/extension view: evaluate subluxation of cervical vertebrae

Differential Diagnosis of C-Spine Pain
- neck muscle strain, cervical spondylosis, cervical stenosis, RA (spondylitis), traumatic injury, whiplash, myofascial pain syndrome

C-SPINE INJURY
- see Neurosurgery, NS35

Thoracolumbar Spine

General Principles
- spinal cord terminates at conus medullaris (L1/2)
- individual nerve roots exit below pedicle of vertebra (i.e. L4 nerve root exits below L4 pedicle)

Special Tests
- straight leg raise: passive lifting of leg (30-70°) reproduces radicular symptoms of pain radiating down posterior/lateral leg to knee ± into foot
- Lasegue maneuver: dorsiflexion of foot during straight leg raise makes symptoms worse or if leg is less elevated, dorsiflexion will bring on symptoms
- femoral stretch test: with patient prone, flexing the knee of the affected side and passively extending the hip results in radicular symptoms of unilateral pain in anterior thigh

*D: Unreliable

Differential Diagnosis of Back Pain
1. mechanical or nerve compression (>90%)
   - degenerative (disc, facet, ligament)
   - peripheral nerve compression (disc herniation)
   - spinal stenosis (congenital, osteophyte, central disc)
   - cauda equina syndrome
2. others (<10%)
   - neoplastic (primary, metastatic, multiple myeloma)
   - infectious (osteomyelitis, TB)
   - metabolic (osteoporosis)
   - traumatic fracture (compression, distraction, translation, rotation)
   - spondyloarthropathies (ankylosing spondylitis)
   - referred (aorta, renal, ureter, pancreas)
DEGENERATIVE DISC DISEASE
- loss of vertebral disc height with age resulting in
  - bulging and tears of annulus fibrosus
  - change in alignment of facet joints
  - osteophyte formation

Mechanism
compression over time with age

Clinical Features
- axial back pain without radicular symptoms
- pain worse with axial loading and flexion
- negative straight leg raise

Investigations
- X-ray, MRI, provocative discography

Treatment
- non-operative
  - staying active with modified activity
  - back strengthening
  - NSAIDs
  - do not treat with opioids; no proven efficacy of spinal traction or manipulation
- operative – rarely indicated
  - decompression ± fusion
  - no difference in outcome between non-operative and surgical management at 2 yr

SPINAL STENOSIS
- narrowing of spinal canal <10 mm
- congenital (idiopathic, osteopetrosis, achondroplasia) or acquired (degenerative, iatrogenic – post spinal surgery, ankylosing spondylosis, Paget's disease, trauma)

Clinical Features
- ± bilateral back and leg pain
- neurogenic claudication
- ± motor weakness
- normal back flexion; difficulty with back extension (Kemp sign)
- positive straight leg raise, pain not worse with Valsalva

Investigations
- CT/MRI reveals narrowing of spinal canal but gold standard = CT myelogram

Treatment
- non-operative
  - vigorous physiotherapy (flexion exercises, stretch/strength exercises), NSAIDs, lumbar epidural steroids
- operative
  - indication: non-operative failure >6 mo
  - decompressive surgery

MECHANICAL BACK PAIN
- back pain NOT due to prolapsed disc or any other clearly defined pathology

Clinical Features
- dull backache aggravated by activity and prolonged standing
- morning stiffness
- no neurological signs

Treatment
- symptomatic (analgesics, physiotherapy)
- prognosis: symptoms may resolve in 4-6 wk, others become chronic

Cauda equina syndrome and ruptured aortic aneurysms are causes of low back pain that are considered surgical emergencies
LUMBAR DISC HERNIATION
- tear in annulus fibrosus allows protrusion of nucleus pulposus causing either a central, posterolateral, or lateral disc herniation, most commonly at L5-S1 > L4-5 > L3-4
- 3:1 male:female
- only 5% become symptomatic
- usually a history of flexion-type injury

Clinical Features
- back dominant pain (central herniation) or leg dominant pain (lateral herniation)
- tenderness between spinous processes at affected level
- muscle spasm ± loss of normal lumbar lordosis
- neurological disturbance is segmental and varies with level of central herniation
  - motor weakness (L4, L5, S1)
  - diminished reflexes (L4, S1)
  - diminished sensation (L4, L5, S1)
- positive straight leg raise
- positive contralateral SLR
- positive Lasegue and Bowstring sign
- cauda equina syndrome (present in 1-10%): surgical emergency

Investigations
- X-ray MRI, consider a post-void residual volume to check for urinary retention; post-void >100 mL should heighten suspicion for cauda equina syndrome

Treatment
- non-operative
  - symptomatic
    - extension protocol
    - NSAIDS
- operative
  - indication: progressive neurological deficit, failure of symptoms to resolve within 3 mo, or cauda equina syndrome due to central disc herniation
  - surgical discectomy
- prognosis
  - 90% of patients improve in 3 mo with non-operative treatment

SPONDYLOLYSIS

Definition
- defect in the pars interarticularis with no movement of the vertebral bodies

Mechanism
- trauma: gymnasts, weightlifters, backpackers, loggers, labourers
Clinical Features
- activity-related back pain, pain with unilateral extension (Michelis' test)

Investigations
- oblique X-ray: “collar” break in the “Scottie dog’s” neck
- bone scan
- CT scan

Treatment
- non-operative
  - activity restriction, brace, stretching exercise

ADULT ISTHMIC SPONDYLOLISTHESIS

Definition
- defect in pars interarticularis causing a forward translation or slippage of one vertebra on another, usually at L5-S1, less commonly at L4-5

Mechanism
- congenital (children), degenerative (adults), traumatic pathological, teratogenic

Clinical Features
- lower back pain radiating to buttocks relieved with sitting
- neurogenic claudication
- L5 radiculopathy
- Meyerding Classification (percentage of slip)

Investigations
- X-ray (AP, lateral, oblique flexion-extension views), MRI

Treatment
- non-operative
  - activity restriction, bracing, NSAIDS
- operative

Specific Complications
- may present as cauda equina syndrome due to roots being stretched over the edge of L5 or sacrum

Pelvis

Pelvic Fracture

Mechanism
- young: high energy trauma, either direct or by force transmitted longitudinally through the femur
- elderly: fall from standing height, low energy trauma
- lateral compression, vertical shear, or anteroposterior compression fractures

Clinical Features
- pain, inability to bear weight
- local swelling, tenderness
- deformity of lower extremity
- pelvic instability
Investigations
- X-ray: AP pelvis, inlet and outlet views, Judet views (obturator and iliac oblique for acetabular fracture)
  - 6 cardinal radiographic lines of the acetabulum: ilioischial line, iliopectineal line, teardrop, roof, poste ior rim, anterior rim
- CT scan useful for evaluating posterior pelvic injury and acetabular fracture
- assess genitourinary injury (rectal exam, vaginal exam, hematuria, blood at urethral meatus)
  - if involved, the fracture is considered an open fracture

Classification

<table>
<thead>

</tbody>
</table>

Treatment
- ABCDEs
- non-operative treatment: protected weight bearing
  - indication: stable fracture
- emergency management
  - IV fluids/blood
  - pelvic binder/sheeting
  - external fixation vs. emergent angiography/embolization
  - ± laparotomy (if FAST/DPL positive)
- operative treatment: ORIF
  - indications
    - unstable pelvic ring injury
    - disruption of anterior and posterior SI ligament
    - symphysis diastasis >2.5 cm
    - vertical instability of the posterior pelvis
    - open fracture

Specific Complications (see General Fracture Complications, OR6)
- hemorrhage (life-threatening)
- injury to rectum or urogenital structures
- obstetrical difficulties, sexual and voiding dysfunction
- persistent SI joint pain
- post-traumatic arthritis of the hip with acetabular fractures
- high risk of DVT/PE

Hip

Hip Dislocation

full trauma survey (see Emergency Medicine: Patient Assessment/Management, ER2)
- examine for neurovascular injury PRIOR to open or closed reduction
- reduce hip dislocations within 6 h to decrease risk of AVN of the femoral head
- hip precautions (no extreme hip flexion, adduction, internal or external rotation) for 6 wk post-reduction
- see Hip Dislocation Post-Total Hip Arthroplasty, OR29

ANTERIOR HIP DISLOCATION
- mechanism: posteriorly directed blow to knee with hip widely abducted
- clinical features: shortened, abducted, externally rotated limb
- treatment
  - closed reduction under conscious sedation/GA
  - post-reduction CT to assess joint congruity

Possible Radiological Findings
- Pubic rami fractures: superior/inferior
- Pubic symphysis diastasis: common in AP compression (N=5 mm)
- Sacral fractures: common in lateral compression
- SI joint diastasis: common in AP compression (N=1-4 mm)
- Disrupted anterior column (iliopectineal line) or posterior column (ilioischial line)
- “Teardrop” displacement: acetabular fracture
- iliac, ischial avulsion fractures
- Displacement of the major fragment: superior (VS), open book (APC), bucket handle (LC)
**POSTERIOR HIP DISLOCATION**

- most frequent type of hip dislocation
- mechanism: severe force to knee with hip flexed and adducted
  - e.g. knee into dashboard in MVC
- clinical features: shortened, adducted, internally rotated limb
- treatment
  - closed reduction under conscious sedation/GA only if no associated femoral neck fracture or ipsilateral displacement
  - ORIF if unstable, intra-articular fragments, or posterior wall fracture
  - post-reduction CT to assess joint congruity and fractures
  - if reduction is unstable, put in traction x 4-6 wk

**COMPLICATIONS FOR ALL HIP DISLOCATIONS**

- post-traumatic OA
- AVN of femoral head
- fracture of femoral head, neck, or shaft
- sciatic nerve palsy in 25% (10% permanent)
- HO
- thromboembolism - DVT/PE

**Hip Fracture**

**General Features**

- acute onset of hip pain
- unable to weight-bear
- shortened and externally-rotated leg
- painful ROM

**Table 19. Overview of Hip Fractures**

**Figure 34. Subcapital, intertrochanteric, and subtrochanteric hip fractures**

**Rochester Method to Reduce Posterior Dislocations**

- Patient lying supine with hip and knee flexed on injured side
- Surgeon stands on patient’s injured side
- Surgeon passes one arm under patient’s flexed knee, reaching to place that hand on patient’s other knee (thus supporting patient’s injured leg)
- With other hand, surgeon grasps patient’s ankle on injured side, applying traction, while assistant stabilizes pelvis
- Reduction via traction, internal rotation, then external rotation once femoral head clears acetabular rim

**X-Ray Features of Subcapital Hip Fractures**

- Disruption of Shenton’s line (a radiographic line drawn along the upper margin of the obturator foramen, extending along the inferomedial side of the femoral neck)
- Altered neck-shaft angle (normal is 120-130°)

**DVT Prophylaxis in Hip Fractures**

LMWH (i.e. enoxaparin 40 mg SC bid), fondaparinux, low dose heparin on admission, do not give <12 h before surgery

**AVN of Femoral Head**

- Distal to proximal blood supply along femoral neck to head (medial and lateral femoral circumflex arteries)
- Susceptible to AVN if blood supply disrupted

**Comparative Effectiveness of Pain Management Interventions for Hip Fracture: A Systematic Review**

**Study:** Randomized controlled trials (RCTs); nonrandomized controlled trials (non-RCTs); and cohort studies of pain management techniques in older adults after acute hip fracture.

**Conclusions:** Nerve blockade seems to be effective in reducing acute pain after hip fracture. Low-level evidence suggests that preoperative traction does not reduce acute pain. Evidence was insufficient on the benefits and harms of many other interventions.

Figure 35. Garden classification of femoral neck fractures

Arthritis of the Hip

Etiology
- OA, inflammatory arthritis, post-traumatic arthritis, late effects of congenital hip disorders, or septic arthritis

Clinical Features
- pain (groin, medial thigh) and stiffness aggravated by activity better with rest in OA
- RA: morning stiffness >1 h, multiple joint swelling, hand nodules
- decreased ROM (internal rotation is lost first)
- crepitus
- effusion
- ± fixed flexion contracture leading to apparent limb shortening (Thomas test)
- ± Trendelenburg sign

Investigations
- X-ray: weight-bearing views of affected joint
  - OA: joint space narrowing, subchondral sclerosis, subchondral cysts, osteophytes
  - RA: osteopenia, erosion, joint space narrowing, subchondral cysts
- blood work: ANA, RF

Treatment
- non-operative
  - weight reduction, activity modification, physiotherapy, analgesics, walking aids
- operative
  - indication advanced disease
  - realign = osteotomy; replace = arthroplasty; fuse = arthrodesis
  - complications with arthroplasty: component loosening dislocation, HO, thromboembolism, infection, neurovascular injury, limb length discrepancy
  - arthroplasty is standard of care in most patients with hip arthritis

Hip Dislocation Post-Total Hip Arthroplasty

- occurs in 1-4% of primary THA and 10-16% of revision THAs
- risk factors: neurological impairment, post-traumatic arthritis, revision surgery, substance abuse

Mechanism
- THA that is unstable when hip is flexed, adducted, and internally rotated, or extended and externally rotated (avoid flexing hip >90° or crossing legs for ~6 wk after surgery)

Investigations
- X-ray: AP pelvis, AP and lateral hip
Treatment
- non-operative
  - closed reduction: external abduction splint to prevent hip adduction (most often)
- operative
  - indication: 2 or more dislocations with evidence of polyethylene wear, malalignment, hardware failure
  - revision THA
  - conversion to hemiarthroplasty with a larger femoral head
  - resection arthroplasty is a last resort

Complications
- sciatic nerve palsy in 25% (10% permanent)
- HO
- infection

Femur

Femoral Diaphysis Fracture

Mechanism
- high energy trauma (MVC, fall from height, gunshot wound)
  - pathologic as a result of malignancy, osteoporosis, bisphosphonate use
  - in children, can result from low energy trauma (spiral fracture)

Clinical Features
- shortened, externally rotated leg (if fracture displaced)
- inability to weight-bear
- often open injury, always a Gustilo III (Table 5)
- Winquist and Hansen classification

Investigations
- X-ray: AP pelvis, AP/lateral hip, femur, knee

Treatment
- non-operative (uncommon)
  - indication: non-displaced femoral shaft fractures in co-morbid patients
  - long leg cast
- operative
  - ORIF with anterograde IM nail (most common) or retrograde IM nail; external fixator for unstable patients, open fractures, or highly vascular areas; or plate and screws for open growth plates within 24 h
  - early mobilization and strengthening

Complications
- blood loss
- fat embolism leading to ARDS
- extensive soft tissue damage
- ipsilateral hip dislocation/fracture (2-6%)
- nerve injury

Distal Femoral Fracture

- fractures from articular surface to 5 cm above metaphyseal flare

Mechanism
- direct high energy force or axial loading
- three types: extra articular, partial articular, complete articular

Clinical Features
- extreme pain
- knee effusion (hemarthrosis)
- neurovascular deficits can occur with displaced fracture

Investigations
- X-ray: AP, lateral
- CT, angiography if diminished pulses
Treatment
- non-operative (uncommon)
  - indication: non-displaced extra-articular fracture
  - hinged knee brace
- operative
  - indication: displaced fracture, intra-articular fracture, non-union
  - ORIF or retrograde IM nail if supracondylar and non-commminuted
  - early mobilization and strengthening

Specific Complications (see General Fracture Complications, OR6)
- femoral artery tear
- popliteal artery injury
- nerve injury
- extensive soft tissue injury
- angulation deformities

Knee

Evaluation of Knee

Common Complaints
- locking, instability, and swelling
  - torn meniscus/loose body in joint
- pseudo-locking: limited ROM without mechanical block
  - effusion, muscle spasm after injury, arthritis
- painful clicking (audible)
  - torn meniscus
- giving way: instability
  - cruciate ligament or meniscal tear, patellar dislocation

Special Tests of the Knee

- anterior and posterior drawer tests (Figure 39)
  - demonstrate ACL and PCL, respectively
    - knee flexed at 90°, foot immobilized, hamstrings released
    - if able to sublux tibia anteriorly (anterior drawer test), then ACL may be torn
    - if able to sublux tibia posteriorly (posterior drawer test), then PCL may be torn
    - anterior drawer test for ACL: 3.8 positive likelihood ratio, 0.30 negative likelihood ratio

- Lachman test
  - demonstrates torn ACL
  - hold knee in 10-20° flexion, stabilizing the femur
  - try to sublux tibia anteriorly on femur
  - similar to anterior drawer test, more reliable due to less muscular stabilization
  - for ACL: 25.0 positive likelihood ratio, 0.1 negative likelihood ratio

- pivot shift sign
  - demonstrates torn ACL
  - start with the knee in extension
  - internally rotate foot, slowly flex knee while palpating and applying a valgus force
  - if incompetent ACL, tibia will sublux anteriorly on femur at start of maneuver. During flexion, the tibia will reduce and externally rotate about the femur (the “pivot”)
  - reverse pivot shift (start in flexion, externally rotate, apply valgus and extend knee) suggests torn PCL
  - composite assessment for ACL: 25.0 positive likelihood ratio, 0.04 negative likelihood ratio
  - composite assessment for PCL: 21.0 positive likelihood ratio, 0.05 negative likelihood ratio

- posterior sag sign
  - demonstrates torn PCL
  - may give a false positive anterior drawer sign
  - flex knees and hips to 90°, hold ankles and knees
  - view from the lateral aspect
  - if one tibia sags posteriorly compared to the other, its PCL is torn

- collateral ligament stress test
  - palpate ligament for “opening” of joint space while testing
  - with knee in full extension, apply valgus force to test MCL, apply varus force to test LCL
  - repeat tests with knee in 20° flexion to relax joint capsule
  - opening in 20° flexion due to MCL damage only
  - opening in 20° of flexion and full extension is due to MCL, cruciate, and joint capsule damage

- Thessaly test
  - demonstrates meniscal tear
  - patient stands flat footed on one leg while the examiner provides his or her hands for balance. The patient then flexes the knee to 20° and rotates the femur on the tibia medially and laterally three times while maintaining the 20° flexion
Knee

- positive for a meniscal tear if the patient experiences medial or lateral joint line discomfort
- for medial meniscus: 29.67 positive likelihood ratio, 0.11 negative likelihood ratio
- for lateral meniscus: 23.0 positive likelihood ratio, 0.083 negative likelihood ratio

- tests for meniscal tear
  - joint line tenderness
    - joint line pain when palpated
    - palpate one side at a time and watch patient’s eyes
  - for meniscal tear: 0.9 positive likelihood ratio, 1.1 negative likelihood ratio
  - crouch compression test
  - joint line pain when squatting (anterior pain suggests patellofemoral pathology)
  - McMurray’s test (Figure 40)
    - with knee in flexion, palpate joint line for painful “pop/click”
    - lateral meniscus tear exam: internally rotate foot, varus stress, and extend knee
    - medial meniscus tear exam: externally rotate foot, valgus stress, and extend knee
  - for meniscal tear: 1.3 positive likelihood ratio, 0.8 negative likelihood ratio
  - composite assessment for meniscal tears: 2.7 positive likelihood ratio, 0.4 negative likelihood ratio

X-Rays
- AP standing, lateral
- skyline: tangential view with knees flexed at 45° to see patellofemoral joint
- 3-foot standing view: useful in evaluating leg length and varus/valgus alignment
- Ottawa Knee Rules (see Emergency Medicine, ER16)

Cruciate Ligament Tears

- ACL tear much more common than PCL tear

<table>
<thead>

Collateral Ligament Tears

**Mechanism**
- valgus force to knee = MCL tear
- varus force to knee = LCL tear

**Clinical Features**
- swelling/effusion
- tenderness above and below joint line medially (MCL) or laterally (LCL)
- joint laxity with varus or valgus force to knee
  - laxity with endpoint suggests partial tear
  - laxity with no endpoint suggests a complete tear
- test for other injuries (e.g. O’Donoghue’s unhappy triad), common peroneal nerve injury

**Investigations**
- x-ray: AP and lateral; MRI
Knee

Treatment
• non-operative
  ■ partial tear: immobilization x 2-4 wk with early ROM and strengthening
  ■ complete tear: immobilization at 30° flexion
• operative
  ■ indication: multiple ligamentous injuries
  ■ surgical repair of ligaments

Meniscal Tears
• medial tear much more common than lateral tear

Mechanism
• twisting force on knee when it is partially flexed (e.g. stepping down and turning)
  • requires moderate trauma in young person, but only mild trauma in elderly due to degeneration

Clinical Features
• immediate pain, difficulty weight-bearing, instability, and clicking
• increased pain with squatting and/or twisting
• effusion (hemarthrosis) with insidious onset (24-48 h after injury)
• joint line tenderness medially or laterally
• locking of knee (if portion of meniscus mechanically obstructing extension)

Investigations
• MRI, arthroscopy

Treatment
• non-operative
  ■ indication: not locked
  ■ ROM and strengthening (NSAIDs)
• operative
  ■ indication: locked or failed non-operative treatment
  ■ arthroscopic repair/partial meniscectomy

Quadriceps/Patellar Tendon Rupture

Mechanism
• sudden forceful contraction of quadriceps during an attempt to stop
  • more common in obese patients and those with pre-existing degenerative changes in tendon
    ■ DM, SLE, RA, steroid use, renal failure on dialysis

Clinical Features
• inability to extend knee or weight-bear
• possible audible “pop”
• patella in lower or higher position with palpable gap above or below patella, respectively
• may have an effusion

Investigations
• ask patient to straight leg raise (unable with complete rupture)
• knee X-ray to rule out patellar fracture, MRI to distinguish between complete and partial tears
• lateral view: patella alta with patellar tendon rupture, patella baja (infera) with quadriceps tendon rupture

Treatment
• non-operative
  ■ indication: incomplete tears with preserved extension of knee
  ■ immobilization in brace
• operative
  ■ indication: complete ruptures with loss of extensor mechanism
  ■ early surgical repair: better outcomes compared with delayed repair (>6 wk post-injury)
  ■ delayed repair complicated by quadriceps contracture, patella migration, and adhesions
Dislocated Knee

Mechanism
- high energy trauma
- by definition, caused by tears of multiple ligaments

Clinical Features
- classified by relation of tibia with respect to femur
  - anterior, posterior, lateral, medial, rotary
- knee instability
- effusion
- pain
- ischemic limb
- Schenck classification

Investigations
- X-ray: AP, lateral, skyline
- associated radiographic findings include tibial plateau fracture dislocations, proximal fibular fractures, and avulsion of fibular head
- ABI (abnormal if <0.9)
- arteriogram or CT angiogram if abnormal vascular exam (such as abnormal pedal pulses)

Treatment
- urgent closed reduction
  - complicated by interposed soft tissue
  - assessment of peroneal nerve, tibial artery, and ligamentous injuries
  - emergent operative repair if vascular injury, open fracture or dislocation, non-reducible dislocation, compartment syndrome
  - knee immobilization x 6-8 wk

Specific Complications
- high incidence of associated injuries
- popliteal artery tear
- peroneal nerve injury
- capsular tear
- chronic instability, stiffness, post-traumatic arthritis

Patella

Patellar Fracture

Mechanism
- direct blow to the patella: fall, MVC (dashboard)
- indirect trauma by sudden flexion of knee against contracted quadriceps

Clinical Features
- marked tenderness
- inability to extend knee or straight leg raise
- proximal displacement of patella
- patellar deformity
- ± effusion/hemarthrosis

Investigations
- X-rays: AP, lateral, skyline
  - do not confuse with bipartite patella: congenitally unfused ossification centres with smooth margins on X-ray at superolateral corner

Treatment
- non-operative
  - indication: non-displaced (step-off <2-3 mm and fracture gap <1-4 mm)
    - straight leg immobilization 1-4 wk with hinged knee brace, weight bearing as tolerated
    - progress in flexion after 2-3 wk
    - physiotherapy: quadriceps strengthening when pain has subsided
  - operative
    - indication: displaced (>2 mm), comminuted, disrupted extensor mechanism
    - ORIF, if comminuted may require partial/complete patellectomy
    - goal: restore extensor mechanism with maximal articular congruency

Complications
- Symptomatic wiring
- Loss of reduction
- Osteonecrosis (proximal fragment)
- Hardware failure
- Knee stiffness
- Nonunion
- Infection
Patellar Dislocation

Mechanism
- usually a non-contact twisting injury
- lateral displacement of patella after contraction of quadriceps at the start of knee flexion in an almost straight knee joint
- direct blow, e.g. knee/helmet to knee collision

Risk Factors
- young, female
- obesity
- high-riding patella (patella alta)
- genu valgus
- Q-angle (quadriceps angle) ≥20°
- shallow intercondylar groove
- weak vastus medialis
- tight lateral retinaculum
- ligamentous laxity (Ehlers-Danlos)

Clinical Features
- knee catches or gives way with walking
- severe pain, tenderness anteromedially from rupture of capsule
- weak knee extension or inability to extend leg unless patella reduced
- positive patellar apprehension test
- often recurrent, self-reducing
- concomitant MCL injury
- increased Q-angle
- J-sign

Investigations
- X-rays: AP, lateral, skyline view of patella
- check for fracture of medial patella (most common) and lateral femoral condyle

Treatment
- non-operative first
  - NSAIDs, activity modification, and physical therapy
  - short-term immobilization for comfort, then 6 wk controlled motion
  - progressive weight bearing and isometric quadriceps strengthening
- operative
  - indication: if recurrent or if loose bodies present
  - surgical tightening of medial capsule and release of lateral retinaculum, possible tibial tuberosity transfer, or proximal tibial osteotomy

Patellofemoral Syndrome (Chondromalacia Patellae)

- syndrome of anterior knee pain associated with idiopathic articular changes of patella

Risk Factors
- malalignment causing patellar maltracking (Q angle ≥20°, genu valgus)
- post-trauma
- deformity of patella or femoral groove
- recurrent patellar dislocation, ligamentous laxity
- excessive knee strain (athletes)

Mechanism
- softening, erosion, and fragmentation of articular cartilage, predominantly medial aspect of patella
- commonly seen in active young females

Clinical Features
- deep, aching anterior knee pain
  - exacerbated by prolonged sitting (theatre sign), strenuous athletic activities, stair climbing, squatting, or kneeling
- insidious onset and vague in nature
- sensation of instability, pseudolocking
- pain with extension against resistance through terminal 30–40°
- pain with compression of patella with knee ROM or resisted knee extension
- swelling rare, minimal if present
- palpable crepitus

Investigations
- X-ray: AP, lateral, skyline – may find chondrosis, lateral patellar tilt, patella alta/baja, or shallow sulcus
- CT-scan
- MRI – best to assess articular cartilage
Treatment
- non-operative
  - continue non-impact activities; rest and rehabilitation
  - NSAIDs
  - physiotherapy: vastus medialis and core strengthening
- operative
  - indication: failed non-operative treatment
  - tibial tubercle elevation
  - arthroscopic shaving/debridement
  - lateral release of retinaculum

Tibia Plateau Fracture

Mechanism
- varus/valgus load ± axial loading (e.g. fall from height)
- femoral condyles driven into proximal tibia
- can result from minor trauma in those with osteoporosis

Clinical Features
- frequency: lateral > bicondylar > medial
- medial fractures require higher energy – often have concomitant vascular injuries
- knee effusion
- inability to bear weight
- swelling
- associated with compartment syndrome, ACL injury, and meniscal tears
- Schatzker classification

Investigations
- X-ray: AP, lateral, oblique
- CT: pre-operative planning, identify articular depression and comminution
- ABI if any differences in pulses between extremities

Treatment

<table>
<thead>
<tr>
<th>Approach #1 (based on amount of depression seen on x-ray)</th>
<th>Non-operative indication (if depression on x-ray is &lt;3 mm): straight leg immobilization x 4-6 wk with progressive ROM weight bearing</th>
<th>Operative indication (if depression is &gt;3 mm): ORIF often requiring bone grafting to elevate depressed fragment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Approach #2 (based on varus/valgus instability)</td>

<td>Operative indication (if significant varus/valgus instability [&gt;15°]): ORIF often requiring bone grafting to elevate depressed fragment</td>
</tr>
</tbody>
</table>

Specific Complications (see General Fracture Complications, OR6)
- ligamentous injuries
- meniscal lesions
- AVN
- infection
- OA

Tibial Shaft Fracture
- most common long bone fracture and open fracture

Mechanism
- low energy pattern: torsional injury
- high energy: including MVC, falls, sporting injuries

Clinical Features
- pain, inability to weight bear
- open vs. closed
- neurovascular compromise

Investigations
- X-ray: AP lateral
  - full length, plus knee and ankle

Schatzker Classification

</tbody>
</table>

Figure 44. Tibial shaft fracture treated with IM nail and screws
Treatment
• non-operative
  ■ indication: closed and minimally displaced or adequate closed reduction
  • long leg cast x 8-12 wk, functional brace after
• operative
  ■ indication: displaced or open
  • if displaced and closed: ORIF with IM nail, plate and screws, or external fixator
  • if open: antibiotics, I&D, external fixation or IM nail, and vascularized coverage of soft tissue defects

Specific Complications (see General Fracture Complications, OR6)
• high incidence of neurovascular injury and compartment syndrome
• poor soft tissue coverage (critical to outcome)

Ankle

Evaluation of Ankle and Foot Complaints

Special Tests
• anterior drawer: examiner attempts to displace the foot anteriorly against a fixed tibia
• talar tilt: foot is stressed in inversion and angle of talar rotation is evaluated by X-ray

X-Ray
• AP, lateral
• mortise view: ankle at 15° of internal rotation
  • gives true view of ankle joint
  • joint space should be symmetric with no talar tilt
• Ottawa Ankle Rules should guide X-ray use (see Emergency Medicine, ER17); nearly 100% sensitivity
• ± CT to better characterize fractures

Ankle Fracture

Mechanism
• pattern of fracture depends on the position of the ankle when trauma occurs
• generally involves
  ■ ipsilateral ligamentous tears or transverse bony avulsion
  ■ contralateral shear fractures (oblique or spiral)
• classification systems
  ■ Danis-Weber
  ■ Lauge-Hansen: based on foot's position and motion relative to leg

Treatment
• non-operative
  ■ indication: non-displaced, no history of dislocation
  • below knee cast, NWB
• operative
  ■ indications
    • any fracture-dislocation: restore vascularity, minimize articular injury, reduce pain and skin pressure
    • most of type B, and all of type C
    • talar malleolar (medial, posterior, lateral) fractures
    • talar tilt >10°
    • medial clear space on X-ray greater than superior clear space
    • open fracture/open joint injury
  • ORIF

Complications
• high incidence of post-traumatic arthritis

Tibial shaft fractures have high incidence of compartment syndrome and are often associated with soft tissue injuries

Ottawa Ankle Rules (see Emergency Medicine, ER17)
X-rays are only required if:
  Pain in the malleolar zone AND bony tenderness over the distal 6 cm of the posterior aspect of the tibia or tip of the medial or lateral malleolus OR inability to weight bear both immediately after injury and in the ER

Figure 45 Ring principle of the ankle and Danis-Weber classification
Ankle Ligamentous Injuries

- see Figure 46 for ankle ligaments

Medial Ligament Complex (deltoid ligament)
- eversion injury
- usually avulses medial or posterior malleolus and strains syndesmosis

Lateral Ligament Complex (Anterior Talofibular, Calcaneofibular, Posterior Talofibular)
- inversion injury, >90% of all ankle sprains
- ATF most commonly and severely injured if ankle is plantarflexed
- swelling and tenderness anterior to lateral malleolus
- +++ ecchymosis
- positive ankle anterior drawer
- may have significant medial talar tilt on inversion stress X-ray

Treatment
- non-operative
  - microscopic tear (Grade I)
    - rest, ice, compression, elevation
  - macroscopic tear (Grade II)
    - strap ankle in dorsiflexion and eversion x 4-6 wk
    - physiotherapy: strengthening and proprioceptive retraining
  - complete tear (Grade III)
    - below knee walking cast x 4-6 wk
    - physiotherapy: strengthening and proprioceptive retraining
- surgical intervention may be required if chronic symptomatic instability develops

Foot

Talar Fracture

Mechanism
- axial loading or hyperdorsiflexion (MVC, fall from height)
- 60% of talus covered by articular cartilage
- talar neck is most common fracture of talus (50%)
- tenuous blood supply runs distal to proximal along talar neck
- high risk of AVN with displaced fractures

Investigations
- X-ray: AP, lateral, Canale view
- CT to better characterize fracture
- MRI can clearly define extent of AVN

Treatment
- non-operative
  - indication: non-displaced
    - NWB, below-knee cast x 6 wk
  - operative
    - indication: displaced
    - ORIF (high rate of nonunion, AVN)
    - neck fracture: ORIF

Calcaneal Fracture

- most common tarsal fracture

Mechanism
- high energy, axial loading: fall from height onto heels
- 10% of fractures associated with compression fractures of thoracic or lumbar spine (rule out spine injury)
- 75% are intra-articular and 10% are bilateral

Clinical Features
- marked swelling, bruising on heel/sole
- wider, shortened, flatter heel when viewed from behind
- varus heel

With a history of significant trauma from axial loading of lower limb, always consider spinal injuries, femoral neck, tibial plateau, and talar/ calcaneal fractures

Calcaneal Fracture

- most common tarsal fracture

Mechanism
- high energy, axial loading: fall from height onto heels
- 10% of fractures associated with compression fractures of thoracic or lumbar spine (rule out spine injury)
- 75% are intra-articular and 10% are bilateral

Clinical Features
- marked swelling, bruising on heel/sole
- wider, shortened, flatter heel when viewed from behind
- varus heel

Figure 46. Ankle ligament complexes
Investigations
• X-rays: AP, lateral, oblique foot (mandatory views); can also assess with Broden view, Harris view, or AP ankle.
• loss of Bohler’s angle
• CT: gold standard, assess intra-articular extension

Treatment
• closed vs. open reduction is controversial
• NWB cast x 3 mo with early ROM and strengthening

Achilles Tendonitis

Mechanism
• chronic inflammation from activity or poor-fitting footwear
• may also develop heel bumps (retrocalcaneobursitis or Haglund deformity)

Clinical Features
• pain, stiffness, and crepitus with ROM
• thickened tendon, palpable bump

Investigations
• X-ray: lateral, evaluate bone spur and calcification; U/S, MRI (to assess degenerative change)

Treatment
• non-operative
  • rest, NSAIDs, shoe wear modification (orthotics, open back shoes)
  • heel sleeves and pads are mainstay of non-operative treatment
  • gentle gastrocnemius-soleus stretching, eccentric training with physical therapy, deep tissue calf massage
  • shockwave therapy in chronic tendonitis
  • DO NOT inject steroids (risk of tendon rupture)

Achilles Tendon Rupture

Mechanism
• loading activity, stop-and-go sports (e.g. squash, tennis, basketball)
• secondary to chronic tendonitis, steroid injection

Clinical Features
• audible pop, sudden pain with push-off movement
• pain or inability to plantarflex
• palpable gap
• apprehensive toe off when walking
• weak plantarflexion strength
• Thompson test: with patient prone, squeeze calf, normal response is plantar flexion
  • no passive plantarflexion = positive test = ruptured tendon

Investigations
• X-ray (to rule out other pathology), U/S or MRI (for partial vs. complete ruptures)

Treatment
• non-operative
  • indication: low athletic demand or elderly
  • cast foot in plantar flexion (to relax tendon) x 8-12 wk
• operative
  • indication: high athletic demand
  • surgical repair, then cast as above x 6-8 wk

Plantar Fasciitis (Heel Spur Syndrome)

Definition
• inflammation of plantar aponeurosis at calcaneal origin
• common in athletes (especially runners, dancers)
• also associated with obesity, DM, seronegative and seropositive arthritis

Mechanism
• repetitive strain injury causing microtears and inflammation of plantar fascia

Figure 47. X-ray of bony heel spur
Clinical Features

• insidious onset of heel pain, pain when getting out of bed, and stiffness
• intense pain when walking from rest that subsides as patient continues to walk, worse at end of day with prolonged standing
• swelling, tenderness over sole
• greatest at medial calcaneal tubercle and 1-2 cm distal along plantar fascia
  pain with toe dorsiflexion (stretches fascia)

Investigations

• plain radiographs to rule out fractures
• often see bony exostoses (heel spurs) at insertion of fascia into medial calcaneal tubercle
• spur is secondary to inflammation, not the cause of pain

Treatment

• non-operative
  ■ pain control and stretching programs are first-line
  ■ rest, ice, NSAIDs, steroid injection
  ■ physiotherapy: Achilles tendon and plantar fascia stretching, extracorporeal shockwave therapy
  ■ orthotics with heel cup – to counteract pronation and disperse heel strike forces
• operative
  ■ indication: failed non-operative treatment
  ■ endoscopic surgical release of fascia
  ■ spur removal is not required

Bunions (Hallux Valgus)

Definition

• bony deformity characterized by medial displacement of first metatarsal and lateral deviation of hallux

Mechanism

• valgus alignment on 1st MTP (hallux valgus) causes eccentric pull of extensor and intrinsic muscles
• many associated deformities in foot from altered mechanics
• reactive exostosis forms with thickening of the skin, creating a bunion
• most often associated with poor-fitting footwear (high heel and narrow toe box)
• can be hereditary (70% have family history)
• 10x more frequent in women

Clinical Features

• painful bursa over medial eminence of 1st MT head
• pronation (rotation inward) of great toe
• numbness over medial aspect of great toe

Investigations

• X-ray: standing AP/lateral/sesamoid view, NWB oblique

Treatment

• indications: painful corn or bunion, overriding 2nd toe
• non-operative (first-line)
  ■ properly fitted shoes (low heel) and toe spacer
• operative: goal is to restore normal anatomy, not cosmetic reasons alone
  ■ osteotomy with realignment of 1st MTP joint (Chevron Procedure)
  ■ arthrodesis

Metatarsal Fracture

• as with the hand, 1st, 4th, 5th MT are relatively mobile while the 2nd and 3rd are fixed
• use Ottawa Foot Rules to determine need for x-ray

Table 22. Types of Metatarsal Fractures

Pediatric Orthopedics

Fractures in Children

- type of fracture
  - thicker, more active periosteum results in pediatric-specific fractures: greenstick (one cortex), torus (i.e. ‘buckle’, impacted cortex) and plastic (bowing)
  - distal radius fracture most common in children (phalanges second), the majority are treated with closed reduction and casting
  - adults fracture through both cortices
- epiphyseal growth plate
  - weaker part of bone, susceptible to fractures
  - plate often mistaken for fracture on x-ray and vice versa (X-ray opposite limb for comparison), especially in elbow
  - tensile strength of bone < ligaments in children, therefore clinician must be confident that fracture and/or growth plate injury have been ruled out before diagnosing a sprain
  - intra-articular fractures have worse consequences in children because they usually involve the growth plate
- anatomic reduction
  - gold standard with adults
  - may cause limb length discrepancy in children (overgrowth)
  - accept greater angular deformity in children (remodelling minimizes deformity)
- time to heal
  - shorter in children
  - always be aware of the possibility of child abuse
  - make sure stated mechanism compatible with injury
  - high index of suspicion with fractures in non-ambulating children (<1 yr); look for other signs, including X-ray evidence of healing fractures at different sites and different stages of healing
  - common suspicious fractures in children: metaphyseal corner fracture (hallmark of non-accidental trauma), femur fracture < 1 yo, humeral shaft < 3 yo, sternal fractures, posterior rib fractures, spinous process fractures

Stress Fractures

Mechanism
- insufficiency fracture
  - stress applied to a weak or structurally deficient bone
- fatigue fracture
  - repetitive, excessive force applied to normal bone
- most common in adolescent athletes
- tibia is most common site

Diagnosis
- localized pain and tenderness over the involved bone
- plain films may not show fracture for 2 wk
- bone scan positive in 12-15 d

Treatment
- rest from strenuous activities to allow remodelling (can take several months)

Epiphyseal Injury

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>I (Straight through; Stable)</td>
<td>Transverse through growth plate</td>
<td>Closed reduction and cast immobilization (except SCFE – ORIF); heals well, 95% do not affect growth</td>
</tr>
<tr>
<td>II (Above)</td>
<td>Through metaphysis and along growth plate</td>
<td>Closed reduction and cast if anatomic; otherwise ORIF</td>
</tr>
<tr>
<td>III (Low)*</td>
<td>Through epiphysis to plate and along growth plate</td>
<td>Anatomic reduction by ORIF to prevent growth arrest, avoid fixation across growth plate</td>
</tr>
<tr>
<td>IV (Through and through)*</td>
<td>Through epiphysis and metaphysis</td>
<td>Closed reduction and cast if anatomic; otherwise ORIF</td>
</tr>
<tr>
<td>V (Ram)*</td>
<td>Crush injury of growth plate</td>
<td>High incidence of growth arrest; no specific treatment</td>
</tr>
</tbody>
</table>

* Types II – IV are more likely to cause growth arrest and progressive deformity
Slipped Capital Femoral Epiphysis

Definition
- type I Salter-Harris epiphyseal injury at proximal hip
- most common adolescent hip disorder, peak incidence at pubertal growth spurt
- risk factors: male, obese (#1 factor), hypothyroid (risk of bilateral involvement)

Etiology
- multifactorial
  - genetic: autosomal dominant, black children at highest risk
  - cartilaginous physis hypertrophies too rapidly under growth hormone effects
  - sex hormone secretion, which stabilizes physis, has not yet begun
  - overweight: mechanical stress
  - trauma: causes acute slip

Clinical Features
- acute: sudden, severe pain with limp
- chronic (typically): groin and anterior thigh pain, may present with knee pain
  - positive Trendelenburg sign on affected side, due to weakened gluteal muscles
  - tender over joint capsule
  - restricted internal rotation, abduction, flexion
  - Whitman’s sign: obligatory external rotation during passive flexion of hip
  - Loder classification: stable vs. unstable (provides prognostic information)
    - unstable means patient cannot ambulate even with crutches

Investigations
- X-ray: AP, frog-leg, lateral radiographs both hips
  - posterior and medial slip of epiphysis
  - disruption of Klein’s line
  - AP view may be normal or show widened/lucent growth plate compared with opposite side

Treatment
- operative
  - mild/moderate slip: stabilize physis with pins in current position
  - severe slip: ORIF or pin physis without reduction and osteotomy after epiphyseal fusion

Complications
- AVN (roughly half of unstable hips), chondrolysis (loss of articular cartilage, resulting in narrowing of joint space), pin penetration, premature OA, loss of ROM

Developmental Dysplasia of the Hip

Definition
- abnormal development of hip, resulting in dysplasia and subluxation/dislocation of hip
- most common orthopedic disorder in newborns

Etiology
- due to ligamentous laxity, muscular underdevelopment, and abnormal shallow slope of acetabular roof
- spectrum of conditions
  - dislocated femoral head completely out of acetabulum
  - dislocatable head in socket
  - head subluxates out of joint when provoked
  - dysplastic acetabulum, more shallow and more vertical than normal
- if painful, suspect septic dislocation (normally painless)

Physical Exam
- diagnosis is clinical
  - limited abduction of the flexed hip (<60°)
  - affected leg shortening results in asymmetry in skin folds and gluteal muscles, wide perineum
  - Barlow’s test (checks if hips are dislocatable (Figure 51))
    - flex hips and knees to 90° and grasp thigh
    - fully adduct hips, push posteriorly to try to dislocate hips
  - Ortolani’s test (checks if hips are dislocated (Figure 51))
    - initial position as above but try to reduce hip with fingertips during abduction
    - positive test: palpable clunk is felt (not heard) if hip is reduced
  - Galeazzi’s sign
    - knees at unequal heights when hips and knees flexed
    - dislocated hip on side of lower knee
    - difficult test if child <1 yr
    - Trendelenburg test and gait useful if older (>2 yr)
Pediatric Orthopedics

Investigations
- U/S in first few months to view cartilage (bone is not calcified in newborns until 4-6 mo)
- follow-up radiograph after 3 mo
- X-ray signs (at 4-6 mo): false acetabulum, acetabular index >25°, broken Shenton's line, femoral neck above Hilgenreiner's line, ossification centre outside of inner lower quadrant (quadrants formed by intersection of Hilgenreiner's and Perkin's lines)

Treatment
- 0-6 mo: reduce hip using Pavlik harness to maintain abduction and flexion
- 6-18 mo: reduction under GA, hip spica cast x 2-3 mo (if Pavlik harness fails)
- >18 mo: open reduction; pelvic and/or femoral osteotomy

Complications
- redislocation, inadequate reduction, stiffness
- AVN of femoral head

Legg-Calvé-Perthes Disease (Coxa Plana)

Definition
- idiopathic AVN of femoral head, presents at 4-8 yr of age
- 12% bilateral, M>F = 5:1, 1/1,200
- associations
  - family history
  - low birth weight
  - abnormal pregnancy/delivery
  - ADHD in 33% of cases, delayed bone age in 89%
  - second-hand smoke exposure
  - Asian, Inuit, Central European
- key features
  - AVN of proximal femoral epiphysis, abnormal growth of the physis, and eventual remodelling of regenerated bone

Clinical Features
- child with antalgic or Trendelenburg gait ± pain
- intermittent knee, hip, groin, or thigh pain
- flexion contracture (stiff hip): decreased internal rotation and abduction of hip
- limb length discrepancy (late)

Investigations
- X-ray: AP pelvis, frog leg laterals
- may be negative early (if high index of suspicion, move to bone scan or MRI)
- eventually, characteristic collapse of femoral head (diagnostic)

Treatment
- goal is to preserve ROM and keep femoral head contained in acetabulum
- non-operative
  - physiotherapy: ROM exercises
  - brace in flexion and abduction x 2-3 yr (controversial)
- operative
  - femoral or pelvic osteotomy (>8 yr of age or severe)
    - prognosis better in males, <6 yr, <50% of femoral head involved, abduction >30°
  - 60% of involved hips do not require operative intervention
  - natural history is early onset OA and decreased ROM

Osgood-Schlatter Disease

Definition
- inflammation of patellar ligament at insertion point on tibial tuberosity
- M>F
- age of onset: boys 12-15 yr; girls 8-12 yr

Mechanism
- repetitive tensile stress on insertion of patellar tendon over the tibial tuberosity causes minor avulsion at the site and subsequent inflammatory reaction (tibial tubercle apophysitis)

Clinical Features
- tender lump over tibial tuberosity
- pain on resisted leg extension
- anterior knee pain exacerbated by jumping or kneeling, relieved by rest

Investigations
- X-ray lateral knee: fragmentation of the tibial tubercle, ± ossicles in patellar tendon

5 Fs that Predispose to Developmental Dysplasia of the Hip
- Family history
- Female
- Frank breech
- First born
- Left hip

Figure 52. Pelvic x-ray and reference lines and angles for assessment of DDH
- Triradiate Cartilage
  - y-shaped epiphyseal plate at junction of ilium, ischium and pubis
- Hilgenreiner’s Line
  - Line running between triradiate cartilages
- Perkin’s Line
  - Line through lateral margin of acetabulum, perpendicular to Hilgenreiner’s Line
- Shenton’s Line
  - Arced line along inferior border of femoral neck and superior margin of obturator foramen
- Acetabular Index
  - Angle between Hilgenreiner’s Line and line from triradiate cartilage to point on lateral margin of acetabulum

Most common in adolescent athletes, especially jumping/sprinting sports
Children diagnosed with coxa plana <6 yr of age have improved prognosis
Treatment
- benign, self limited condition, does not resolve until growth halts
- non-operative (majority)
  - may restrict activities such as basketball or cycling
  - NSAIDs, rest, flexibility, isometric strengthening exercises
  - casting if symptoms do not resolve with conservative management
- operative: ossicle excision in refractory cases (patient is skeletally mature with persistent symptoms)

Congenital Talipes Equinovarus (Club Foot)

Definition
- congenital foot deformity
- muscle contractures resulting in CAVE deformity
- bony deformity: talar neck medial and plantar deviated; varus calcaneus and rotated medially around talus; navicular and cuboid medially displaced
- 1-2/1,000 newborns, 50% bilateral, occurrence M>F, severity F>M

Etiology
- intrinsic causes (neurologic, muscular, or connective tissue diseases) vs. extrinsic (intrauterine growth restriction); may be idiopathic, neurogenic, or syndrome-associated
- fixed deformity

Physical Exam
- examine hips for associated DDH
- examine knees for deformity
- examine back for dysraphism (unfused vertebral bodies)

Treatment
- largely non-operative via Ponseti Technique (serial manipulation and casting)
  - correct deformities in CAVE order
    - change strapping/cast q1-2wk
    - surgical release in refractory case (rare)
      - delayed until 3-4 mo of age
  - 3 yr recurrence rate = 5-10%
  - mild recurrence common; affected foot is permanently smaller/stiffer than normal foot with calf muscle atrophy

Scoliosis

Definition
- lateral curvature of spine with vertebral rotation
- age: 10-14 yr
- more frequent and more severe in females

Etiology
- idiopathic: most common (90%)
- congenital: vertebrae fail to form or segment
- neuromuscular: UMN or LMN lesion, myopathy
- postural: leg length discrepancy, muscle spasm
- other: osteochondrodystrophies, neoplastic, traumatic

Clinical Features
- ± back pain
- primary curve where several vertebrae affected
- secondary curves above and below fixed 1° curve to try and maintain normal position of head and pelvis
- asymmetric shoulder height when bent forward
- Adam’s test: rib hump when bent forward
- prominent scapulae, creased flank, asymmetric pelvis
- associated posterior midline skin lesions in neuromuscular scolioses
  - café-au-lait spots, dimples, neurofibromas
  - axillary freckling, hemangiomas, hair patches
- associated pes cavus or leg atrophy
- apparent leg length discrepancy

Investigations
- X-ray: 3-foot standing, AP, lateral
  - measure curvature: Cobb angle
  - may have associated kyphosis
**Bone Tumours**

- primary bone tumours are rare after 3rd decade
- metastases to bone are relatively common after 3rd decade

**Clinical Features**

- malignant (primary or metastasis): local pain and swelling (wk – mo), worse on exertion and at night, ± soft tissue mass
- benign: usually asymptomatic
- minor trauma often initiating event that calls attention to lesion

**Table 24. Distinguishing Benign from Malignant Bone Lesions on X-Ray**

</tr>
</tbody>
</table>

*Adapted from: Buckhoult RW, Heckman JD. Rockwood & Green’s Fractures in Adults. Volume 1. Philadelphia: Lippincott Williams & Wilkins, 2001. p558*

**Diagnosis**

- malignancy is suggested by rapid growth, warmth, tenderness, lack of sharp definition
- staging should include
  - blood work including liver enzymes
  - CT chest
  - bone scan
  - bone biopsy
    - should be referred to specialized centre prior to biopsy
    - classified into benign, benign aggressive, and malignant
  - MRI of affected bone

**Benign Active Bone Tumours**

**BONE-FORMING TUMOURS**

**Osteoid Osteoma**

- bone tumour arising from osteoblasts
- peak incidence in 2nd and 3rd decades, M:F = 2:1
- proximal femur and tibia diaphysis most common locations
- not known to metastasize
- radiographic findings: small, round radiolucent nidus (<1.5 cm) surrounded by dense sclerotic bone ("bull’s eye")
- symptoms: produces severe intermittent pain from prostaglandin secretion and COX1/2 expression, mostly at night (diurnal prostaglandin production), thus is characteristically relieved by NSAIDs
- treatment: NSAIDs for night pain; surgical resection of nidus

**FIBROUS LESIONS**

**Fibrous Cortical Defect**

- or non-ossifying fibroma; fibrous bone lesion
- most common benign bone tumour in children, typically asymptomatic and an incidental finding
- occur in as many as 35% of children, peak incidence between 2-25 yr old; higher prevalence in males
- femur and proximal tibia most common locations, 50% of patients have multiple defects that are usually bilateral, symmetrical
- radiographic findings: diagnostic, metaphyseal eccentric 'bubbly' lytic lesion near physis; thin, smooth/lobulated, well-defined sclerotic margin
- treatment: most lesions resolve spontaneously
Osteochondroma
- cartilage capped bony tumour
- 2nd and 3rd decades, M:F = 1.8:1
- most common of all benign bone tumours – 45%
- 2 types: sessile (broad based and increased risk of malignant degeneration) vs. pedunculated (narrow stalk)
- metaphysis of long bone near tendon attachment sites (usually distal femur, proximal tibia, or proximal humerus)
- radiographic findings: cartilage-capped bony spur on surface of bone (“mushroom” on x-ray)
- may be multiple (hereditary, autosomal dominant form) – higher risk of malignant change
- generally very slow growing and asymptomatic unless impinging on neurovascular structure (‘painless mass’)
  - growth usually ceases when skeletal maturity is reached
- malignant degeneration occurs in 1-2% (becomes painful or rapidly grows)
- treatment: typically observation; surgical excision if symptomatic

Enchondroma
- hyaline cartilage tumour; majority asymptomatic, presenting as incidental finding or pathological fracture
- 2nd and 3rd decades
- 60% occur in the small tubular bones of the hand and foot; others in femur (20% - Figure 56), humerus, ribs
- benign cartilaginous growth, an abnormality of chondroblasts, develops in medullary cavity
  - single/multiple enlarged rarefied areas in tubular bones
  - lytic lesion with sharp margination and irregular central calcification (stippled/punctate/popcorn appearance)
  - malignant degeneration to chondrosarcoma occurs in 1-2% (pain in absence of pathologic fracture is an important clue)
  - not known to metastasize
  - treatment: observation with serial x-rays; surgical curettage if symptomatic or lesion grows

CYSTIC LESIONS

Unicameral/Solitary Bone Cyst
- most common cystic lesion; serous fluid-filled lesion
- children and young adults, peak incidence during first 2 decades, M:F = 2:1
- proximal humerus and femur most common
- symptoms: asymptomatic, or local pain; complete pathological fracture (50% of presentations) or incidental detection
- radiographic findings: lytic translucent area on metaphyseal side of growth plate, cortex thinned/expanded; well-defined lesion
- treatment: aspiration followed by steroid injection; curettage ± bone graft indicated if re-fracture likely

Benign Aggressive Bone Tumours

Giant Cell Tumours/Aneurysmal Bone Cyst/Osteoblastoma
- affects patients of skeletal maturity, peak 3rd decade
- osteoblastoma: found in the distal femur, proximal tibia, distal radius, sacrum, tarsal bones, spine
- giant cell tumour: pulmonary metastases in 3%
- aneurysmal bone cysts (Figure 57): either solid with fibrous/granular tissue, or blood-filled
- radiographic findings
  - giant cell tumour: eccentric lytic lesions in epiphyses adjacent to subchondral bone; may break through cortex; T2 MRI enhances fluid within lesion (hyper-intense signal)
  - aneurysmal bone cyst: expanded with honeycomb shape
  - osteoblastoma: often nonspecific; calcified central nidus (>2 cm) with radiolucent halo and sclerosis
- symptoms: local tenderness and swelling, pain may be progressive (giant cell tumours), ± symptoms of nerve root compression (osteoblastoma)
- 15% recur within 2 yr of surgery

Treatment
- intralesional curettage ± bone graft or cement
- wide local excision of expendable bones
Malignant Bone Tumours

Table 25. Most Common Malignant Tumour Types for Age

</table>

Osteosarcoma
- malignant bone tumour
- most frequently diagnosed in 2nd decade of life (60%), 2nd most common primary malignancy in adults
- history of Paget’s disease (elderly patients), previous radiation treatment
- predilection for sites of rapid growth: distal femur (45% - Figure 58), proximal tibia (20%), and proximal humerus (15%)
  - invasive, variable histology; frequent metastases without treatment (lung most common)
- painful symptoms: progressive pain, night pain, poorly defined swelling, decreased ROM
- radiographic findings
  - characteristic periosteal reaction: Codman’s triangle (Figure 55) or “sunburst” spicule formation (tumour extension into periosteum)
  - destructive lesion in metaphysis may cross epiphyseal plate
- management: complete resection (limb salvage, rarely amputation), neo-adjuvant chemo; bone scan – rule out skeletal metastases, CT chest – rule out pulmonary metastases
- prognosis: 70% survival (high-grade); 90% survival (low-grade)

Chondrosarcoma
- malignant chondrogenic tumour
- primary (2/3 cases)
  - previous normal bone, patient >40 yr; expands into cortex to cause pain, pathological fracture
- secondary (1/3 cases)
  - malignant degeneration of pre-existing cartilage tumour such as enchondroma or osteochondroma
  - age range 25-45 yr, better prognosis than primary chondrosarcoma
- symptoms: progressive pain, uncommonly palpable mass
- radiographic findings: in medullary cavity, irregular “popcorn” calcification (Figure 59)
- treatment: unresponsive to chemotherapy, treat with aggressive surgical resection + reconstruction; regular follow-up X-rays of resection site and chest
- prognosis: 10 yr survival 90% for low-grade, 20-40% for high-grade

Ewing’s Sarcoma
- malignant, small round cell sarcoma
- most occur between 5-25 yr old
- florid periosteal reaction in metaphyses of long bone with diaphyseal extension
- metastases frequent without treatment
- signs/symptoms: presents with pain, mild fever, erythema, and swelling; anemia, increased WBC, ESR, LDH (mimics an infection)
- radiographic findings: moth-eaten appearance with periosteal lamellated pattern (“onion-skinning”)
- treatment: resection, chemotherapy, radiation
- prognosis – 70% survival, worst prognostic factor is distant metastases

Multiple Myeloma
- proliferation of neoplastic plasma cells
- most common primary malignant tumour of bone in adults (~43%)
- 90% occur in people >40 yr old, M:F = 2:1; twice as common in African-Americans
- signs/symptoms: localized bone pain (cardinal early symptom), compression/pathological fractures, renal failure, nephritis, high incidence of infections (e.g. pyelonephritis/pneumonia), systemic (weakness, weight loss, anorexia)
- labs: anemia, thrombocytopenia, increased ESR, hypercalcemia, increased Cr
- radiographic findings: multiple, “punched-out” well-demarcated lesions, no surrounding sclerosis, marked bone expansion
- diagnosis
  - serum/urine immunoelectrophoresis (monoclonal gammopathy)
  - CT-guided biopsy of lytic lesions at multiple bony sites
Common Medications

- treatment: chemotherapy, bisphosphonates, radiation, surgery for symptomatic lesions or impending fractures – debulking, internal fixation
- prognosis: 5 yr survival 30%; 10 yr survival 11%
- see Hematology, H49

Bone Metastases
- most common cause of bone lesions in adults; typically age >40
- 2/3 from breast or prostate; also consider thyroid, lung, kidney
- usually osteolytic; prostate occasionally osteoblastic
- may present with mechanical pain and/or night pain, pathological fracture, hypercalcemia
- bone scan for MSK involvement, MRI for spinal involvement may be helpful
- treatment: pain control, bisphosphonates, stabilization of impending fractures if Mirel’s Criteria >8 (ORIF, IM rod, bone cement)

Table 26. Mirel’s Criteria for Impending Fracture Risk and Prophylactic Internal Fixation

Anatomical Triangles of the Neck

Anterior triangle
• bounded by anterior border of SCM, midline of neck, and lower border of mandible
• divided into:
  - submental triangle: bounded by both anterior belly of digastric and hyoid bone
  - digastric triangle: bounded by anterior and posterior bellies of digastric and inferior border of mandible
  - carotid triangle: bounded by sternocleidomastoid, anterior border of omohyoid, and posterior belly of digastric
  - contains tail of parotid, submandibular gland, hypoglossal nerve, carotid bifurcation, and lymph nodes

Posterior triangle
• bounded by posterior border of sternocleidomastoid, anterior border of trapezius, and middle third of clavicle
• divided into:
  - occipital triangle: superior to posterior belly of omohyoid
  - subclavian triangle: inferior to posterior belly of omohyoid
  - contains: spinal accessory nerve and lymph nodes

***Includes pretracheal, pre-cricoid, paratracheal, and prethyroidal nodes
Differential Diagnoses of Common Presentations

**Dizziness**

- **True Vertigo**
  - Peripheral (Vestibular)
    - Benign paroxysmal positional vertigo (BPPV)
    - Labyrinthitis
    - Ménière's disease
    - Vestibular neuritis
    - Autoimmune inner ear disease
    - Cholesteatoma
    - Ototoxic drug exposure
    - Perilymph fistula
    - Recurrent vestibulopathy
    - Superior semicircular canal dehiscence
    - Temporal bone fracture
  - Central
    - Cerebrovascular disorders
    - Vertebrobasilar insufficiency
    - Transient ischemic attacks
    - Wallenberg's syndrome
    - Cerebellar infarction
    - Migraineus vertigo
    - Multiple sclerosis
    - Inflammation
    - Meningitis
    - Cerebellar abscess
    - Trauma: cerebellar contusion
    - Toxic: alcohol, hypnотics, drugs
    - Tumours
    - CPA tumours
    - Posterior fossa tumours
    - Glomus tumour

- **Non-Vertiginous**
  - Organic Diseases
    - Cardiac
      - Arrhythmias
      - Aortic stenosis
      - Vasovagal
    - Orthostatic hypotension
    - Anemia
    - Peripheral neuropathy
    - Visual impairment
  - Functional
    - Depression
    - Anxiety
    - Panic disorder
    - Personality disorder
    - Phobic dizziness

True nystagmus and vertigo caused by a peripheral lesion will never last longer than a few weeks, due to compensation from the cerebellum (unless there is a history of cerebellar ischemia/stroke). Central lesions do not compensate, therefore nystagmus and vertigo will persist.

5 “D”s of Vertebrobasilar Insufficiency
- Drop attacks
- Diplopia
- Dysarthria
- Dizziness
- Dysphagia

**Otalgia**

- **External Ear**
  - Infection
    - Auricular cellulitis
    - External canal abscess
    - Herpes simplex/zoster
    - Otis externa
  - Trauma
    - Burns
    - Frostbite
    - Hematoma
    - Lacerations
    - Other
    - Cerumen impaction
    - Foreign body
    - Ne. plasm of external canal

- **Middle Inner Ear**
  - Infection
    - AOM
    - Mastoiditis
    - Myringitis
    - Otis media with effusion
    - Skull base infections
  - Trauma
    - Barotrauma
    - Traumatic perforation
    - Other
    - Cholesteatoma
    - Neoplasm
    - Wegener's granulomatosis

- **Referred Pain**
  - Infection
    - Ramsay Hunt syndrome
    - Tonsillitis
    - Tracheitis
  - Trauma
    - Cervical arthritus
    - Thyroditis
  - Other
    - Glossopharyngeal neuralgia
    - Neoplasm of oral cavity, larynx, pharynx
    - Teeth
    - TMJ syndrome
    - Trismus

Figure 11. Differential diagnosis of dizziness

Figure 12. Differential diagnosis of otalgia
**Hearing Loss**

**Conductive**
- External Ear
  - Impacted cerumen
  - Otitis externa
  - Foreign body
  - Keratosis obturans
  - Exostoses, osteomas
  - Tumour of canal
  - Congenital stenosis/microtia
- Middle Ear
  - AOM
  - Otitis media with effusion
  - Otosclerosis
  - Tympanosclerosis
  - Eustachian tube dysfunction
  - Cholesteatoma
  - Ossicular malformations
  - Ossicular discontinuity
  - Hernytaurix
  - Middle ear tumour

**Sensorineural**
- Genetic
  - Non-syndrome associated
  - Syndrome associated
  - Intrauterine infections (i.e. TORCH)
  - Teratogens
  - Perinatal hypoxia
  - Prematurity/low birth weight
  - Hyperbilirub nema
- Presbycusis
  - Noise-induced
  - Menière’s disease
  - Labyrinthitis
  - Sudden SNHL
  - Autoimmune inner ear disease
  - Ototoxic drug exposure
  - Temporal bone trauma
  - Infectious
    - Postmeningitis
    - Syphilis
    - Viral: mumps, CMV, HSV
  - Neoplastic
    - Acoustic neuroma
    - CPA tumours
    - Vascular occlusion
    - Auditory neuropathy

Common causes in bold

**Figure 13. Differential diagnosis of hearing loss**

**Tinnitus**

**Subjective**
- Only heard by patient (common)
  - Otologic
    - Presbycusis
    - Noise-induced hearing loss
    - Otitis media with effusion
    - Menière’s disease
    - Otosclerosis
    - Cerumen
    - Foreign body against TM
    - Drugs
      - ASA
      - NSAIDs
      - Aminoglycosides
      - Ant hypertensives
      - Heavy metals
      - Metabolic
        - Hyper/hypothyroidism
        - Hyperlipidemia
      - Vitamin A, B, Zinc deficiency
      - Neurologic
        - Head trauma
        - Multiple sclerosis
        - CPA tumours
        - Psychiatric
        - Anxiety
        - Depression

**Objective**
- Can be heard by others (rare)
  - Vascular
    - Benign intracranial hypertension
      - Arteriovenous malformation
      - Glomus tympanicum
      - Glomus jugulare
    - Arterial bruits:
      - High-riding carotid artery
      - Vascular loop
      - Persistent stapedial artery
      - Carotid stenosis
    - Venous hum:
      - High jugular bulb
      - Hypertension
      - Hyper/hypothyroidism
  - Mechanical
    - Patulous eustachian tube
    - Palatal myoclonus
    - Stapedius muscle spasm

Lung malignancy is the most common cause of extralaryngeal vocal cord paralysis.
Neck Mass

Figure 15. Differential diagnosis of a neck mass

Hearing

Normal Hearing Physiology

- **conductive pathway** (EAC to cochlea): air conduction of sound down the EAC → vibration of TM → sequential vibration of middle ear ossicles (malleus, incus, stapes) → transmission of amplified vibrations from stapes footplate to the oval window of the cochlea → transmitted vibrations via cochlear fluid create movement along the basilar membrane within the cochlea

- **neural pathway** (nerve to brain): basilar membrane vibration stimulates overlying hair cells in the organ of Corti → stimulation of bipolar neurons in the spiral ganglion of the cochlear division of CN VIII → cochlear nucleus → superior olivary nucleus → lateral lemniscus → inferior colliculus → Sylvian fissure of temporal lobe

Types of Hearing Loss

1. **Conductive Hearing Loss**
   - conduction of sound to the cochlea is impaired
   - can be caused by external and middle ear disease

2. **Sensorineural Hearing Loss**
   - defect in the conversion of sound into neural signals or in the transmission of those signals to the cortex
   - can be caused by disease of the inner ear (cochlea), acoustic nerve (CN VIII), brainstem, or cortex

3. **Mixed Hearing Loss**
   - combination of conductive and sensorineural hearing loss

Auditory Acuity

- whispered-voice test: mask one ear and whisper into the other tuning fork tests (see Table 4; audiogram is of greater utility)
  - Rinne test
    - 512 Hz tuning fork is struck and held firmly on mastoid process to test bone conduction (BC); the tuning fork is then placed beside the pinna to test air conduction (AC)
    - If AC > BC → positive Rinne (normal)
  - Weber test
    - 512 Hz tuning fork is held on vertex of head and patient states whether it is heard centrally (Weber negative) or is lateralized to one side (Weber right, Weber left)
    - can place vibrating fork on patient’s chin while they clench their teeth, or directly on teeth to elicit more reliable response
    - will only lateralize if difference in hearing loss between ears is > 6 dB

Order of the Neural Pathway (with corresponding waves on ABR)

E COUL
  - Eighth cranial nerve (I – II)
  - Cochlear nucleus (III)
  - Superior olivary nucleus
  - Lateral lemniscus (IV – V)
  - Inferior colliculus

The Weber test is more sensitive in detecting conductive hearing loss than the Rinne test.

</tr>
</tbody>
</table>

*A vibrating tuning fork on the mastoid stimulates the cochlea bilaterally, therefore in this case the left cochlea is stimulated by the Rinne test on the right (e.g. a false negative test). These tests are not valid if the ear canals are obstructed with cerumen (e.g. will create conductive loss).

**Pure Tone Audiometry**

- a threshold is the lowest intensity level at which a patient can hear the tone 50% of the time
- thresholds are obtained for each ear at frequencies of 250, 500, 1000, 2000, 4000, and 8000 Hz
- air conduction thresholds are obtained with headphones and measure outer, middle, inner ear, and auditory nerve function
- bone conduction thresholds are obtained with bone conduction oscillators which bypass the outer and middle ear

**Degree of Hearing Loss**

- determined on basis of the pure tone average (PTA) at 500, 1000, and 2000 Hz

**Figure 16** Types of hearing loss and associated audiograms of a left ear

**PURE TONE PATTERNS**

1. **Conductive Hearing Loss** (Figure 16B and 16C)
   - BC in normal range
   - AC outside of normal range
   - gap between AC and BC thresholds >10 dB (an air-bone gap)

2. **Sensorineural Hearing Loss** (Figure 16D and 16E)
   - both air and bone conduction thresholds below normal
   - gap between AC and BC <10 dB (no air-bone gap)

3. **Mixed Hearing Loss**
   - both air and bone conduction thresholds below normal
   - gap between AC and BC thresholds >10 dB (an air-bone gap)
**Speech Audiometry**

**Speech Reception Threshold**
- lowest hearing level at which patient is able to repeat 50% of two syllable words which have equal emphasis on each syllable (spondee words)
- SRT and best pure tone threshold in the 500 to 2000 Hz range (frequency range of human speech) usually agree within 5 dB; if not, suspect a retrocochlear lesion or functional hearing loss
- used to assess the reliability of the pure tone audiometry

**Speech Discrimination Test**
- percentage of words the patient correctly repeats from a list of 50 monosyllabic words
- tested at 40 dB above the patient's SRT, therefore degree of hearing loss is taken into account
- rollover effect: a decrease in discrimination as sound intensity increases; typical of a retrocochlear lesion (e.g. acoustic neuroma)
- investigate further if scores differ more than 20% between ears, as asymmetry may indicate a retrocochlear lesion
- best predictor of hearing aid response: a poor discrimination score indicates significant neural degeneration and hearing aids may not be the best option for the patient

**Impedance Audiometry**

**Tympanogram**
- the Eustachian tube equalizes the pressure between the external and middle ear
- tympanograms graph the compliance of the middle ear system against a pressure gradient ranging from to –400 to +200 mmH2O
- tympanogram peak occurs at the point of maximum compliance: where the pressure in the external canal is equivalent to the pressure in the middle ear
- normal range: –100 to +50 mmH2O

Figure 17. Tympanograms

**Static Compliance**
- volume measurement reflecting overall stiffness of the middle ear system
- normal range: 0 3-1.6 cc
- negative middle ear pressure and abnormal compliance indicate middle ear pathology
- in a type B curve, ear canal volumes of >2 cc in children and >2.5 cc in adults indicate TM perforation or presence of a patent ventilation tube

**Acoustic Stapedial Reflexes**
- stapedius muscle contracts in response to loud sound
- acoustic reflex threshold = 70-100 dB greater than hearing threshold; if hearing threshold >85 dB, reflex likely absent
  - if reflex is absent without conductive or severe sensorineural loss, suspect CN VII lesion
- acoustic reflex decay test = ability of stapedius muscle to sustain contraction for 10 s at 10 dB
  - normally, little reflex decay occurs at 500 and 1000 Hz
  - with cochlear hearing loss, acoustic reflex thresholds are 25-60 dB
  - with retrocochlear hearing loss (acoustic neuroma), absent acoustic reflexes or marked reflex decay (>50%) within 5 s
Auditory Brainstem Response

- measures neuroelectric potentials (waves) in response to a stimulus in five different anatomic sites (see Order of Neural Pathway sidebar on OT9; this test can be used to determine the site of lesion)
- delay in brainstem response suggests cochlear or retrocochlear abnormalities
- does not require volition or co-operation of patient (therefore, of value in children and malingers)

Otoacoustic Emissions

- objective test of hearing where a series of clicks is presented to the ear and the cochlea generates an echo which can be measured
- often used in newborn screening
- can be used to uncover normal hearing in malingering patients
- absence of emissions can be due to hearing loss or fluid in the middle ear

Aural Rehabilitation

- dependent on degree of hearing loss, communicative requirements, motivation, expectations, and physical and mental abilities
- negative prognostic factors
  - poor speech discrimination
  - narrow dynamic range (recruitment)
  - unrealistic expectations
- types of hearing aids
  - BTE: behind-the-ear (with occlusive mould or open fit which allows natural sound to pass – for milder hearing losses)
  - ITE: in-the-ear, placed in concha
  - ITC: in-the-canal, placed entirely in ear canal
  - CIC: contained-in-canal, placed deeply in ear canal
  - bone conduction – bone-anchored hearing aid (BAHA): attached to the skull
- contralateral routing of signals (CROS)
- assistive listening devices
  - direct/indirect audio output
  - infrared, FM radio, or induction loop systems
  - telephone, television, or alerting devices
- cochlear implants
  - electrode is inserted into the cochlea to allow direct stimulation of the auditory nerve
  - for profound bilateral sensorineural hearing loss not rehabilitated with conventional hearing aids
  - established indication: post-lingually deafened adults, pre-and post-lingually deaf children

Vertigo

Evaluation of the Dizzy Patient

- vertigo: illusion of rotational, linear, or tilting movement of self or environment
- vertigo is produced by peripheral (inner ear) or central (brainstem cerebellum) stimulation
- it is important to distinguish vertigo from other potential causes of "dizziness" (see Figure 11, OT6)

**Benign Paroxysmal Positional Vertigo**

**Definition**
- acute attacks of transient rotatory vertigo lasting seconds to minutes, initiated by certain head positions, accompanied by torsional (i.e. rotatory) nystagmus (geotropic = fast phase towards the floor)
- most common form of positional vertigo (50% of patients with peripheral vestibular dysfunction)

**Etiology**
- due to canalithiasis (migration of free floating otoliths within the endolymph of the semicircular canal) or cupulolithiasis (otolith attached to the cupula of the semicircular canal)
  - can affect each of the 3 semicircular canals, although the posterior canal is affected in >90% of cases
  - causes: head injury, viral infection (URTI), degenerative disease, idiopathic
  - results in slightly different signals being received by the brain from the two balance organs, resulting in sensation of movement

**Diagnosis**
- history (time course, provoking factors, associative symptoms)
  - positive Dix-Hallpike maneuver (sensitivity 82%, specificity 71%)

**Dix-Hallpike Positional Testing (see website for video and illustrations)**
- the patient is rapidly moved from a sitting position to a supine position with the head hanging over the end of the table, turned to one side at 45°, and neck extended 20° holding the position for 20 s
  - onset of vertigo and rotary nystagmus indicate a positive test for the dependent side
  - other diagnostic testing is not indicated in posterior canal BPPV

**Treatment**
- reassure patient that process resolves spontaneously
  - particle repositioning maneuvers
  - Epley maneuver (performed by MD or by patient with the help of devices such as the DizzyFIX™)
  - Brandt-Daroff exercises (performed by patient)
  - surgery for refractory cases
  - an i-emetics for N/V
  - drugs to suppress the vestibular system delay eventual recovery and are therefore not used

**Ménière’s Disease (Endolymphatic Hydrops)**

**Definition**
- episodic attacks of tinnitus, hearing loss, aural fullness, and vertigo lasting minutes to hours

**Proposed Etiology**
- inadequate absorption of endolymph leads to endolymphatic hydrops (over accumulation) that distorts the membranous labyrinth

**Epidemiology**
- peak incidence 40-60 yr
  - bilateral in 35% of cases
Clinical Features
- episodic vertigo, fluctuating low frequency SNHL, tinnitus, and aural fullness
- ± drop attacks (Tumarkin crisis), ± N/V
- vertigo disappears with time (min to h), but hearing loss remains
- early in the disease: fluctuating SNHL
- later stages: persistent tinnitus and progressive hearing loss
- attacks come in clusters and can be debilitating to the patient
- triggers: high salt intake, caffeine, stress, nicotine, and alcohol

Treatment
- acute management may consist of bed rest, antiemetics, antivertiginous drugs (e.g. beta-histine [Serc®], meclizine, dimenhydramine), and anticholinergics (e.g. scopolamine)
- long-term management may include
  - medical
    - low salt diet, diuretics (e.g. hydrochlorothiazide, triamterene, amiloride)
    - Serc® prophylactically to decrease intensity of attacks
    - intratympanic gentamicin to destroy vestibular end-organ, results in complete SNHL
    - intratympanic glucocorticoids (e.g. dexamethasone) may improve vertigo symptoms
  - surgical
    - selective vestibular neurectomy or labyrinthectomy
    - potential benefit for endolymphatic sac decompression or sacculotomy
- must monitor opposite ear, as bilaterality occurs in 35% of cases

Vestibular Neuronitis (Labyrinthitis)

Definition
- acute onset of disabling vertigo often accompanied by N/V and imbalance without hearing loss that resolves over days, leaving a residual imbalance that lasts days to weeks
- vestibular neuronitis: inflammation of the vestibular portion of CN VIII
- labyrinthitis: inflammation of both vestibular and cochlear portions

Etiology
- thought to be due to a viral infection (e.g. measles, mumps, herpes zoster) or post-viral syndrome
- only ~30% of cases have associated URTI symptoms
- labyrinthitis may occur as a complication of acute and chronic otitis media, bacterial meningitis, cholesteatoma, and temporal bone fractures

Clinical Features
- acute phase
  - severe vertigo with N/V and imbalance lasting 1-5 d
  - irritative nystagmus (fast phase towards the offending ear)
  - ataxia: patient tends to veer towards affected side
  - tinnitus and hearing loss in labyrinthitis
- convalescent phase
  - imbalance and motion sickness lasting days to weeks
  - spontaneous nystagmus away from affected side
  - gradual vestibular adaptation requires weeks to months

Treatment
- acute phase
  - bed rest, antivertiginous drugs
  - corticosteroids (methylprednisolone) ± antivirals
  - bacterial infection: treat with IV antibiotics, drainage of middle ear, ± mastoidectomy
- convalescent phase
  - progressive ambulation, especially in the elderly
  - vestibular exercises: involve eye and head movements, sitting, standing, and walking

Acoustic Neuroma (Vestibular Schwannoma)

Definition
- schwannoma of the vestibular portion of CN VIII

Pathogenesis
- starts in the internal auditory canal and expands into cerebellopontine angle (CPA), compressing cerebellum and brainstem
- when associated with type 2 neurofibromatosis (NF2): bilateral acoustic neuromas, juvenile cataracts, meningiomas, and ependymomas

Clinical Features
- usually presents with unilateral SNHL (chronic) or tinnitus
- dizziness and unsteadiness may be present, but true vertigo is rare as tumour growth occurs slowly, and thus compensation occurs
• facial nerve palsy and trigeminal (V1) sensory deficit (corneal reflex) are late complications
• risk factors: exposure to loud noise, childhood exposure to low-dose radiation, history of parathyroid adenoma

**Diagnosis**
- MRI with gadolinium contrast (gold standard)
- audiogram (to assess SNHL)
- poor speech discrimination relative to the hearing loss
- stapedial reflex absent or significant reflex decay
- ABR: increase in latency of the 5th wave
- vestibular tests: normal or asymmetric caloric weakness (an early sign)

**Treatment**
- expectant management if tumour is very small, or in elderly
- definitive management is surgical excision
- other options: gamma knife, radiation

---

**Diseases of the External Ear**

**Cerumen Impaction**

**Etiology**
- ear wax: a mixture of secretions from ceruminous and pilosebaceous glands, squames of epithelium, dust, and debris

**Risk Factors**
- hairy or narrow ear canals, in-the-ear hearing aids, cotton swab usage, osteomata

**Clinical Features**
- hearing loss (conductive)
- ± tinnitus, vertigo, otalgia, aural fullness

**Treatment**
- water or ceruminolytic drops (bicarbonate solution, olive oil, glycerine, Cerumenol®, Cerumenex®)
- manual debridement (by MD)
Exostoses

**Definition**
- bony protuberances in the external auditory canal composed of lamellar bone

**Etiology**
- possible association with swimming in cold water

**Clinical Features**
- usually an incidental finding
  - if large, they can cause cerumen impaction or otitis externa

**Treatment**
- no treatment required unless symptomatic

Otitis Externa

**Definition**
- inflammation of external auditory canal or auricle

**Etiology**
- bacterial (90% of OE): *Pseudomonas aeruginosa, Pseudomonas vulgaris, E. coli, S. aureus*
  - fungal: *Candida albicans, Aspergillus niger*

**Risk Factors**
- associated with swimming (“swimmer’s ear”)
- mechanical cleaning (Q-tips®), skin dermatitis, aggressive scratching
- devices that occlude the ear canal: hearing aids, headphones, etc.
- allergic contact dermatitis, dermatologic conditions (psoriasis, atopic dermatitis)

**Clinical Features**
- **acute**
  - pain aggravated by movement of auricle (traction of pinna or pressure over tragus)
  - otorrhea (sticky, yellow purulent discharge)
  - conductive hearing loss ± aural fullness 2° to obstruction of external canal by swelling and purulent debris
  - posterior auricular lymphadenopathy
  - complicated OE exists if the pinna and/or the periauricular soft tissues are erythematous and swollen
- **chronic**
  - pruritus of external ear ± excoriation of ear canal
  - atrophic and scaly epidermal lining, ± otorrhea, ± hearing loss
  - wide meatus but no pain with movement of auricle
  - tympanic membrane appears normal

**Treatment**
- clean ear under magnification with irrigation, suction, dry swabbing, and C&S
- bacterial etiology
  - antipseudomonal otic drops (e.g. ciprofloxacin) or a combination of antibiotic and steroid (e.g. Cipro HC®)
  - do not use aminoglycoside if the tympanic membrane (TM) is perforated, because of the risk of ototoxicity
  - introduction of fine gauze wick (pope wick) if external canal edematous
  - ± 3% acetic acid solution to acidify ear canal (low pH is bacteriostatic)
  - systemic antibiotics if either cervical lymphadenopathy or cellulitis is present
- fungal etiology
  - repeated debridement and topical antifungals (gentian violet, Mycostatin® powder, boric acid, Locacorten®, Vioform® drops)
  - ± analgesics
- chronic otitis externa (pruritus without obvious infection) → corticosteroid alone (e.g. diprosalic acid)

Malignant (Necrotizing) Otitis Externa (Skull Base Osteomyelitis)

**Definition**
- osteomyelitis of the temporal bone

**Epidemiology**
- occurs in elderly diabetics and immunocompromised patients

**Etiology**
- rare complication of otitis externa
- *Pseudomonas* infection in 99% of cases
Clinical Features
• otalgia and purulent otorrhea that is refractory to medical therapy
• granulation tissue on the floor of the auditory canal

Complications
• cranial nerve palsy (most commonly CN VII>CN X>CN XI)
• systemic infection, death

Management
• imaging: high resolution temporal bone CT scan, gadolinium-enhanced MRI, technetium scan
• requires hospital admission, debridement, IV antibiotics, hyperbaric O2
• may require OR for debridement of necrotic tissue/bone

Diseases of the Middle Ear

Acute Otitis Media and Otitis Media with Effusion
• see Pediatric Otolaryngology, OT38

Chronic Otitis Media
Definition
• an ear with TM perforation in the setting of recurrent or chronic ear infections

Benign
• dry TM perforation without active infection

Chronic Serous Otitis Media
• continuous serous drainage (straw-coloured)

Chronic Suppurative Otitis Media
• persistent purulent drainage through a perforated TM

Cholesteatoma
Definition
• a cyst composed of keratinized desquamated epithelial cells occurring in the middle ear, mastoid, and temporal bone
• two types: congenital and acquired

Congenital
• presents as a “small white pearl” behind an intact tympanic membrane (anterior and medial to the malleus) or as a conductive hearing loss
• believed to be due to aberrant migration of external canal ectoderm during development
• not associated with otitis media/Eustachian tube dysfunction

Acquired (more common)
• primary cholesteatoma
  • frequently associated with retraction pockets in the pars flaccida (may lead to attic cholesteatomas, which are difficult to visualize)
  • often has crusting or desquamated debris on lateral surface
• secondary cholesteatoma
  • pearly mass evident behind TM, frequently associated with marginal perforation
  • may appear as skin that have replaced the mucosa of the middle ear
• the associated chronic inflammatory process causes progressive destruction of surrounding bony structures

Clinical Features
• history of otitis media (especially if unilateral), ventilation tubes, ear surgery
• symptoms
  • progressive hearing loss (predominantly conductive, although may get sensorineural hearing loss in late stage)
  • otalgia, aural fullness, fever
• signs
  • retraction pocket in TM, may contain keratin debris
  • TM perforation
  • granulation tissue, polyp visible on otoscopy
  • malodorous, unilateral otorrhea

Mechanisms of Cholesteatoma Formation
• Epithelial migration through TM perforation (2nd acquired)
• Invagination of TM (1st acquired)
• Metaplasia of middle ear epithelium or basal cell hyperplasia (congenital)
Complications

Investigations

- audiogram and CT scan

Treatment

- there is no conservative therapy for cholesteatoma
- surgical: mastoidectomy ± tympanoplasty ± ossicular reconstruction

Mastoiditis

Definition

infection (usually subperiosteal) of mastoid air cells, most commonly seen approximately two weeks after onset of untreated or inadequately treated acute suppurative otitis media
- more common in children than adults

Etiology

- acute mastoiditis caused by the same organisms as AOM: S. pneumoniae, H. influenzae, M. catarrhalis, S. pyogenes, S. aureus, P. aeruginosa

Clinical Features

- otorrhea
- tenderness to pressure over the mastoid
- retroauricular swelling with protruding ear
- fever, hearing loss, ± TM perforation (late)
- CT radiologic findings: opacification of mastoid air cells by fluid and interruption of normal trabeculations of cells (coalescence)

Treatment

- IV antibiotics with myringotomy and ventilation tubes – usually all that is required acutely
- cortical mastoidectomy
  - debridement of infected tissue allowing aeration and drainage
- indications for surgery
  - failure of medical treatment after 48 h
  - symptoms of intracranial complications
  - aural discharge persisting for 4 wk and resistant to antibiotics

Otosclerosis

Definition

- fusion of stapes footplate to oval window so that it cannot vibrate

Etiology

- autosomal dominant, variable penetrance approximately 40%
- F>M, progresses during pregnancy (hormone responsive)

Clinical Features

- progressive conductive hearing loss first noticed in teens and 20s (may progress to sensorineural hearing loss if cochlea involved)
- ± pulsatile tinnitus
- tympanic membrane normal ± pink blush (Schwartz's sign) associated with the neovascularization of otosclerotic bone
- characteristic dip at 2000 Hz (Carhart's notch) on audiogram (see Figure 16C, OT10)

Treatment

- monitor with serial audiograms if coping with loss
- hearing aid (air conduction, bone conduction, BAHA)
- stapedectomy or stapledotomy (with laser or drill) with prosthesis is definitive treatment

Complications of AOM are rare due to rapid and effective treatment of AOM with antibiotics

Otosclerosis is the 2nd most common cause of conductive hearing loss in 15-50 yr old (after cerumen impaction)
Diseases of the Inner Ear

Congenital Sensorineural Hearing Loss

Hereditary Defects
- non-syndrome associated (70%)
  - often idiopathic, autosomal recessive
  - connexin 26 (GJB2) most common
- syndrome associated (30%)
  - Waardenburg: white forelock, heterochromia iridis (each eye different color), wide nasal bridge, and increased distance between medial canthi
  - Pendred: deafness associated with thyroid gland disorders, SLC26A4 gene enlarged vestibular aqueducts
  - Treacher-Collins: first and second branchial cleft anomalies
  - Alport: hereditary nephritis

Prenatal TORCH Infections
- toxoplasmosis, others (e.g. HIV, syphilis), rubella, CMV, HSV

Perinatal
- Rh incompatibility
- anoxia
- hyperbilirubinemia
- birth trauma (hemorrhage into inner ear)

Postnatal
- meningitis, mumps, measles

High Risk Factors (for hearing loss in newborns)
- low birth weight/prematurity
- perinatal anoxia (low APGARs)
- kernicterus: bilirubin >25 mg/dL
- craniofacial abnormality
- family history of deafness in childhood
- 1st trimester illness: TORCH infections
- neonatal sepsis
- ototoxic drugs
- perinatal infection, including post-natal meningitis
- consanguinity
- 50-75% of newborns with SNHL have at least one of the above risk factors and 90% of these have spent time in the NICU

Treatment
- presence of any risk factor: ABR study performed before leaving NICU and at 3 mo adjusted age
- early rehabilitation improves speech and school performance

Presbycusis

Definition
- SNHL associated with aging (starting in 5th and 6th decades)

Etiology
- hair cell degeneration
- age related degeneration of basilar membrane, possibly genetic etiology
- cochlear neuron damage
- ischemia of inner ear

Clinical Features
- progressive, bilateral hearing loss initially at high frequencies, then middle frequencies
- loss of discrimination of speech, especially with background noise present – patients describe people as mumbling
- recruitment phenomenon: inability to tolerate loud sounds
- tinnitus

Treatment
- hearing aid if patient has difficulty functioning, hearing loss >30-35 dB, and good speech discrimination
- ± lip reading, auditory training, auditory aids (doorbell and phone lights)
Sudden Sensorineural Hearing Loss

Clinical Features
- presents as a sudden onset of significant SNHL (usually unilateral) ± tinnitus, aural fullness
- usually idiopathic, rule out other causes
  - autoimmune causes (e.g. ESR, rheumatoid factor, ANA)
  - MRI to rule out tumour and/or CT to rule out ischemic/hemorrhagic stroke if associated with any other focal neurological signs (e.g. vertigo, ataxia, abnormality of CN V or VII, weakness)

Treatment
- intratympanic or oral corticosteroids within 3 d of onset: prednisone 1 mg/kg/d for 10-14 d

Prognosis
- depends on degree of hearing loss
- 70% resolve within 10-14 d
- 20% experience partial resolution
- 10% experience permanent hearing loss

Autoimmune Inner Ear Disease

Etiology
- idiopathic
- may be associated with systemic autoimmune diseases (e.g. rheumatoid arthritis, SLE), vasculitides (e.g. GPA, polyarteritis nodosa), and allergies

Epidemiology
- most common between ages 20-50

Clinical Features
- rapidly progressive or fluctuating bilateral SNHL
- ± tinnitus, aural fullness, vestibular symptoms (e.g. ataxia, disequilibrium, vertigo)

Investigations
- autoimmune workup: CBC, ESR, ANA, rheumatoid factor

Treatment
- high dose corticosteroids: treat early for at least 30 d
- consider cytotoxic medication for steroid non-responders

Drug Ototoxicity

Aminoglycosides
- streptomycin and gentamicin (vestibulotoxic), kanamycin, and tobramycin (cochleotoxic)
- toxic to hair cells by any route: oral, IV, and topical (if the TM is perforated)
- destroys sensory hair cells: outer first, inner second (therefore, otoacoustic emissions are lost first)
- high frequency hearing loss develops earliest
- ototoxicity occurs days to weeks post-treatment
- must monitor with peak and trough levels when prescribed, especially if patient has neutropenia and/or history of ear or renal problems
- q24h dosing recommended (with amount determined by creatinine clearance)
- aminoglycoside toxicity displays saturable kinetics, therefore, once daily dosing presents less risk than divided daily doses
- duration of treatment is the most important predictor of ototoxicity
  - treatment: immediately stop aminoglycosides

Salicylates
- hearing loss with tinnitus, reversible if discontinued

Antimalarials (Quinines)
- hearing loss with tinnitus
- reversible if discontinued but can lead to permanent loss

Others
- many antineoplastic agents are ototoxic (weigh risks vs. benefits)
- loop diuretics
Noise-Induced Sensorineural Hearing Loss

Pathogenesis
- 85-90 dB over months or years or single sound impulses >135 dB can cause cochlear damage
- bilateral SNHL initially and most prominently at 4000 Hz (resonant frequency of the temporal bone), known as “boilermaker’s notch” on audiogram, extends to higher and lower frequencies with time (see Figure 16D, OT10)
- speech reception not altered until hearing loss >30 dB at speech frequency, therefore considerable damage may occur before patient complains of hearing loss
- difficulty with speech discrimination, especially in situations with competing noise

Phases of Hearing Loss
- dependent on: intensity of sound and duration of exposure
  - temporary threshold shift
    - when exposed to loud sound, decreased sensitivity or increased threshold for sound
    - may have associated aural fullness and tinnitus
  - with removal of noise, hearing returns to normal
  - permanent threshold shift
    - hearing does not return to previous state

Treatment
- hearing aid
- prevention
  - ear protectors: muffs, plugs
  - limit exposure to noise with frequent rest periods
  - regular audiologic follow-up

Temporal Bone Fractures

</tbody>
</table>

- characterized as longitudinal or transverse relative to the long axis of the petrous temporal bone
- temporal bone fractures are rarely purely transverse or longitudinal (often a mixed picture)

Diagnosis
- otoscopy
- do not syringe or manipulate external auditory meatus due to risk of inducing meningitis via TM perforation
- CT head
- audiometry, facial nerve tests (for transverse fractures), Schirmer’s test (of lacrimation), stapedial reflexes if CN VII palsy
- if suspecting CSF leak: look for halo sign, send fluid for β-2 transferrin or β trace protein (prostaglandin D synthase)

Treatment
- ABCs
- medical: expectant, prevent otogenic meningitis
- surgical: explore temporal bone; indications:
  - CN VII palsy (immediate and complete)
  - gunshot wound
  - depressed fracture of external auditory meatus
  - early meningitis (mastoidectomy)
  - bleeding intracranially from sinus
  - CSF otitis (may resolve spontaneously)

Hemotympanum can be indicative of temporal bone trauma

Signs of Basilar Skull Fracture
- Battle’s Sign
- Raccoon Eyes
- CSF Rhinorrhea/Otorrhea
- Cranial Nerve Involvement:
  - facial palsy → CN V, I
  - vestibular → CN V, VI
  - facial numbness → CN V
Complications
- AOM ± labyrinthitis ± mastoiditis
- meningitis/epidural abscess/brain abscess
- post-traumatic cholesteatoma

Facial Nerve (CN VII) Paralysis

Peripheral Facial Paralysis (PFP)
- mononeuropathy of the facial nerve where there is weakening in the facial muscles, which alters facial symmetry and functions
- can have a detectable cause (secondary facial nerve palsy) or may be idiopathic (primary)

Etiology
- supranuclear and nuclear (MS, poliomyelitis, cerebral tumours)
- infranuclear

Treatment
- treat according to etiology, plus provide corneal protection with artificial tears, nocturnal lid taping, tarsorrhaphy, gold weighting of upper lid
- facial paralysis that does not resolve with time or with medical treatment will often be referred for possible reanimation techniques to restore function
- common reanimation techniques include
  - direct facial nerve anastomosis
  - interpositional grafts
  - anastomosis to other motor nerves
  - muscle transpositions

Allergic Rhinitis (i.e. Hay Fever)

Definition
- rhinitis characterized by an IgE-mediated hypersensitivity to foreign allergens
- acute-and-seasonal or chronic-and-perennial
- perennial allergic rhinitis often confused with recurrent colds

Etiology
- when allergens contact the respiratory mucosa, specific IgE antibody is produced in susceptible hosts
- concentration of allergen in the ambient air correlates directly with the rhinitis symptoms

Epidemiology
- age at onset usually <20 yr
- more common in those with a personal or family history of allergies/atopy

Clinical Features
- nasal: obstruction with pruritus, sneezing
- clear rhinorrhea (containing increased eosinophils)
- itching of eyes with tearing
- frontal headache and pressure
- mucosa: swollen, pale, “boggy”
- seasonal (summer, spring, early autumn)
  - pollens from trees
  - lasts several weeks, disappears, and recurs the following year at same time
- perennial
  - inhaled: house dust, wool, feathers, foods, tobacco, hair, mould
  - ingested: wheat, eggs, milk, nuts
  - occurs intermittently for years with no pattern or may be constantly present

Complications
- chronic sinusitis/polyps
- serous otitis media

Rhinitis medicamentosa: rebound congestion due to the overuse of intranasal vasoconstrictors; for prevention, use of these medications for only 5-7 days is recommended

Congestion reduces nasal airflow and allows the nose to repair itself (i.e. washes away the irritants). Treatment should focus on the initial insult rather than target this defense mechanism.
Diagnosis
- history
- direct exam
- allergy testing

Treatment
- education: identification and avoidance of allergen
- nasal irrigation with saline
- antihistamines (e.g. diphenhydramine, fexofenadine)
- oral decongestants (e.g. pseudoephedrine, phenylpropanolamine)
- topical decongestant (may lead to rhinitis medicamentosa)
- other topicals: steroids (fluticasone), disodium cromoglycate, antihistamines, ipratropium bromide
- oral steroids if severe
- desensitization by allergen immunotherapy

**Vasomotor Rhinitis**

Definition
- neurovascular disorder of nasal parasympathetic system (vidian nerve) affecting mucosal blood vessels
- nonspecific reflex hypersensitivity of nasal mucosa

Etiology
- temperature change
- alcohol, dust, smoke
- stress, anxiety, neurosis
- endocrine: hypothyroidism, pregnancy, menopause
- parasympathomimetic drugs
- beware of rhinitis medicamentosa: reactive vasodilation due to prolonged use (>5 d) of nasal drops and sprays (Dristan®, Otrivin®)

Clinical Features
- chronic intermittent nasal obstruction, varies from side to side
- rhinorrhea: thin, watery
- mucosa and turbinates: swollen
- nasal allergy must be ruled out

Treatment
- elimination of irritant factors
- parasympathetic blocker (Atrovent® nasal spray)
- steroids (e.g. beclomethasone, fluticasone)
- surgery (often of limited lasting benefit): electrocautery, cryosurgery, laser treatment, or removal of inferior or middle turbinates
- vidian neurectomy (rarely done)
- symptomatic relief with exercise (increased sympathetic tone)

**Rhinosinusitis**

Definition
- inflammation of the mucosal lining of the sinuses and nasal passages

Pathogenesis of Rhinosinusitis
- ostial obstruction or dysfunctional cilia permit stagnant mucous and, consequently, infection
- all sinuses drain to a common prechamber under the middle meatus called the osteomeatal complex

Classification
- acute: <4 wk
- subacute: 4-8 wk
- chronic: >8-12 wk
## Table 13. Etiologies of Rhinosinusitis

### Acute Bacterial Rhinosinusitis

**Definition**
- bacterial infection of the paranasal sinuses and nasal passages lasting >7 d
- clinical diagnosis requiring ≥2 major symptoms, and at least one of the symptoms is either nasal obstruction or purulent/dischoured nasal discharge

**Major Symptoms (at least 2 of PODS, 1 must be O or D)**
- **P** Facial Pain/Pressure/fullness
- **O** Nasal Obstruction
- **D** Purulent/dischoured nasal Discharge
- **S** Hyposmia/anosmia (Smell)

**Minor Symptoms**
- Headache
- Halitosis
- Fatigue
- Dental pain
- Cough
- Ear pain/fullness

**Etiology**
- bacteria: *S. pneumoniae* (35%), *H. influenzae* (35%), *M. catarrhalis*, *S. aureus*, anaerobes (dental)
- children are more prone to a bacterial etiology, but viral i. still more common
- maxillary sinus most commonly affected
- must rule out fungal causes (mucormycosis) in immunocompromised hosts (especially if painless, black or pale mucosa on examination)

**Clinical Features**
- sudden onset of:
  - nasal blockage/congestion and/or purulent nasal discharge/posterior nasal drip
  - ± facial pain or pressure, hyposmia, sore throat
  - persistent/worsening symptoms >5-7 d or presence of purulence for 3-4 d with high fever
  - speculum exam: erythematous mucosa, mucopurulent discharge, pus originating from the middle meatus
  - predisposing factors: viral URTI, allergy, dental disease, anatomical defects
  - differentiate from acute viral rhinosinusitis (course: <10 d, peaks by 3 d)

**Diagnosis**
- along with clinical criteria, can confirm radiographically and/or endoscopically using antral puncture for bacterial cultures

**Management**
- depends on symptom severity (i.e. intensity/duration of symptoms, impact on quality of life)
  - mild/moderate: INCS
    - if no response within 72 h, add antibiotics
  - severe: INCS + antibiotics
    - antibiotics
      - 1st line: amoxicillin x 10 d (TMP-SMX or macrolide if penicillin allergy)
      - if no response to 1st line antibiotics within 72 h, switch to 2nd line
        - 2nd line: fluoroquinolones or amoxicillin-clavulanic acid
      - adjuvant therapy (saline or HOCL (pediatric sinusitis) irrigation, analgesics, oral/topical decongestant) may provide symptomatic relief
      - CT indicated only if complications are suspected

**Acute Rhinosinusitis Complications**
- Consider hospitalization if any of the following are suspected
  - Orbital (Chandler’s classification)
    - Preseptal cellulitis
    - Subperiosteal abscess
    - Orbital abscess
    - Cavernous sinus thrombosis
  - Intracranial
    - Meningitis
    - Abscess
  - Bony
    - Subperiosteal frontal bone abscess (“Pott’s Puffy tumour”)
    - Osteomyelitis
  - Neurologic
    - Superior orbital fissure syndrome (CN III/IV/VI palsy, immobile globe, dilated pupils, ptosis, V1 hypoesthesia)
    - Orbital apex syndrome (as above, plus neuritis, papilledema, decreased visual acuity)

**Use of Single Dose Azithromycin as Treatment of Acute Bacterial Rhinosinusitis**

*Otolaryngol Head Neck Surg 2005;133(2):194-200*

**Summary:** Single-dose azithromycin microspheres were comparable to 10 days of levofloxacin and may be a safe and effective treatment for acute bacterial rhinosinusitis.

**Results:** An international, multicentre, double-blind, double-dummy RCT comparing single dose azithromycin vs. 10-day levofloxacin group for treatment of acute bacterial rhinosinusitis. Clinical success was 94.5% (242/256) in the azithromycin group and 92.8% (233/251) in the levofloxacin group.
Chronic Rhinosinusitis

Definition
• inflammation of the mucosa of paranasal sinuses and nasal passages >8-12 wk
• diagnosis requires ≥2 major symptoms for >8-12 wk and ≥1 objective finding of inflammation of the paranasal sinuses (CT/endoscopy)

Etiology
• unclear etiology but the following may contribute or predispose
  • inadequate treatment of acute rhinosinusitis
  • bacterial colonization/biofilms
    ■ S. aureus, enterobacteriaceae, Pseudomonas, S. pneumoniae, H. influenzae, β-hemolytic Streptococci
  • fungal infection (e.g. Aspergillus, Zygomycetes, Candida)
  • anatomic abnormality (e.g. lost ostia patency, deviated septum – predisposing factors)
  • allergy/allergic rhinitis
  • ciliary disorder (e.g. cystic fibrosis, Kartagener syndrome)
  • chronic inflammatory disorder (e.g. GPA)
  • untreated dental disease

Clinical Features (similar to acute, but less severe) - at least 2 of CPODS for >8-12 wk
• facial Congestion/fullness
• facial Pain/Pressure
• chronic nasal Obstruction
• purulent anterior/posterior nasal Discharge
• hyposmia/anosmia (Smell)
• others: halitosis, chronic cough, maxillary dental pain

Management
• identify and address contributing or predisposing factors
• obtain CT or perform endoscopy
• if polyps present: INCS, oral steroids ± antibiotics (if signs of infection), refer to otolaryngologist/H&N surgeon
• if polyps absent: INCS, antibiotics, saline irrigation, oral steroids (severe cases)
• antibiotics for 3-6 wk
  ■ amoxillin-clavulanic acid, fluoroquinolone (moxifloxacin), macrolide (clarithromycin), clindamycin, Flagyl® (metronidazole)
• surgery if medical therapy fails or fungal sinusitis FESS, balloon sinoplasty

Complications
• same as acute sinusitis, mucocele

Epistaxis

Blood Supply to the Nasal Septum (see Figure 4, OT3)
1. Superior posterior septum
   • internal carotid → ophthalmic → anterior/posterior ethmoidal
2. Posterior septum
   • external carotid → internal maxillary → sphenopalatine artery → nasopalatine
3. Lower anterior septum
   • external carotid → facial artery → superior labial artery → nasal branch
   • external carotid → internal maxillary → descending palatine → greater palatine
• these arteries all anastomose to form Kiesselbach’s plexus, located at Little’s area (anterior-inferior portion of the cartilaginous septum)
• bleeding from above middle turbinate is internal carotid, from below is external carotid

</tbody>
</table>

**Investigations**
- CBC, PT/PTT (if indicated)
- X-ray, CT as needed

**Treatment**
- locate bleeding and achieve hemostasis

1. **ABCs**
- lean patient forward to minimize swallowing blood and avoid airway obstruction
- apply constant firm pressure for 20 min on cartilaginous part of nose (not bony pyramid)
- if significant bleeding, assess vitals for signs of hemorrhagic shock ± IV NS, cross-match blood

2. **Determine Site of Bleeding**
- anterior/posterior hemorrhage defined by location in relationship to bony septum
- visualize nasal cavity with speculum
- use cotton pledget with topical lidocaine ± topical decongestant (i.e. Otrivin*) to help identify area of bleeding (often anterior septum)
- if suspicious bleeding disorder, coagulation workup (platelet number and platelet function assay)

3. **Control the Bleeding**
- first-line: topical vasoconstrictors (Otrivin*)
  - if first-line fails and bleeding adequately visualized, cauterize with silver nitrate
  - **do not cauterize both sides of the septum** at one time due to risk of septal perforation from loss of septal blood supply
  A. **Anterior hemorrhage treatment**
    - if failure to achieve hemostasis with cauterization
      - place anterior pack* with half inch Vaseline-soaked ribbon gauze strips layered from nasal floor toward nasal roof and extending to posterior choanae, or lubricated absorbable packing (i.e. Gelfoam wrapped in Surgicel*) for 2-3 d
      - can also attempt packing with Merocel* or nasal tampons of different shapes
      - can also apply Floseal* (hemostatic matrix consisting of topical human thrombin and cross-linked gelatin) if other methods fail
  B. **Posterior hemorrhage treatment**
    - if unable to visualize bleeding source, then usually posterior source
      - place posterior pack* using a Foley catheter, gauze pack, or Epistat* balloon
      - subsequently, layer anterior packing bilaterally
      - admit to hospital with packs in for 3-5 d
      - watch for complications: hypoxemia (naso-pulmonic reflex), toxic shock syndrome (Rx: remove packs immediately), pharyngeal fibrosis/stenosis, alar/septal necrosis, aspiration
  C. **If anterior/posterior packs fail to control epistaxis**
    - ligation or embolization of culprit arterial supply by interventional radiology
    - ± septoplasty

*antibiotics for any posterior pack or any pack left for >48 h because of risk of toxic shock syndrome

**Special Cases**
- Adolescent male with unilateral recurrent epistaxis - consider juvenile nasopharyngeal angiofibroma (JNA); this is the most common benign tumour of the nasopharynx.
- Thrombocytopenic patients: use resorbable packs to avoid risk of re-bleeding caused by pulling out the removable pack

**4. Prevention**
- prevent drying of nasal mucosa with humidifiers, saline spray, or topical ointments
- avoidance of irritants
- medical management of HTN and coagulopathies
Hoarseness

Definitions
- **Hoarseness**: change in voice quality, ranging from voice harshness to voice weakness; reflects abnormalities anywhere along the vocal tract from oral cavity to lungs
- **Dysphonia**: a general alteration in voice quality
- **Aphonia**: no sound emanates from vocal folds

Acute Laryngitis

**Definition**
- <2 wk inflammatory changes in laryngeal mucosa

**Etiology**
- Viral: influenza, adenovirus, HSV
- Bacterial: Group A Streptococcus
- Mechanical: acute voice strain → submucosal hemorrhage → vocal cord edema → hoarseness
- Environmental: toxic fume inhalation

**Clinical Features**
- URTI symptoms, hoarseness, aphonia, cough attacks, ± dyspnea
- True vocal cords erythematous/edematous with vascular injection and normal mobility

**Treatment**
- Usually self-limited, resolves within ~1 wk
- Voice rest
- Humidification
- Hydration
- Avoid irritants (e.g., smoking)
- Treat with antibiotics if there is evidence of coexistent bacterial pharyngitis

Chronic Laryngitis

**Definition**
- >2 wk inflammatory changes in laryngeal mucosa

**Etiology**
- Repeated attacks of acute laryngitis
- Chronic irritants (dust, smoke, chemical fumes)
- Chronic voice strain
- Chronic rhinosinusitis with postnasal drip
- Chronic EtOH use
- Esophageal disorders: GERD, Zenker’s diverticulum, hiatus hernia
- Systemic: allergy, hypothyroidism, Addison’s disease

**Clinical Features**
- Chronic dysphonia: rule out malignancy
- Cough, globus sensation, frequent throat clearing 2° to GERD
- Laryngoscopy: cords erythematous, thickened with ulceration/granuloma formation, and normal mobility

**Treatment**
- Remove offending irritants
- Treat related disorders (e.g., antisecretory therapy for GERD)
- Speech therapy with voice rest
- ± Antibiotics ± steroids to decrease inflammation
- Laryngoscopy to rule out malignancy

Vocal Cord Polyps

**Definition**
- Structural manifestation of vocal cord irritation
- Acutely, polyp forms 2° to capillary damage in the subepithelial space during extreme voice exertion

**Etiology**
- Most common benign tumour of vocal cords
- Voice strain (muscle tension dysphonia)
- Laryngeal irritants (GERD, allergies, tobacco)
Epidemiology
- 30-50 yr of age
- M>F

Clinical Features
- hoarseness, aphonia, cough attacks ± dyspnea
- pedicled or sessile polyp on free edge of vocal cord
- typically, polyp asymmetrical, soft, and smooth
- more common on the anterior 1/3 of the vocal cord
- intermittent respiratory distress with large polyps

Treatment
- avoid irritants
- endoscopic laryngeal microsurgical removal if persistent or if high risk of malignancy

Vocal Cord Nodules

Definition
- vocal cord callus
- i.e. "screamer's or singer's nodules"

Etiology
- early nodules occur 2° to submucosal hemorrhage
- mature nodules result from hyalinization, which occurs with long-term voice abuse
- chronic voice strain
- frequent URTI, smoke, EtOH

Epidemiology
- frequently in singers, children, bartenders, and school teachers
- F>M

Clinical Features
- hoarseness worst at end of day
- on laryngoscopy
  - often bilateral
  - at the junction of the anterior 1/3 and posterior 2/3 of the vocal cords – point of maximal cord vibration
- chronic nodules may become fibrotic, hard, and white

Treatment
- voice rest
- hydration
- speech therapy
- avoid irritants
- surgery rarely indicated for refractory nodules

Benign Laryngeal Papillomas

Etiology
- HPV types 6, 11
- possible hormonal influence, possibly acquired during delivery

Epidemiology
- biphasic distribution: 1) birth to puberty (most common laryngeal tumour) and 2) adulthood

Clinical Features
- hoarseness and airway obstruction
  - can seed into tracheobronchial tree
  - highly resistant to complete removal
- some juvenile papillomas resolve spontaneously at puberty
- may undergo malignant transformation
- laryngoscopy shows wart-like lesions in supraglottic larynx and trachea

Treatment
- microdebridement or CO2 laser
- adjuvants under investigation: interferon, cidofovir, acyclovir
- HPV vaccine may prevent/decrease the incidence, but more research is needed

Laryngeal Carcinoma

- see Neoplasms of the Head and Neck, OT34
**Salivary Glands**

### Sialadenitis

**Definition**
- inflammation of salivary glands

**Etiology**
- viral most common (mumps)
- bacterial causes: *S. aureus, S. pneumoniae, H. influenzae*
- obstructive vs. non-obstructive
  - obstructive infection involves salivary stasis and bacterial retrograde flow

**Predisposing Factors**
- HIV
- anorexia/bulimia
- Sjögren’s syndrome
- Cushing’s, hypothyroidism, DM
- hepatic/renal failure
- meds that increase stasis: diuretics, TCAs, β-blockers, anticholinergics, antibiotics
- sialolithiasis (can cause chronic sialadenitis)

**Clinical Features**
- acute onset of pain and edema of parotid or submandibular gland that may lead to marked swelling
- ± fever
- ± leukocytosis
- ± suppurative drainage from punctum of the gland

**Investigations**
- U/S imaging to differentiate obstructive vs. non-obstructive sialadenitis

**Treatment**
- bacterial: treat with cloxacillin ± abscess drainage, sialogogues
- viral: no treatment

### Sialolithiasis

**Definition**
- ductal stone (mainly hydroxyapatite) in adults, sand/sludge in children, leading to chronic sialadenitis
- 80% in submandibular gland, <20% in parotid gland, ~1% in sublingual gland

**Risk Factors**
- any condition causing duct stenosis or a change in salivary secretions (e.g. dehydration, diabetes, EtOH, hypercalcemia, psychiatric medication)

**Clinical Features**
- pain and tenderness over involved gland
- intermittent swelling related to meals
- digital palpation reveals presence of calculus

**Investigations**
- U/S ± sialogram

**Treatment**
- may resolve spontaneously
- encourage salivation to clear calculus
- massage, analgesia, antibiotics, sialogogues (e.g. lemon wedges, sour lemon candies), warm compresses
- remove calculi endoscopically, by dilating duct or orifice, or by excision through floor of the mouth
- gland preserving surgery has long-term symptom improvement and favourable gland retention rates

### Salivary Gland Neoplasms

**Etiology**
- anatomic distribution
  - parotid gland: 70-85%
  - submandibular gland: 8-15%
  - sublingual gland: 1%
  - minor salivary glands, most concentrated in hard palate: 5-8%
neck masses

• malignant (see Table 15, OT31 and Table 16, OT35)
• benign
  • benign mixed (pleomorphic adenoma): 80%
  • Warthin’s tumour (5-10% bilateral, M>F): 10%
  • cysts, lymph nodes, and adenomas: 10%
  • oncocytoma: <1%

Epidemiology
• 3-6% of all head and neck neoplasms in adults
• mean age at presentation: 55-65
• M=F

Parotid Gland Neoplasms

Clinical Features
• 80% benign (pleomorphic adenoma: most common), 20% malignant (mucoepidermoid: most common)
• if bilateral, suggests benign process (Warthin’s tumour, Sjögren’s, bulimia, mumps) or possible lymphoma
• facial nerve involvement (i.e. facial paralysis): increases risk of malignancy

Investigations
• FNA biopsy
• CT, U/S, or MRI to determine extent of tumour

Treatment
• treatment of choice is surgery for all salivary gland neoplasms – benign and malignant
• pleomorphic adenomas are excised due to risk of malignant transformation (5% risk over prolonged period of time)
• superficial tumour
  • superficial parotidectomy above plane of CN VII ± radiation
  • incisional biopsy contraindicated
• deep lesion
  • near-total parotidectomy sparing as much of CN VII as possible
  • if CN VII involved, then it is removed and cable grafted
• complications of parotid surgery
  • hematoma, infection, salivary fistula, temporary facial paresis, Frey’s syndrome (gustatory sweating)

Prognosis
• benign: excellent, <5% of pleomorphic adenomas may recur
• malignant: dependent on stage and type of malignancy (see Table 16, OT35)

Approach to a Neck Mass

• ensure that the neck mass is not a normal neck structure (hyoid, transverse process of C1 vertebra, prominent carotid bulb)
• any neck mass persisting for >2 wk should be investigated for possible neoplastic causes

Table 15. Acquired Causes of Neck Lumps According to Age

<table>
<thead>
<tr>
<th>Age (yr)</th>
<th>Possible Causes of Neck Lump</th>
</tr>
</thead>
<tbody>
<tr>
<td>20-40</td>
<td>1. Inflammatory 2. Congenital 3. Neoplastic</td>
</tr>
<tr>
<td>&gt;40</td>
<td>1. Neoplastic 2. Inflammatory 3. Congenital</td>
</tr>
</tbody>
</table>

Differential Diagnosis
• congenital
  • lateral (branchial cleft cyst, lymphatic/venous/venolymphatic malformation)
  • midline (thyroglossal duct cyst, dermoid cyst, laryngocele, thyroid/thymus anomaly, vascular malformation)
• infectious/inflammatory
  • reactive lymphadenopathy (2° to tonsillitis, pharyngitis)
  • infectious mononucleosis
  • Kawasaki, Kikuchi, Kimura, Cat-scratch disease, Castleman’s
  • HIV
  • salivary gland calculi, sialadenitis
  • thyroiditis

DDx Parotid Tumour
Benign
• Pleomorphic adenoma
• Warthin’s tumour (more common in men)
• Benign lymphoepithelial cysts (viral etiology e.g. HIV)
• Oncocytoma

Malignant
• Mucoepidermoid carcinoma
• Adenoid cystic carcinoma
• Acinic cell carcinoma

Frey’s syndrome is a post-operative complication characterized by gustatory sweating. It is due to aberrant innervation of cutaneous sweat glands by parasympathetic nerve fibres that are divided during surgery.
Congenital Neck Masses

- granulomatous disease
  - mycobacterial infections
  - sarcoidosis
- neoplastic
  - lymphoma
  - salivary gland tumours
  - thyroid tumours
  - metastatic malignancy (“unknown primary”)

**Evaluation**

**Investigations**
- history and physical (including nasopharynx and larynx)
- all other investigations and imaging are dependent upon clinical suspicion following history and physical
- laboratory investigations
  - WBC: infection vs. lymphoma
  - Mantoux TB test
  - thyroid function tests and scan
- imaging
  - neck U/S
  - CT scan
  - angiography: vascularity and blood supply to mass
  - biopsy: for histologic examination
    - FNA: least invasive
    - needle biopsy
    - open biopsy: for lymphoma
- identification of possible primary tumour (rule out a metastatic lymph node from an “unknown primary”)
  - panendoscopy: nasopharyngoscopy, laryngoscopy, esophagoscopy, bronchoscopy with washings, and biopsy of suspicious lesions
  - biopsy of normal tissue of nasopharynx, tonsils, base of tongue, and hypopharynx
  - primary identified 95% of time → stage and treat
  - primary occult 5% of time: excisional biopsy of node for histologic diagnosis → manage with radiotherapy and/or neck dissection (squamous cell carcinoma)

**Congenital Neck Masses**

**Brachial Cleft Cysts/Sinuses/Fistulae**

**Embryology**
- at the 6th wk of development, the 2nd branchial arch grows over the 3rd and 4th arches and fuses with the neighbouring caudal pre-cardial swelling, forming the cervical sinus
- 3 types of malformations
  1. branchial fistula: persistent communication between skin and GI tract
  2. branchial sinus: blind-ended tract opening to skin
  3. branchial cyst: persistent cervical sinus with no external opening

**Clinical Features**
- 2nd branchial cleft malformations most common
  - sinuses and fistulae present in infancy as a small opening anterior to the sternocleidomastoid muscle
  - cysts present as a smooth, painless, slowly enlarging lateral neck mass, often following a URTI
- 1st branchial cleft malformations present as sinus/fistula or cyst in preauricular area or on face over angle of mandible
- 3rd branchial cleft malformations present as recurrent thyroiditis or thyroid abscess and have a tract leading usually to the left pyriform sinus. Air on CT scan in or near the thyroid gland is pathognomonic for this anomaly
- there is controversy whether or not 4th branchial cleft anomalies exist, as they may be remnants of the thyrothyroidic axis

**Treatment**
- surgical removal of cyst or fistula tract
- if infected: allow infection to settle before removal (antibiotics may be required)

Thyroglossal Duct Cysts

Embryology
- thyroid originates as ventral midline diverticulum at base of tongue, caudal to junction of 3rd and 4th branchial arches (foramen cecum), and migrates down to inferior aspect of neck
- thyroglossal duct cysts are vestigial remnants of this tract

Clinical Features
- usually presents in childhood or during 20-40s as a midline cyst that enlarges with URTI and elevates with swallowing and tongue protrusion

Treatment
- pre-operative antibiotics to reduce inflammation (infection before surgery is a well-described cause of recurrence)
- small potential for neoplastic transformation, so complete excision of cyst and issue around tract up to foramen cecum at base of tongue, with removal of central portion of hyoid bone (Sistrunk procedure) recommended
Lymphatic, Venous, or Mixed Venolymphatic Malformations

Definition
- lymphatic malformation arising from vestigial lymph channels of neck

Clinical Features
- commonly identified in many fetuses, but regress before birth and never cause a clinical problem
- usually present by age 2
- can be macrocystic (composed of large thin-walled cysts, usually below level of mylohyoid muscle) or microcystic (composed of minute cysts, usually above level of mylohyoid muscle)
- usually painless, soft, compressible
- infection or trauma causes a sudden increase in size

Treatment
- can regress spontaneously after bacterial infection, therefore do not plan surgical intervention until several months after infection
- macrocystic lesions can be treated by sclerotherapy or surgical excision
- microcystic lesions are difficult to treat, but can be debulked if it will not cause loss of function of normal structures, or injected with sclerotherapy in surrounding tissues

Neoplasms of the Head and Neck

Pre-Malignant Disease
- leukoplakia
  - hyperkeratosis of oral mucosa
  - risk of malignant transformation 5-20%
- erythroplakia
  - red superficial patches adjacent to normal mucosa
  - commonly associated with epithelial dysplasia
  - associated with carcinoma in situ or invasive tumour in 40% of cases
- dysplasia
  - histopathologic presence of mitoses and prominent nucleoli
  - involvement of entire mucosal thickness = carcinoma in situ
  - associated progression to invasive cancer in 15-30% of cases

Investigations
- initial metastatic screen includes CXR
- scans of liver, brain, and bone only if clinically indicated
- CT scan is superior to MRI for the detection of pathologic nodal disease and bone cortex invasion
- MRI is superior to discriminate tumour from mucus and to detect bone marrow invasion
- ± PET scans

Treatment
- treatment depends on
  - histologic grade of tumour
  - stage
  - physical and psychological health of patient
  - facilities available
  - expertise and experience of the medical and surgical oncology team
- in general
  - 1st surgery for malignant oral cavity tumours with radiotherapy reserved for salvage or poor prognostic indicators
  - 1st radiotherapy for nasopharynx, oropharynx, hypopharynx, larynx malignancies with surgery reserved for salvage
  - palliative chemotherapy for metastatic or incurable disease
  - concomitant chemotherapy increases survival in advanced disease
  - chemotherapy has a role as induction therapy prior to surgery and radiation
  - panendoscopy to detect primary disease when lymph node metastasis is identified
  - anti-EGFR treatment (cetuximab, panitumumab) has a role as concurrent therapy with radiation for SCC of the head and neck (for advanced local and regional disease)

Prognosis
- synchronous tumours occur in 9-15% of patients
- late development of 2nd primary is most common cause of post treatment failure after 36 mo

Approach to Thyroid Nodule
- all patients with thyroid nodules require evaluation of serum TSH and ultrasound
- intermediate-high suspicion nodule >1 cm and low suspicion nodule >1.5 cm should undergo FNA
- nodules <1 cm with clinical symptoms or lymphadenopathy may require further evaluation
- when performing repeat FNA on initially non-diagnostic nodules, U/S-guided FNA should be employed
- nuclear scanning has minimal value in the investigation of the thyroid nodule

* U/S findings: cyst c: risk of malignancy < 1%; solid risk of malignancy - 10%; solid with cystic c: imprints: risk of malignancy same as if solid
Acute Otitis Media

Definition
all of: presence of middle ear effusion (MEE); presence of middle ear inflammation (MEI); acute onset of symptoms of MEE and MEI

Epidemiology
- most frequent diagnosis in sick children visiting clinicians' offices and most common reason for antibiotic administration
- peak incidence between 6–15 mo; ~85% of children have >1 episode by 3 yr old
- seasonal variability: peaks in winter

Etiology
- primary defect causing AOM: Eustachian tube dysfunction/obstruction → stasis/colonization by pathogens
- bacterial: *S pneumoniae*, non-typable *H. influenzae*, *M. catarrhalis*, Group A *Streptococcus*, *S. aureus*
- viral: RSV, influenza, parainfluenza, adenovirus
- commonly due to bacterial/viral co-infection

Predisposing Factors
- Eustachian tube dysfunction/obstruction
  - swelling of tubal mucosa
  - upper respiratory tract infection (URTI)
  - allergic rhinitis
  - chronic rhinosinusitis
- obstruction/infiltration of Eustachian tube ostium
  - tumour: nasopharyngeal carcinoma (adults)
  - adenoid hypertrophy (by maintaining a source of infection rather than obstruction)
  - barotrauma (sudden changes in air pressure)
- inadequate tensor palati function: cleft palate (even after repair)
- abnormal Eustachian tube
  - Down syndrome (horizontal position of Eustachian tube), Crouzon syndrome, cleft palate, and Apert syndrome
- disruption of action of:
  - cilia of Eustachian tube: Kartagener’s syndrome
  - mucus secreting cells
  - capillary network that provides humoral factors, PMNs, phagocytic cells
- immunosuppression/deficiency due to chemotherapy, steroids, DM, hypogammaglobulinemia, cystic fibrosis

Risk Factors
- non-modifiable: young age, family history of OM, prematurity, orofacial abnormalities, immunodeficiencies, Down syndrome, race, and ethnicity
- modifiable: lack of breastfeeding, day care attendance, household crowding, exposure to cigarette smoke and air pollution, pacifier use

Pathogenesis
- obstruction of Eustachian tube → air absorbed in middle ear → negative pressure (an irritant to middle ear mucosa) → edema of mucosa with exudate/effusion → infection of exudate from nasopharyngeal secretions

Clinical Features
- triad of otalgia, fever (especially in younger children), and conductive hearing loss
- rarely tinnitus, vertigo, and/or facial nerve paralysis
- otorrhea if tympanic membrane perforated
- infants/toddlers
  - ear-tugging (this alone is not a good indicator of pathology)
  - hearing loss, balance disturbances (rare)
  - irritable, poor sleeping
  - vomiting and diarrhea
  - anorexia
- otoscopy of TM
  - hyperemia
  - bulging, pus may be seen behind TM
  - loss of landmarks: handle and long process of malleus not visible

Clinical Assessment of AOM in Pediatrics
*JAMA* 2010;304:2161-69
In assessment of AOM in pediatrics, ear pain is the most useful symptom with a likelihood ratio (LR) between 3.0-7.3. Useful otoscopic signs include erythema (LR 8.4, 95% CI 7-11), cloudy (LR 51, 95% CI 36-73), and immobile tympanic membrane (LR 31, 95% CI 26-37) on pneumatic otoscopy.
Diagnosis

- **history**
  - acute onset of otalgia or ear tugging in a preverbal child
  - otorrhea, decreased hearing
  - unexplained irritability, fever, upper respiratory symptoms, poor sleeping, anorexia, N/V, and diarrhea
- **physical**
  - febrile
  - MEE on otoscopy: immobile tympanic membrane, acute otorrhea, loss of bony landmarks, opacification of TM, air-fluid level behind TM
- **MEI on otoscopy:** bulging TM with marked discolouration (hemorrhagic, red, grey, or yellow)

Management

- supportive care and symptom management: maintain hydration, analgesic, and antipyretic (acetaminophen, ibuprofen)
- watchful waiting: in a generally healthy child >6 mo of age with unilateral non-severe suspected AOM
  - without MEE, OR with MEE but non-bulging or mildly erythematous TM
  - consider viral etiology
  - reassess in 24-48 h if not clinically improved (or earlier if worsening)
  - mildly ill (alert, responsive, no rigors, mild otalgia, fever <39°C, <48 h illness) with MEE present
  - AND bulging TM
  - recommend analgesia
    - observe and follow-up in 24-48 h – if not improved or worsening, treat with antimicrobials
  - antimicrobials indicated: infants <6 mo of age, or in a generally healthy child >6 mo of age with suspected AOM and the following features
    - moderately or severely ill (irritable, difficulty sleeping, poor antipyretic response, severe otalgia
      OR fever ≥39°C OR >48 h of symptoms
    - treat with antimicrobials: 10 d course if 6-24 mo, 5 d if ≥2 yr old
    - perforated TM with purulent drainage
    - treat with antimicrobials for 10 d
    - referral to otolaryngology for myringotomy and tympanostomy tubes may be warranted for recurrent infections

Treatment

- antimicrobial agents for AOM
  - 5 d course of appropriate dose antimicrobial recommended for most ≥ 2 yr old with uncomplicated AOM.
  - 10 d course for 6-24 mo, and perforated TM or recurrent AOM
  - 1st line treatment (no penicillin allergy)
    - amoxicillin: 5 d course of 45-60 mg/kg/d divided 3x/d, or 75-90 mg/kg/d divided 2x/d
  - 2nd line treatment
    - cefprozil: 30 mg/kg/d divided 2x/d
    - cefuroxime axetil: 30 mg/kg/d divided 2-3x/d (1st line for penicillin allergy)
    - ceftriaxone: 50 mg/kg IM (or IV) x 3 doses (1st line for penicillin allergy)
    - azithromycin: 10 mg/kg OD x 1 dose, then 5 mg/kg OD x 4 doses
    - clarithromycin: 15 mg/kg/d divided 2x/d
  - if initial therapy fails (i.e. no symptomatic improvement after 2-3 d)
    - amoxicillin-clavulanate: 45-60 mg/kg/d (7:1 formulation, 400 mg/5 mL suspension) for 10 d for child weighing ≤35 kg, or 500 mg tablets TID for 10 d for child weighing >35 kg
    - if AOM-related symptoms do not resolve with amoxicillin-clavulanate, a course of ceftriaxone 50 mg/kg/d IM (or IV) OD x 3 doses could be considered

Complications

- extracranial
  - hearing loss and speech delay (secondary to persistent MEE), TM perforation, extension of supplicative process to adjacent structures (mastoiditis, petrositis, labyrinthitis), cholesteatoma, facial nerve palsy, middle ear atelectasis, ossicular necrosis, vestibular dysfunction, persistent effusion (often leading to hearing loss)
- intracranal
  - meningitis, epidural and brain abscess, subdural empyema, lateral and cavernous sinus thrombosis, carotid artery thrombosis, facial nerve paralysis
- other
  - mastoiditis, labyrinthitis, sigmoid sinus thrombophlebitis

Otitis Media with Effusion

Definition

- presence of fluid in the middle ear without signs or symptoms of ear infection

Epidemiology

- most common cause of pediatric hearing loss
- not exclusively a pediatric disease
- frequently follows AOM in children
- middle ear effusions have been shown to persist following an episode of AOM for 1 mo in 40% of children, 2 mo in 20%, and >3 mo in 10% (i.e. 90% of children clear the fluid within 3 mo – observe for 3 mo before considering myringotomy and tubes)
Risk Factors
- same as AOM

Clinical Features
- conductive hearing loss ± tinnitus
  - confirm with audiogram and tympanogram (flat) (see Figure 16B, OT10 and Figure 17B, OT11)
- fullness – blocked ear
  ± pain, low grade fever
- otoscopy of tympanic membrane
  - discoloration – amber or dull grey with "glue" ear
  - meniscus fluid level behind TM
  - air bubbles
  - retraction pockets/TM atelectasis
  - most reliable finding with pneumatic otoscopy is immobility

Treatment
- expectant: 90% resolve by 3 mo
  - watchful waiting for 3 mo from onset, or 3 mo from diagnosis if onset unknown
  - document hearing loss with audiogram
  - no clinical evidence that antihistamines, decongestants, or antibiotics clear disease faster
  - recommend against intranasal or systemic steroids, systemic antibiotics, antihistamines, decongestants for OME treatment
  - surgery: myringotomy ± ventilation tubes to equalize pressure and drain ear (tympanostomy tubes recommended) ± adenoidectomy (not recommended in <4 yr old unless nasal obstruction, chronic adenoiditis; recommended in ≥ 4 yr old)

Complications of Otitis Media with Effusion
- hearing loss, speech delay, learning problems in young children
- chronic mastoiditis
- ossicular erosion
- cholesteatoma, especially when retraction pockets involve pars flaccida
- retraction of tympanic membrane, atelectasis, ossicular fixation

Adenoid Hypertrophy
- size peaks at age 5 and resolves by age 12
- increase in size with repeated URTI and allergies

Clinical Features
- nasal obstruction
  - adenoid facies (open mouth, high arched palate, narrow midface, malocclusion)
  - history of hypernasal voice and snoring
  - long-term mouth breather; minimal air escape through nose
- choanal obstruction
  - chronic rhinosinusitis/rhinitis
  - obstructive sleep apnea
- chronic inflammation
  - nasal discharge, post nasal drip, and cough
  - cervical lymphadenopathy

Diagnosis
- enlarged adenoids on nasopharyngeal exam (usually with flexible nasopharyngoscope)
- enlarged adenoid shadow on lateral soft tissue x-ray

Complications
- Eustachian tube obstruction leading to serous otitis media
  - interference with nasal breathing, necessitating mouth-breathing
- malocclusion
- sleep apnea/respiratory disturbance
- orofacial developmental abnormalities

Adenoidectomy
Indications for Adenoidectomy
- chronic upper airway obstruction with sleep disturbance/apnea ± cor pulmonale
- chronic nasopharyngitis resistant to medical treatment
- chronic serous otitis media and chronic supplicative otitis media (with 2nd set of tubes)
- recurrent acute otitis media resistant to antibiotics
- suspicion of nasopharyngeal malignancy
- persistent rhinorrhea secondary to nasal obstruction
Contraindications
• uncontrollable coagulopathy
• recent pharyngeal infection
• conditions that predispose to velopharyngeal insufficiency (cleft palate, impaired palatal function, or enlarged pharynx)

Complications
• bleeding, infection
• velopharyngeal insufficiency (hypernasal voice or nasal regurgitation)
• scarring of Eustachian tube orifice

Sleep-Disordered Breathing in Children

Definition
• spectrum of sleep-related breathing abnormalities ranging from snoring to OSA

Epidemiology
• peak incidence between 2-8 yr when tonsils and adenoids are the largest relative to the pharyngeal airway

Etiology
• due to a combination of anatomic and neuromuscular factors
  • adenotonsillar hypertrophy
  • craniofacial abnormalities
  • neuromuscular hypotonia (i.e. cerebral palsy, Down syndrome)
  • obesity

Clinical Features
• heavy snoring, mouth breathing pauses or apnea, enuresis, excessive daytime sleepiness, behavioural/learning problems, diagnosis of ADHD, morning headache, failure to thrive, sleeping with neck hyperextended, cyanosis

Investigations
• flexible nasopharyngoscopy for assessment of nasopharynx and adenoids
• polysomnography (apnea-hypopnea index >1/h considered abnormal)
  • children: Mild OSA ≥1 to <5/h; Moderate OSA ≥5 to <10/h; Severe OSA ≥10/h
  • adults: Mild OSA 5.1-15/h; Moderate OSA 15.1-30/h; Severe OSA >30.1/h

Treatment
• nonsurgical: CPAP, BiPAP, sleep hygiene, weight loss in overweight/obese child with OSA
• medication: topical nasal steroids and leukotriene-receptor antagonists for mild OSA or residual sleep-disordered breathing post-adenotonsillectomy
• surgical: bilateral tonsillectomy and adenoidectomy is first surgery of choice
  • if persistent obstructive sleep apnea following tonsillectomy and adenoidectomy, consider adenoid regrowth
  • if these fail and not tolerant of PAP therapy, consider lingual tonsillectomy, midline glossectomy, or other surgeries targeting areas of resistance as required (STAR surgery); surgery may be guided by Drug-Induced Sleep Endoscopy (DISE) or CINE-MRI to localize site of resistance

Acute Tonsillitis
• see Pediatrics, P52

Peritonsillar Abscess (Quinsy)

Definition
• cellulitis of space behind tonsillar capsule extending onto soft palate, leading to abscess

Etiology
• bacterial: Group A strep (GAS) (50% of cases), S. pyogenes, S. aureus, H. influenzae, and anaerobes

Epidemiology
• can develop from acute tonsillitis with infection spreading into plane of tonsillar bed
• unilateral
• most common in 15-30 yr age group

Clinical Features
• trismus (due to irritation and reflex spasm of the medial pterygoid) is the most reliable indicator of peritonsillar abscess
• fever and dehydration
• sore throat, dysphagia, and odynophagia
• extensive peritonsillar swelling but tonsil may appear normal
- edema of soft palate
- uvular deviation
- dysphonia (edema → failure to elevate palate) 2° to CN X involvement
- unilateral referred otalgia
- cervical lymphadenitis

**Complications**
- aspiration pneumonia 2° to spontaneous rupture of abscess
- airway obstruction
- lateral dissection into parapharyngeal and/or carotid space
- bacteremia
- retropharyngeal abscess

**Treatment**
- secure airway
- surgical drainage (incision or needle aspiration) with C&S
- warm saline irrigation
- IV penicillin G x 10 d if cultures positive for GAS
- add PO/IV metronidazole or clindamycin x 10 d if culture positive for Bacteroides
- consider tonsillectomy after second episode

**Other Sources of Parapharyngeal Space Infections**
- pharyngitis
- acute suppurative parotitis (see Salivary Glands, OT30)
- AOM
- mastoiditis (Bezold's abscess)
- odontogenic infection

---

### Tonsillectomy

**Absolute Indications**
- most common indication: sleep-disordered breathing
- 2nd most common indication: recurrent throat infections
- tonsillar hypertrophy causing upper airway obstruction, obstructive sleep apnea, severe dysphagia, or cardiopulmonary complications such as cor pulmonale
- suspicion of malignancy (e.g. lymphoma, squamous cell carcinoma)
- orofacial/dental deformity
- hemorrhagic tonsillitis

**Relative Indications (To Reduce Disease Burden)**
- recurrent throat infection with a frequency of at least 7 episodes in the past year, at least 5 episodes per year for 2 yr, or at least 3 episodes per year for 3 yr, with documentation in the medical record for each episode of sore throat and 1 or more of the following: temperature >38.3 °C, cervical adenopathy, tonsillar exudate, or positive test for Group A β-hemolytic *Streptococcus* (Paradise Criteria)
- chronic tonsillitis with halitosis (bad breath) or sore throat ± tonsilloliths (clusters of material that form in the crevices of the tonsils)
- complications of tonsillitis: quinsy/peritonsillar abscess, parapharyngeal abscess, retropharyngeal abscess
- failure to thrive

**Relative Contraindications**
- velopharyngeal insufficiency: overt or submucous/covert cleft of palate, impaired palatal function due to neurological or neuro-muscular abnormalities
- hematologic: coagulopathy, anemia
- infectious: active local infection without urgent obstructive symptoms

**Complications**
- hemorrhage: primary (within 24 h); secondary (within first 7-10 d)
- odynophagia and/or otalgia; dehydration 2° to odynophagia
- infection
- atlantoaxial subluxation (Grisel's syndrome) - rare

---

### Airway Problems in Children

**DIFFERENTIAL DIAGNOSIS BY AGE GROUP**

**Neonates (Obligate Nose Breeders)**
- extralaryngeal
  - choanal atresia (e.g. CHARGE syndrome)
  - nasopharyngeal dermoid, glioma, encephalocele
  - glossoptosis: Pierre-Robin sequence, Down syndrome, lymphatic malformation, hemangioma
• laryngeal
  ▪ laryngomalacia: most common cause of stridor in children
  ▪ vocal cord palsy (due to trauma or Arnold-Chiari malformation)
  ▪ glottic web
  ▪ subglottic stenosis
  ▪ laryngeal cleft
  ▪ laryngocele
• tracheal
  ▪ tracheoesophageal fistula
  ▪ tracheomalacia
  ▪ vascular rings
  ▪ complete tracheal rings

2-3 Months
• congenital
  ▪ laryngomalacia
  ▪ vascular: subglottic hemangioma (more common), innominate artery compression, double aortic arch
  ▪ laryngeal papilloma
• acquired
  ▪ subglottic stenosis: post-intubation
  ▪ tracheal granulation: post-intubation
  ▪ tracheomalacia: post-tracheotomy and TEF repair

Infants – Sudden Onset
• foreign body aspiration
• croup
• bacterial tracheitis
• caustic ingestion
• epiglottitis

Children and Adults
• infection
  ▪ Ludwig’s angina
  ▪ peritonsillar/parapharyngeal abscess
  ▪ retropharyngeal abscess
• neoplastic
  ▪ squamous cell carcinoma (SCC) (adults): larynx, hypopharynx
  ▪ retropharyngeal: lymphoma, neuroblastoma
  ▪ nasopharyngeal: carcinoma, rhabdomyosarcoma
• allergic
  ▪ angioneurotic edema
  ▪ polyps (suspect cystic fibrosis in children)
• trauma
  ▪ laryngeal fracture, facial fracture
  ▪ burns and lacerations
  ▪ post-intubation
  ▪ caustic ingestion
• congenital
  ▪ lingual thyroglossal duct cyst
  ▪ lingual tonsil hypertrophy
  ▪ lingual thyro de

**Signs of Airway Obstruction**

**Stridor**
• note quality, timing (inspiratory or expiratory)
• body position important
  ▪ lying prone: double aortic arch
  ▪ lying supine: laryngomalacia, glossoptosis
• site of stenosis
  ▪ vocal cords or above: inspiratory stridor
  ▪ subglottis and extrathoracic trachea: biphasic stridor
  ▪ distal tracheobronchial tree: expiratory stridor

**Respiratory Distress**
• nasal flaring
• supraclavicular and intercostal indrawing
• sternal retractions
• use of accessory muscles of respiration
• tachypnea
• cyanosis
• altered LOC
Feeding Difficulty and Aspiration
- supraglottic lesion
- laryngomalacia
- vocal cord paralysis
- laryngeal cleft → aspiration pneumonia
- TEF

Acute Laryngotracheobronchitis (Croup)

Definition
- inflammation of tissues in subglottic space ± tracheobronchial tree
- swelling of mucosal lining and associated with thick, viscous, mucopurulent exudate which compromises upper airway (subglottic space is narrowest portion of upper airway)
- normal function of ciliated mucous membrane impaired

Etiology
- viral: parainfluenzae I (most common), II, III, influenza A and B, RSV

Clinical Features
- age: 4 mo-5 yr
- preceded by URTI symptoms
- generally occurs at night
- biphasic stridor and croupy cough (loud, sea lion bark)
- appear less toxic than epiglottitis
- supraglottic area normal
- rule out foreign body and subglottic stenosis
- "steeple-sign" on AP X-ray of neck
- if recurrent croup, think subglottic stenosis

Treatment
- racemic epinephrine via MDI q1-2h prn (only if in respiratory distress)
- systemic corticosteroids (e.g. dexamethasone 0.5 mg/kg, prednisone)
- adequate hydration
- close observation for 3-4 h
- intubation if severe (use smaller endotracheal tube than expected for age)
- hospitalize if poor response to steroids after 4 h and persistent stridor at rest
- consider alternate diagnosis if poor response to therapy (e.g. bacterial tracheitis)
- if recurrent episodes of croup-like symptoms, perform high kV croup series X-ray (AP and lat) when well to rule out underlying subglottic stenosis and consider bronchoscopy for definitive diagnosis

Acute Epiglottitis

Definition
- acute inflammation causing swelling of supraglottic structures of the larynx without involvement of vocal cords

Etiology
- H. influenzae type b
- relatively uncommon condition due to Hib vaccine

Clinical Features
- any age most commonly 1-4 yr
- rapid onset
- toxic-looking, fever, anorexia, restlessness
- cyanotic/pale, inspiratory stridor, slow breathing, lungs clear with decreased air entry
- prefers sitting up ("tripod" posture), open mouth, drooling, tongue protruding, sore throat, dysphagia

Investigations and Management
- investigations and physical exam may lead to complete obstruction, thus preparations for intubation or tracheotomy must be made prior to any manipulation
- stat ENT/anesthesia consult(s)
- WBC (elevated), blood and pharyngeal cultures after intubation
- lateral neck radiograph (only done if patient stable)

Treatment
- secure airway
- IV access with hydration
- antibiotics: IV cefuroxime, cefotaxime, or ceftriaxone
- moist air
- extubate when leak around tube occurs and afebrile
- watch for meningitis

When managing epiglottitis, it is important not to agitate the child, as this may precipitate complete obstruction

Thumb sign: cherry-shaped epiglottic swelling seen on lateral neck radiograph
Subglottic Stenosis

Congenital
- Diameter of subglottis <4 mm in neonate (due to thickening of soft tissue of subglottic space or maldevelopment of cricoid cartilage)

Acquired
- Following prolonged, repeated, or traumatic intubation
  - Most commonly due to endotracheal intubation; nasal intubation is less traumatic and preferred in long-term intubation, as it puts less pressure on the subglottis (tube sits at different orientation) and there is less movement
  - Subglottic stenosis is related to duration of intubation and pressure of the endotracheal tube cuff
- Can also be due to foreign body, infection (e.g., TB, diphtheria, syphilis), or chemical irritation

Clinical Features
- Biphasic stridor
- Respiratory distress
- Recurrent/prolonged croup

Diagnosis
- Rigid laryngoscopy and bronchoscopy

Treatment
- If soft stenosis: divide tissue with knife or laser, dilate with balloon ± steroids
- If firm stenosis: laryngotracheoplasty

Laryngomalacia

- Short aryepiglottic folds, omega-shaped epiglottis, pendulous mucosa
- Caused by indrawing of supraglottis on inspiration, leading to laryngopharyngeal reflux of acid

Clinical Features
- High-pitched inspiratory stridor at 1-2 wk
- Stridor is constant or intermittent and more pronounced supine and following URTI
- Usually mild but can be associated with cyanosis or feeding difficulties when severe, leading to failure to thrive

Treatment
- Observation ± proton pump inhibitor (to break the acid reflux cycle that leads to edema and worse airway obstruction) is usually sufficient, as symptoms spontaneously subside by 12-18 mo in >90% of cases
- If severe, division of the aryepiglottic folds (supraglottoplasty) provides relief

Foreign Body

Ingested
- Usually stuck at cricopharyngeus muscle
- Coins, toys, batteries (emergency)
- Presents with drooling, dysphagia, stridor if very large

Aspirated
- Usually stuck at right main bronchus
- Peanuts, carrot, apple core, popcorn, balloons
- Presentation
  - Stridor if lodged in trachea
  - Unilateral “asthma” if bronchial, therefore often misdiagnosed as asthma
  - If totally occludes airway: cough, lobar pneumonia, atelectasis, mediastinal shift, pneumothorax, death

Diagnosis and Treatment
- Sudden onset, not necessarily febrile or elevated WBC
- Any patient with suspected foreign body should be kept NPO immediately
- Older patient: inspiratory-expiratory chest X-ray (if patient is stable)
- Younger patient: right and left decubitus chest X-rays. Lack of lung deflation while resting on dependent side suggests foreign body blocking bronchus
- Bronchoscopy or esophagoscopy with removal

Batteries MUST be ruled out as a foreign body (vs. coins) as they are lethal and can erode through the esophagus. Batteries have a halo sign around the rim on AP x-ray and a step deformity on lateral x-ray
**Deep Neck Space Infection**

- most commonly arise from an infection of the mandibular teeth, tonsils, parotid gland, deep cervical lymph nodes, middle ear, or the sinuses
- often a rapid onset and may progress to fatal complications

**Etiology**
- usually mixed aerobes and anaerobes that represent the flora of the oral cavity, upper respiratory tract, and certain parts of the ears and eyes

**Clinical Features**
- sore throat or pain and trismus
- dysphagia and odynophagia
- stridor and dyspnea
- late findings may include dysphonia and hoarseness
- swelling of the face and neck, erythema
- asymmetry of the oropharynx with purulent oral discharge
- lymphadenopathy

**Diagnosis**
- lateral cervical view plain radiograph
- CT
- MRI

**Treatment**
- secure the airway
- surgical drainage
- maximum doses of IV systemic antimicrobials regimens according to the site of infection

3. Growth and Development
4. Nutrition
5. Injury Prevention Counselling

**Common Complaints**

- 8

1. Breath Holding Spells
2. Circumcision
3. Crying/Fussing Child
4. Infantile Colic
5. Dentition and Caries
6. Enuresis
7. Encopresis
8. Toilet Training
9. Failure to Thrive
10. Obesity
11. Poison Prevention
12. Rashes
13. Sleep Disturbances
14. Sudden Infant Death Syndrome

**Child Abuse and Neglect**

- 14

1. Physical Abuse
2. Sexual Abuse
3. Neglect

**Adolescent Medicine**

- 15

**Cardiology**

- 16

1. Congenital Heart Disease
2. Atrioventricular Canal (AVM) Heart Disease
3. Cyanotic Congenital Heart Disease
4. Congestive Heart Failure
5. Dysrhythmias
6. Heart Murmurs
7. Infective Endocarditis

**Development**

- 22

1. Approach to Global Developmental Delay
2. Intellectual Disability
3. Language Delay
4. Specific Learning Disorder
5. Fetal Alcohol Spectrum Disorder
6. Attention Deficit Hyperactivity Disorder
7. Autism Spectrum Disorder
8. Motor Delay

**Endocrinology**

- 25

1. Antidiuretic Hormone
2. Diabetes Mellitus
3. Growth
4. Hypercalciemia/Hypocalciemia/Rickets
5. Hyperthyroidism and Hypothyroidism
6. Sexual Development

**Gastroenterology**

- 32

1. Vomiting
2. Gastroesophageal Reflux
3. Tracheoesophageal Fistula
4. Pyloric Stenosis
5. Duodenal Atresia
6. Malrotation of the Intestine
7. Diarrhea
8. Gastroenteritis
9. Toddler’s Diarrhea
10. Lactase Deficiency (Lactose Intolerance)
11. Irritable Bowel Syndrome
12. Celiac Disease
13. Milk Allergy (MA) and Cow’s Milk Protein Allergy
14. Inflammatory Bowel Disease
15. Cystic Fibrosis
16. Constipation
17. Abdominal Pain
18. Chronic Abdominal Pain
19. Abdominal Mass
20. Upper Gastrointestinal Bleeding
21. Lower Gastrointestinal Bleeding

**Genetics, Dysmorphisms, and Metabolism**

- MG4

1. Congenital Anomalies
2. Approach to the Dysmorphic Child
3. Genetic Syndromes
4. Metabolic Diseases

**Hematology**

- 40

1. Approach to Anemia
2. Physiologic Anemia
3. Iron Deficiency Anemia
4. Vitamin K Deficiency
5. Anemia of Chronic Disease
6. Sickle Cell Disease
7. Thalassemia
8. Hereditary Spherocytosis
9. Glucose-6-Phosphate Dehydrogenase Deficiency
10. Bleeding Disorders
11. Immune Thrombocytopenic Purpura
12. Hemophilia
13. von Willebrand’s Disease

**Oncology**

- 43

1. Lymphadenopathy
2. Leukemia
3. Lymphoma
4. Brain Tumours
5. Wilms’ Tumour (Nephroblastoma)
6. Neuroblastoma
7. Bone Tumours
8. Cancer Predisposition Syndromes

**Infectious Diseases**

- 46

1. Fever
2. Acute Otitis Media
3. Otitis Media with Effusion
4. Gastroenteritis

### Primary Care

#### Visit Overview

- **schedule**
  - newborn (within 1 wk post-discharge), 1, 2, 4, 6, 9, 12, 15, 18, 24 mo
  - annually between age 2-5; every 1-2 years between age 6-18
- **content**
  - history and physical exam including growth, development and nutrition
  - routine immunizations
  - counselling and anticipatory guidance
Routine Immunization

IM = intramuscular; PO = per oral; SC = subcutaneous

Vaccine Adverse Reaction

DTaP-IM
- Prolonged crying
- Hypotonic unresponsive state (rare)
- Seizure on day of vaccine (rare)
- Anaphylactic reaction to neomycin or streptomycin

Rot-IM
- Cough
- Diarrhea, vomiting
- History of intussusception
- Immunocompromised
- Abdominal disorder (e.g. Meckel’s diverticulum)
- Received blood products (e.g. immunoglobulin) within 42 d

MMR
- Measles-like rash (7 14 d)
- Lymphadenopathy, arthralgia, arthritis
- Parotitis (rare)
- Especially painful injection
- Transient thrombocytopenia (1/30,000)

Var
- Mild varicella-like papules or vesicles;
- 2 wk may get local or generalized rash

HepB
- Anaphylactic reaction to Baker’s yeast

MMRV
- Same as MMR and Var vaccines

dTAP
- 1st trimester pregnancy

Inf
- Malaria, myalgia
- Febrile seizure when given with Pneu-C 13 or DTap

HPV-4*
- Urticaria, rhinitis, anaphylaxis

MenB**
- Anaphylactic reaction to MenB vaccine or its components in the past

Contraindication

- Evolving unstable neurologic disease
- Hyporesponsive/hypotonic following previous vaccine
- Anaphylactic reaction to neomycin or streptomycin
- History of intussusception
- Immunocompromised
- Abdominal disorder (e.g. Meckel’s diverticulum)
- Immunocompromised infants (except healthy HIV positive children)
- Anaphylactic reaction to gelatin
- Pregnancy
- Immunocompromised infants
- Healthy HIV positive children
- Anaphylactic reaction to gelatin
- Pregnant or planning to get pregnant within 3 mo
- Anaphylactic reaction to gelatin
- 1st trimester pregnancy
- <6 mo of age
- Immunocompromised
- Egg-allergic individuals – Live attenuated influenza vaccine is not recommended for those with an egg allergy. In these individuals, trivalent or quadrivalent vaccine can be given in environment where anaphylaxis can be managed

Vaccination in Cases of Asplenia or Hypersensitivity

- Should receive all routine immunizations, including the yearly influenza vaccine
- No vaccines are contraindicated
- Susceptible to infection by encapsulated bacteria (“SHINE KISS” – S. pneumoniae, H. influenzae, N. meningitidis, E. coli, Klebsiella, Salmonella, Group B Strept)
- Must add:
  - Meningococcal-C-Conjugate at age ≥2 yr
  - Quadravalent Men-P-ACYW at least 2 wk later
- Booster of Men-P-ACYW at age ≥2 y
- Pneumococcal polysaccharide vaccine (Pneu-P-23) at age ≥2 y
- Single booster of Pneu-P-23 at age ≥3 yr
- Consider single booster HiB at age ≥5 y

Growth and Development

Growth
- Growth is not linear
- Most rapid growth during first 2 yr and at puberty
- Tissues grow at different times
  - First 2 yr = CNS; mid-childhood = lymphoid tissue; puberty = gonads
- Measurement of growth
  - Premature infants (<37 wk) use corrected GA until age 2
  - Body proportion = upper/lower segment ratio (use symphysis pubis as midpoint)
  - Newborn = 1.7, adult male = 0.9, adult female = 1.0

Injection site
- Infants (<12 mo): anterolateral thigh
- Children (≥12 mo): anterolateral thigh

* ** Males 9-26 yrs: Currently only publically funded for men who have sex with men
** Current only publically funded for select groups (asplenia, antibody/complement deficiencies, coch ear implant recipients, HIV, close contacts with infected individuals)

Adverse Reactions Associated With Any Vaccine

- Local: induration, tenderness, redness, swelling
- Systemic: fever, rash, instability
- Allergic: urticaria, rhinitis, anaphylaxis
- Contraindications
- Moderate/severe illness
- Allergy to vaccine component
- No need to delay vaccination for mild URTI

According to the CDC, the weight of currently available scientific evidence does not support the hypothesis that MMR vaccine causes autism or IBD. The landmark paper linking autism to the MMR vaccine (Lancet 1998;351:637-641) was retracted due to false claims in the article (Lancet 2010;375:445)
Average Growth Parameters

Table 3. Parameter of Average Growth at Birth

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Normal</th>
<th>Growth</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Birth Weight</td>
<td>3.25 kg (7 lbs)</td>
<td>Gain 20-30 g/d (term neonate)</td>
<td>Weight loss (up to 10% of birth weight) in first 7 d of life is normal. Neonate should regain birth weight by ~10-14 d of age.</td>
</tr>
<tr>
<td>Length/Height</td>
<td>50 cm (20 in)</td>
<td>25 cm in 1st yr, 12 cm in 2nd yr, 8 cm in 3rd yr then 4-7 cm/yr until puberty</td>
<td>Measure supine length until 2 yr of age, then measure standing height.</td>
</tr>
<tr>
<td>Head Circumference</td>
<td>35 cm (14 in)</td>
<td>2 cm/mo for 1st mo, 1 cm/mo at 3-6 mo, 0.5 cm/mo at 6-12 mo</td>
<td>Measure around occipital, parietal, and frontal prominences to obtain the greatest circumference.</td>
</tr>
</tbody>
</table>

Reflexes

Table 4. Reflexes

<table>
<thead>
<tr>
<th>Reflex</th>
<th>Maneuver to Elicit Reflex</th>
<th>Appropriate Reflex Response</th>
<th>Age of Disappearance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Moro</td>
<td>Infant placed semi-upright, head supported by examiner’s hand, sudden withdrawal of supported head with immediate return of support</td>
<td>Abduction and extension of the arms, opening of the hands, followed by flexion and adduction of arms</td>
<td>4-6 mo</td>
</tr>
<tr>
<td>Galant</td>
<td>Infant held in ventral suspension and one side of back is stroked along paravertebral line</td>

Safety and Efficacy of an Attenuated Vaccine Against Severe Rotavirus Gastroenteritis

Methods: Randomized, double-blind, phase 3 trial including healthy infants from Latin America and Finland, assigned to receive two oral doses of HRV vaccine versus placebo at 2 and 4 mo of age. Primary outcomes were episodes of gastrointestinal symptoms and severity. Results: 63,225 healthy infants were enrolled. The vaccine was 85% efficacious against severe rotavirus gastroenteritis and hospitalizations associated with gastroenteritis (p<0.001) and 100% efficacious against more severe gastroenteritis. Hospitalization for diarrhea of any cause was reduced by 42% (95% CI -29.53%, p=0.001). Six vaccine recipients and seven placebo recipients had definite intussusception within 31 d after each dose (risk difference -0.32/10,000 infants; 95% CI -2.91 to 2.18, p=0.78).

Conclusion: Two oral doses of the live attenuated HRV vaccine were highly efficacious in decreasing incidence of severe rotavirus and all-cause gastroenteritis, and were not associated with an increased risk of intussusception.
Nutrition

Dietary Requirements

<td>1,500 cal + 20 kcal/kg/d for each kg &gt;20</td>
<td></td>
</tr>
</tbody>
</table>

Dietary Recommendations

- 0-6 mo: breast milk or formula
  - exclusive breast milk during first 6 mo recommended over formula unless contraindicated
  - breastfed infants require supplements: vitamin D (400 IU/d), fluoride (after 6 mo if not sufficient in water), iron (6-12 mo, only if not receiving fortified cereals/meat/meat alternatives)
- >6 mo: solid food introduction – do not delay beyond 9 mo
- 2-3 new foods per wk, wait at least 2 d in between each food to allow time for adverse reaction identification
  - common allergens: eggs, milk, mustard, peanuts, seafood, seaweed, soy, tree nut, wheat
- early introduction of highly allergenic foods is recommended
- offer lumpy, soft-cooked, pureed, mashed textured foods
- 9-24 mo: switch to homogenized (3.25%) milk, offer 16 oz/d to non-breastfeeding infant
- offer vegetables, fruit, grains, and full-fat milk in any order after iron-rich foods are given
- provide up to 3 large feedings (meals) with 1-2 smaller feedings (snacks), depending on child’s hunger/satiety cues
- encourage self-feeding and introduce open cup (should be done by 18 mo)
- foods to avoid
  - honey until past 12 mo (risk of botulism)
  - added sugar, salt
  - excessive milk (i.e. no more than 750 mL or 24 oz/d after 1 yr)
  - limit juice intake (not nutritious, too much sugar), maximum 4-6 oz (1/2 cup) daily anything that is a choking hazard (chunks, round foods like grapes)
  - 2-6 yr: switch to 2% milk (500 mL/day)
  - can maintain breastfeeding during this time complementary to solids

Breastfeeding

- content of breast milk
  - colostrum (first few days): clear, rich in nutrients (i.e. high protein, low fat), immunoglobulin
  - mature milk: 70:30 whey:casein ratio, fat from dietary butterfat, carbohydrate from lactose
- advantages
  - easily digested, low renal solute load
  - immunologic
    - contains IgA, macrophages, active lymphocytes, lysozymes, lactoferrin (which inhibits E. coli growth in intestine)
    - lower pH promotes growth of Lactobacillus in GI tract

Table 5. Developmental Milestones (continued)

<table>
<thead>
<tr>
<th>Age*</th>
<th>Gross Motor</th>
<th>Fine Motor</th>
<th>Speech and Language</th>
<th>Adaptive and Social Skills</th>
</tr>
</thead>
<tbody>
<tr>
<td>15 mo</td>
<td>Walks without support, crawls up stairs/steps</td>
<td>Picks up and eats finger foods, scribbles, stacks 2 blocks</td>
<td>4-5 words, points to needs/wants</td>
<td>Looks to see how others react (e.g. after falling)</td>
</tr>
<tr>
<td>18 mo</td>
<td>Runs, walks forward pulling toys or carrying objects</td>
<td>Tower of 3 cubes, scribbling, eats with spoon</td>
<td>10 words, follows simple commands</td>
<td>Shows affection towards others, points to show interest in something</td>
</tr>
<tr>
<td>24 mo</td>
<td>Climbs up and down steps with 2 feet per step, runs, kicks ball</td>
<td>Tower of 6 cubes, undresses</td>
<td>2-3 word phrases, uses &quot;I, me, you&quot;, 50% intelligible, understands 2-step commands</td>
<td>Parallel play, helps to dress</td>
</tr>
<tr>
<td>3 yr</td>
<td>Rides tricycle, climbs up 1 foot per step, down 2 feet per step, stands on one foot briefly</td>
<td>Copies a circle, turns pages one at a time, puts on shoes, dress/undress fully except buttons</td>
<td>Combines 3 or more words into sentence, recognizes color, numbers, prepositions, plurals, counts to 10, 75% intelligible</td>
<td>Knows sex and age, shares some of the time, plays make-believe games</td>
</tr>
<tr>
<td>4 yr</td>
<td>Hops on 1 foot, climbs down 1 foot per step</td>
<td>Copies a cross, uses scissors, buttons clothes</td>
<td>Speech 100% intelligible, uses past tense, understands 3-part directions</td>
<td>Cooperative play, fully toilet-trained by day, tries to comfort someone who is upset</td>
</tr>
<tr>
<td>5 yr</td>
<td>Skips, rides bicycle</td>
<td>Copies a triangle and square, prints name, ties shoelaces</td>
<td>Fluent speech, future tense, alphabet, retells sequence of a story</td>
<td>Cooperates with adult requests most of the time</td>
</tr>
</tbody>
</table>
- parent-child bonding
- economical, convenient
- maternal contraindications
  - chemotherapy or radioactive compounds
  - HIV/AIDS, active untreated TB, herpes in breast region
  - >0.5 g/kg/d of alcohol or illicit drugs
  - medications known to cross to breast milk
  - OCPs are not a contraindication to breastfeeding (estrogen may decrease lactation, but is not dangerous to infant)
  - MotherRisk® Program – valuable research and counselling on reproductive risk or safety of drugs and chemicals
- breastfeeding jaundice (first 1-2 wk): due to lack of maternal milk production and subsequent infant dehydration (see jaundice, P69)
- breast milk jaundice (0.3% of newborns, persists up to 4-6 mo): rare, glucuronyl transferase inhibitor in breast milk inhibits conjugation of bilirubin, increases enterohepatic circulation of bilirubin
  - baby presents healthy and thriving, and jaundice (secondary to unconjugated bilirubin) resolves
- poor weight gain: consider dehydration or FIT
- oral candidiasis (thrush): treat baby with antifungal such as nystatin; can occur in breast or bottle-fed infants

</table>

Note: This list is not exhaustive. For more details, see Rourke Baby Record (http://www.rourkebymbrecord.ca/pdf/RBR2011Ont_Eng.pdf)
**Breath Holding Spells**

- epidemiology: 0.1-5% of healthy children 6 mo-4 yr of age, usually start during first year of life
- etiology: child is provoked (usually by anger, injury, or fear) → holds breath and becomes silent → spontaneously resolves or loses consciousness
- types
  - cyanotic (more common), usually associated with anger/frustration
  - pallid, usually associated with pain/surprise
- management
  - usually resolves spontaneously and rarely progresses to seizure
  - help child control response to frustration and avoid drawing attention to spell
  - may be associated with iron deficiency anemia, improves with supplemental iron

**Circumcision**

- elective procedure
  - not covered by OHIP in Ontario, but recent evidence shows show risks vs. benefit → not clearly different; no clear position by CPS in 2015 statement
  - often for religious or culture reasons
  - beneficial: prevention of phimosis and slightly reduced incidence of UTI, STI, balanitis, cancer of the penis
  - complications (<1%): local infection, bleeding, urethral injury
  - contraindications: presence of genital abnormalities (e.g. hypospadias) or known bleeding disorder

**Crying/Fussing Child**

- history
  - description of baseline feeding, sleeping, crying patterns
  - infectious symptoms: fever, tachypnea, rhinorrhea, ill contacts
  - feeding intolerance: gastroesophageal reflux with esophagitis, N/V, diarrhea, constipation
  - trauma
  - recent immunizations (vaccine reaction) or medications (drug reactions), including maternal drugs taken during pregnancy (neonatal withdrawal syndrome) and drugs that may be transferred via breast milk
  - inconsistent history, pattern of numerous emergency department visits, high-risk social situations all raise concern of maltreatment

**Table 8. Physical Exam and Differential Diagnosis**

</tr>
</tbody>
</table>

**Infantile Colic**

- definition: unexplained paroxysms of irritability and crying for ≥3 h/d, ≥3 d/wk for ≥3 wk in an otherwise healthy, well-fed baby (rule of 3s)
- epidemiology: 10% of infants; usual onset 10 d to 3 mo of age with peak at 6-8 wk
- etiology: unknown. Theories: alterations in fecal microflora, cow’s milk intolerance, GI immaturity or inflammation, poor feeding, maternal smoking
Common Complaints

- diagnosis of exclusion: rule out otitis media, cow's milk intolerance, GI problem, fracture

**management**
- parental relief, rest, and reassurance
- hold baby, soother, car ride, music, vacuum, check diaper
- some evidence for probiotics
- maintain breastfeeding but eliminate allergens (cow's milk protein, eggs, wheat and nuts) from mother's diet
- try casein hydrolysate formula (Nutramigen®)
- time – all resolve, most in the first 3-6 mo of life, no long-term adverse effects

**Dentition and Caries**

**Dentition**
- primary dentition (20 teeth)
  - first tooth at 5-9 mo (lower incisor), then 1/mo
  - 6-8 central teeth by 1 yr
  - assessment by dentist 6 mo after eruption of first tooth and certainly by 1 yr of age (Grade B recommendation)
- secondary dentition (32 teeth)
  - first adult tooth is 1st molar at 6 yr, then lower incisors

**Caries**
- milk caries: decay of superior front teeth and back molars in first 4 yr of life
- cause: often due to prolonged feeding (e.g. put to bed with bottle, prolonged breastfeeding)
- prevention
  - no bottle at bedtime, clean teeth after last feed
  - minimize juice and sweetened pacifier
  - clean teeth with soft damp cloth or toothbrush and water
  - water fluoridation

**Enuresis**

**Definition**
- involuntary urinary incontinence by day and/or night in child >5 yr

**General Approach**
- should be evaluated if dysuria, change in colour, odour, stream, secondary or diurnal, change in gait, stool incontinence

**Primary Nocturnal Enuresis**
- definition: involuntary loss of urine at night, bladder control has never been attained
- epidemiology: boys > girls; 10% of 6 yr olds, 3% of 12 yr olds, 1% of 18 yr olds
- etiology: developmental disorder or maturational lag in bladder control while asleep
- management
  - time and reassurance (~20% resolve spontaneously each yr)
  - behaviour modification (limiting fluids, voiding prior to sleep), bladder retention exercises, scheduled toileting overnight has limited effectiveness
  - conditioning: "wet" alarm wakes child upon voiding (70% success rate)
  - medications (for children >7 yr, considered second line therapy, may be used for sleepovers/camp): DDAVP oral tablets (similar success rate as "wet" alarm therapy but higher relapse rate), imipramine ('Tofranil®') (rarely used, lethal if overdose, SE: cardiac toxicity, anticholinergic effects)

**Secondary Enuresis**
- definition: involuntary loss of urine at night, develops after child has sustained period of bladder control (>6 mo)
- etiology: inorganic regression due to stress or anxiety (e.g. birth of sibling, significant loss, family discord, sexual abuse), secondary to organic disease (UTI, DM, DI, sleep apnea, neurogenic bladder, CP, seizures, pinworms)
- management: treat underlying cause

**Diurnal Enuresis**
- definition: daytime wetting (60-80% also wet at night)
- etiology: micturition deferral (holding urine until last minute) due to psychosocial stressor (e.g. shy), structural anomalies (e.g. ectopic ureteral site, neurogenic bladder), UTI, constipation, CNS disorders, DM
- management: treat underlying cause, behavioural (scheduled toileting, double voiding, good bowel program, sitting backwards on toilet, charting/incentive system, relaxation/biofeedback), pharmacotherapy

**Antidiuretic Hormone Regulation in Primary Nocturnal Enuresis**

**Arch Dis Child** 1995;73(6):508-11

**Purpose:** To evaluate the efficacy of DDAVP for the treatment of primary nocturnal enuresis.

**Methods:** Children with primary nocturnal enuresis were compared with a corresponding control group. Diurnal and nocturnal urine production, ADH secretion, and plasma osmolality were determined.

**Results:** Ten children (mean age 10.5 years) with primary nocturnal enuresis were compared to a control group of eight patients. No differences in urine production, ADH levels during day and night, or plasma osmolality were found. However, the enuretic children required a markedly greater ADH output (2.87 pg/ml/mmol/kg vs. 0.56 in controls; p<0.01).

**Conclusion:** ADH secretion is a function of plasma osmolality. Urine production is not increased at night in individuals with primary nocturnal enuresis because of lower ADH secretion.

**Treatment for primary nocturnal enuresis**

should not be considered until 7 yr of age due to high rate of spontaneous cure
**Encopresis**

- **definition** fecal incontinence in a child >4 yr old, at least once per mo for 3 mo
- **prevalence**: 1-1.5% of school-aged children (rare in adolescence); M:F = 6:1 in school-aged children
- **causes**: chronic constipation (retentive encopresis), Hirschsprung disease, hypothyroidism, hypercalcemia, spinal cord lesions, anorectal malformations, bowel obstruction

**Retentive Encopresis**

- **definition**: child holds bowel movement develops constipation, leading to fecal impaction and seepage of soft or liquid stool (overflow incontinence)
- **etiology**
  - physical: painful stooling often secondary to constipation
  - emotional: disturbed parent-child relationship, coercive toilet training, social stressors
- **clinical presentation**
  - history
    - crosses legs or stands on toes to resist urge to defecate
    - distressed by symptoms, soiling of clothes
    - toilet training coercive or lacking in motivation
    - may show oppositional behaviour
    - abdominal pain
  - physical exam
    - digital rectal exam or abdo x-ray: large fecal mass in rectal vault
    - anal fissures (result from passage of hard stools)
  - palpable stool in LLQ
- **management**
  - complete clean-out of bowel: PEG 3350 given orally is most effective, enemas and suppositories may be second line therapies, but these are invasive and often less effective
  - maintenance of regular bowel movements (see Constipation Treatment, P36)
  - assessment and guidance regarding psychosocial stressors
  - behavioural modification
- **complications**: recurrence, toxic megacolon (requires >3-12 mo to treat) bowel perforation

**Toilet Training**

- 90% of children attain bladder control before bowel control
- generally, females train earlier than males
- 25% by 2 yr (in North America), 98% by 3 yr have daytime bladder control
- signs of toilet readiness
  - ambulating independently, stable on potty, desire to be independent or to please caregivers (i.e. motivation), sufficient expressive and receptive language skills (2-step command level), can stay dry for several h (large enough bladder), can recognize need to go, able to remove clothing

**Failure to Thrive**

- **definition** weight <3rd percentile, falls across two major percentile curves, or <80% of expected weight for height and age
- inadequate caloric intake most common factor in poor weight gain
- may have other nutritional deficiencies (e.g. protein, iron, vitamin D)
- factors affecting physical growth: genetics, intrauterine factors, nutrition, endocrine hormones, chronic infections/diseases, psychosocial factors
- **clinical presentation**
  - history
    - nutritional intake
    - current symptoms
    - past illnesses
    - family history: growth, puberty, parental height and weight including mid-parental height
    - psychosocial history
  - physical exam
    - growth parameters, plotted: height, weight, head circumference, arm span
    - vital signs
    - complete head to toe exam
    - dysmorphic features or evidence of chronic disease
    - upper to lower segment ratio
    - sexual maturity staging
    - signs of maltreatment or neglect
- **investigations** (as indicated by clinical presentation)
  - CBC, blood smear, electrolytes, T4, TSH
  - bone age x-ray
  - chromosomes/karyotype
  - chronic illness: chest (CXR, sweat Cl–), cardiac (CXR, ECG, Echo), GI (celiac screen, inflammatory markers, malabsorption), renal (urinalysis), liver (enzymes, albumin)

**Mid-Parental Height**

- Boys target height = (father ht + mother ht + 13) / 2
- Girls target height = (father ht + mother ht - 13) / 2
- **Note**: height should be taken in cm

**Clinical Signs of FTT**

- **SMALL KID**
  - Subcutaneous fat loss
  - Muscle atrophy
  - Alopecia
  - Lethargy
  - Lagging behind normal
  - Kwashiorkor
  - Infection (recurrent)
  - Dermatitis

</tbody>
</table>

BA = bone age; CA = chronological age; HC = head circumference; Ht = height; Wt = weight

Etiology
- an interplay between pathophysiology and psychosocial influences. Investigations should assess:
  - complex factors in the parent-child relationship
    - dietary intake, knowledge about feeding, improper mixing of formula
    - feeding environment
    - parent-child interaction, attachment
    - child behaviours, hunger/satiety cues
    - postpartum depression
    - social factors: stress, poverty, neglect, child/domestic abuse, parental substance abuse, restricted diets
  - inadequate caloric intake: inadequate milk supply/latching, mechanical feeding difficulty (cleft palate), oromotor dysfunction, toxin-induced anorexia
  - inadequate absorption: biliary atresia, celiac, IBD, CF; inborn errors of metabolism, milk protein allergy, pancreatic cholestatic conditions
  - increased metabolism: chronic infection, CF, lung disease from prematurity, hyperthyroidism, asthma, IBD, malignancy, renal failure

Management
- most as outpatient using multidisciplinary approach: primary care physician, dietitian, psychologist, social work, CAS
- medical: oromotor problems, iron-deficiency anemia, gastro-esophageal reflux
- nutritional: educate about age-appropriate foods, calorie boosting, mealtime schedules and environment; goal to reach 90–110% IBW, correct nutritional deficiencies, and promote catch-up growth/development
- behavioural: positive reinforcement, mealtime environment

Energy Requirements
- see Nutrition, P6

Obesity
- definition: overweight is BMI >85th percentile; obesity is BMI >95th percentile for age and height
- risk factors: genetic predisposition (e.g. both parents obese – 80% chance of obese child)
- etiology: organic causes are rare (<5%), but may include Prader-Willi, Carpenter, Turner, Cushing syndromes, hypothyroidism
- complications: association with HTN, dyslipidemia, slipped capital femoral epiphysis, type 2 DM, asthma, obstructive sleep apnea, gynecostasia, polycystic ovarian disease, early menarche, irregular menses, psychological trauma (e.g. bullying, decreased self-esteem, unhealthy coping mechanisms, depression)
- childhood obesity often persists into adulthood
- investigations: BP pulse, screen lipid profile
- management:
  - encouragement and reassurance; engagement of entire family
  - diet: qualitative changes (do not encourage weight loss, but allow for linear growth to catch up with weight), special diets used by adults and very low calorie diets are not encouraged
  - behaviour modification: increase activity, change eating habits/meal patterns, limit juice/sugar drinks, ensure adequate sleep
  - education: multidisciplinary approach, dietitian, counselling
  - surgery and pharmacotherapy are rarely used in children
  - increase physical activity (1 h/d), reduce screen time (<2 h/d)
  - in children with risk factors/complications: AST/ALT and diabetes screening, small changes in energy expenditure and intake (lose 1 lb/mo)
  - long term goal: maintain BMI <85th percentile

Poison Prevention
- keep all types of medicines, vitamins, and chemicals locked up in a secure container
- potentially dangerous: medications, illicit drugs, drain cleaners, furniture polish, insecticides, cosmetics, nail polish remover, automotive products
- do not store any chemicals in juice, soft drink, or water bottles
- keep alcoholic beverages out of reach: 3 oz hard liquor can kill a 2 yr old
- always read labels before administering medicine to ensure correct medication drug and dose and/or speak with a pharmacist or healthcare provider

Pediatric Exanthems (see Infectious Pediatric Exanthems, P50)

Drug Reactions (see Dermatology, D21)

Acne (see Dermatology, D11)

Sleep Disturbances

Types of Sleep Disturbances

- insufficient sleep quantity
  - difficulty falling asleep (e.g. limit setting sleep disorder)
  - preschool and older children
  - bedtime resistance
  - due to caregiver’s inability to set consistent bedtime rules and routines
  - often exacerbated by child’s oppositional behaviours

- poor sleep quality
  - frequent arousals (e.g. sleep-onset association disorder)
  - infants and toddlers
  - child learns to fall asleep only under certain conditions or associations (e.g. with parent, held, rocked or fed, with light on, in front of television), and loses ability to self-soothe
  - during the normal brief arousal periods of sleep (q90-120 min), child cannot fall back asleep because same conditions are not present

- obstructive sleep apnea
- epidemiology: 1-5% of preschool aged children, more common in African American children
- definition: partial or intermittent complete airway obstruction during sleep causing disrupted ventilation and sleep pattern
- features: snoring/gasping/noisy breathing during sleep and irritable/tired/hyperactive during the day
- sequelae: cardiovascular (HTN/LV remodelling due to sympathetic activation), growth, cognitive, and behavioural deficits

Daily Sleep Requirement

- <6 mo: 16 h
- 6 mo: 14.5 h
- 12 mo: 13.5 h
- 2 yr: 13 h
- 4 yr: 11.5 h
- 6 yr: 9.5 h
- 12 yr: 8.5 h
- 18 yr: 8 h

Nap Patterns

- 2/d at 1 yr
- /d at 2 yr: 2-3 h
- 0.5/d at 5 yr: 1.7 h
Common Complaints

- risk factors: adenotonsillar hypertrophy, craniofacial abnormalities, obesity
- investigation: polysomnography is gold standard for diagnosis but not required (expensive, inaccessible)
- management: adenotonsillectomy and weight management are first-line tx, follow-up for residual OSA. Watchful waiting acceptable in mild-moderate cases
  - adenotonsillectomy does not improve executive function/attention but improves behaviour, QOL, polysomnographic findings
  - use CPAP if adenotonsillectomy is contraindicated (cleft palate/bleeding disorder/acute tonsillitis), OSA w/ minimal adenotonsillar tissue, residual OSA
  - avoid pollutants/tobacco smoke, allergens
  - avoid use of corticosteroids and antibiotics
- parasomnias
  - episodic nocturnal behaviours (e.g. sleepwalking, sleep terrors, nightmares)
  - often involves cognitive disorientation and autonomic/skeletal muscle disturbance

Management of Sleep Disturbances

- set strict bedtimes and "wind-down" routines
- do not send child to bed hungry
- positive reinforcement for: limit setting sleep disorder
- always sleep in own bed, in a dark, quiet, and comfortable room
- do not use bedroom for timeouts
- systematic ignoring and gradual extinction for: sleep-onset association disorder

Nightmares

- epidemiology: common in boys, 4-7 yr old
- associated with REM sleep (anytime during night)
- features: upon awakening, child is alert and clearly recalls frightening dream ± associated with daytime stress/anxiety
- management: reassurance

Night Terrors

- epidemiology: 15% of children have occasional episodes
- abrupt sitting up, eyes open, screaming
- clinical features: occurs in early hours of sleep, stage 4 of sleep; signs of panic and autonomic arousal, no memory of event, inconsolable, stress/anxiety can aggravate them
- course: remits spontaneously at puberty
- management: reassurance for parents, ensure child is safe (e.g. if sleepwalks)

Sudden Infant Death Syndrome

Definition

- sudden and unexpected death of an infant <12 mo of age in which the cause of death cannot be found by history, examination, or a thorough postmortem and death scene investigation

Epidemiology

- 0.5/1,000 (leading cause of death between 1-12 mo of age); M:F = 3:2
- more common in children placed in prone position
- in full term infants, peak incidence is 2-4 mo, 95% of cases occur by 6 mo
- increase in deaths during peak RSV season
- most deaths occur between midnight and 8 AM

Risk Factors

- prematurity (<37 wk), early bed sharing (<12 wk), alcohol use during pregnancy, soft bedding, low birthweight, bed sharing, Aboriginals ethnicity, male, no prenatal care, smoking in household, prone sleep position, poverty
- risk of SIDS is increased 3-5x in siblings of infants who have died of SIDS
- bedsharing: sleeping on a sofa, sleeping with an infant after consumption of alcohol/street drugs or extreme fatigue, sleeping on a surface with a fixed wall (couch/sofa), infant sleeping with someone other than primary caregiver

Prevention

- "Back to Sleep, Front to Play" (place infant on back when sleeping)
- avoid sharing bed with infant
- allow supervised play time daily in prone position ("tummy time")
- alarms, monitors not recommended – increase anxiety, do not prevent life-threatening events
- avoid overheating and overdressing
- appropriate infant bedding (firm mattress, avoid loose bedding, pillows, stuffed animals, and crib bumper pads)
- no smoking
- exclusive breastfeeding in first mo
- pacifiers appear to have a protective effect; do not reinsert if falls out during sleep
- infant monitors do not reduce incidence

Brief Resolved Unexplained Events (BRUE)

A group of conditions often marked by an episode of apnea, cyanosis, change in tone, or change in mental status occurring in a child, when an observer fears the child may be dying. There is no clear connection between most BRUEs and SIDS. Evaluating for a cause of the BRUE (e.g. infection, cardiac, neurologic) is guided by history, physical exam, and period of observation
# Child Abuse and Neglect

**Definition**
- an act of commission (physical, sexual, or psychological abuse) or omission (neglect) by a caregiver that harms a child

**Legal Duty to Report**
- upon reasonable grounds to suspect abuse and/or neglect, physicians are required by legislation to contact the CAS to personally disclose all information relevant to the child safety concern
- duty to report overrides patient confidentiality; physician is protected against liability

**Ongoing Duty to Report**
- if there are additional reasonable grounds to suspect abuse and/or neglect, a further report to the CAS must be made

**Risk Factors**
- environmental factors: social isolation, poverty, domestic violence
- caregiver factors: personal history of abuse, psychiatric illness, postpartum depression, substance abuse, single parent family, poor social and vocational skills, below average intelligence
- child factors: difficult temperament, disability, special needs (e.g. developmental delay), premature

**Management of Physical Abuse, Child Abuse, and Neglect**
- report all suspicions to CAS; request emergency visit if imminent risk to child or any siblings in the home
- acute medical care: hospitalize for medical evaluation or treatment of injuries if indicated
- arrange consultation to social work and appropriate follow-up
- may need to discharge child directly to CAS or to responsible guardian under CAS supervision

---

## Physical Abuse

**History**
- history that is not compatible with physical findings or with child's developmental capabilities
- history not reproducible or changes dramatically over time
- delay in seeking medical attention that is unexplained by other factors
- assess previous trauma or hospitalizations
- ask FHx: bleeding disorder, bone disorder, metabolic conditions
- ask developmental history

**Physical Exam**
- physical findings not explained by underlying medical condition
- growth parameters including past recorded parameters (weight, height, head circumference)
- multiple injuries not explained by accidental injury or child's development level
- patterned skin injuries: belt buckle, hand prints, burns that do not match provided history
- injury location: bruises; on areas with abundant soft-tissue cushioning, such as abdomen, buttocks, genitalia, fleshy part of cheek or on ears, neck or feet; fractures; posterior rib/metaphyseal/scapular/vertebral/sternal fractures (more suspicious for non-accidental injuries); bruises that do not fit described cause; immersion burns (e.g. hot water)
- altered mental status: head injury, poisoning
- eyes – retinal hemorrhages
- scalp – patchy hair loss from traumatic alopecia or severe malnutrition
- oral exam – check the frenula for tears
- head trauma is the leading cause of death in child maltreatment (e.g. acceleration-deceleration forces [shaking], direct force application [blow or impact])
- consider “red herrings” (e.g. slate grey macule/congenital dermal melanocytosis vs. bruises)

**Investigations**
- document all injuries on a body diagram: type, location, size, shape, colour, pattern
- photography of skin injuries is ideal (police or hospital photography preferred; do not use physician’s personal camera)
- rule out medical causes of bruising/fracture with appropriate investigations (e.g. blood disorders or rickets):
  - if fractures evident: Ca++, Mg++, PO43-, ALP, PTH, Vitamin D, albumin
  - if bruising present: CBC, INR, PT, von Willebrand factor, factors VIII/IX
- screen for abdominal trauma
  - transaminases and amylase if elevated: abdo CT recommended
  - renal function – electrolytes, urinalysis
    - toxicity screen – overdose or poisoning
- skeletal survey in children <2 yr; select imaging based on history in children >5 yr
- neuroimaging: CT and/or MRI - dilated eye examination by pediatric ophthalmologist to rule out retinal haemorrhage if subdural hemorrhage detected on head imaging

---

**Medical Assessment of Bruising in Suspected Child Maltreatment Cases**

Paediatr Child Health 2013;18(8):433-7
CPS Position Statement: While bruises are most often due to minor accidental injury, they may also signal underlying medical illness or inflicted injury. Knowing when to assess bruises in the context of maltreatment can be challenging. The following are red flags for inflicted injury in such bruising cases:
- Babies not yet cruising
- Present on ears, neck, feet, buttocks or torso
- Not on the front of the body and/or overlying bone
- Unusually large or numerous
- Clustered or patterned
- Not fitting with the described causal mechanism
Sexual Abuse

Epidemiology
- peak ages at 2-6 yr and 12-16 yr, most do not report until adulthood
- as adults: more likely to develop obesity, sexual problems, IBS, fibromyalgia, STI, substance use disorder.
  More likely to experience intimate partner violence and sexual assault
- in decreasing order: family member, non-relative known to victim, stranger

History
- do not take a sexual abuse history from a young child; this must be done by trained personnel (e.g. during a forensic interview)
- psychosocial: specific or generalized fears, depression, nightmares, social withdrawal, lack of trust, low self-esteem, school failure, sexually aggressive behaviour, advanced sexual knowledge, sexual preoccupation or play

Physical Exam
- recurrent UTIs, pregnancy, STIs, vaginitis, vaginal bleeding, pain, genital injury, enuresis
  - anogenital exam performed along with head-to-toe physical for physical trauma
  - instrumentation not required for anogenital exam, speculum contraindicated in prepubertal girls
  - most victims have normal anogenital exam – cannot rule out sexual abuse if exam is negative

Investigations
- depend on presentation, age, sex, and pubertal development of child
  - sexual assault examination kit within 24 h if prepubertal, within 72 h if pubertal
  - rule out STI, UTI, pregnancy (consider STI prophylaxis or emergency contraception)
  - rule out other injuries (vaginal/anal/oral penetration, fractures, head trauma)
  - investigations to rule out drug and alcohol screen e.g. Rohypnol, 'Liquid G,' etc.

Neglect

Definition
- omissions in care by parents or caregiver that leads in actual or potential harm

History
- from child and each caregiver separately (if possible)

Physical Exam
- head to toe (do not force), growth parameters, nutrition status
  - dental care
  - emotional state

Investigations
- blood tests to rule out medical conditions (e.g. thrombocytopenia or coagulopathy)

Adolescent Medicine

Adolescent History (HEEADSSS)
- tailor your history according to the clinical context

Home: Who do you live with? What kind of place do you live in? Do you get along with your parents and/or siblings?

Education/Employment: What grade are you in? What are your favourite subjects? What was your average on your last report card (ask for changes)? How much school have you missed this past year? Do you work (if so, how much)? Do you get along with teachers/employers?

Eating: Tell me about your meals/snacks in a typical day. Have you ever gone on a diet? What are your favourite and least favourite foods? (see Psychiatry, Eating Disorders, PS30)

Activities: What do you do after school? On the weekends? How much time do you spend on the computer/watching TV every day? Do you use social media (i.e. Facebook, Twitter, Instagram, etc.)? What do you do with your friends outside of school?

Drugs: Which seems to be more popular at your school, alcohol or drugs? How often do you drink/smoke marijuana take other drugs? Do you smoke cigarettes? When you drink, do you usually get drunk? Have you ever passed out or not been able to remember what happened while you were drinking? Has anything bad ever happened to you while you were drunk or stoned? (see Psychiatry, Substance Abuse, PS21)
Sexuality: Are you romantically interested in anyone? When you think about having sex with someone, do you think about females, males, or both? Have you ever had sex with anyone? Whether the answer is yes or no, the next question is: What activities would you include in the term ‘having sex’? What do you do to prevent getting a STI/getting pregnant/getting someone pregnant? Has anyone ever given you money, drugs, or other stuff in exchange for sex? (see Gynecology, Sexually Transmitted Infections, GY27)

Suicidality/Depression: On a scale of 1 to 10, where 1 is so sad that you might kill yourself and 10 is the happiest you could be, where are you most days? Have you lost interest in activities that you used to enjoy? Do you often have trouble sleeping (Is there a difference between school days and the weekend)? Have you ever thought seriously about suicide? Did you make a plan? (see Psychiatry, Depression/Suicide, PS10, PS4)

Safety/Violence: Do you ever get into a car with a driver who has been drinking? Do you always wear a seatbelt/bicycle helmet? Are you being bullied at school? Has anyone ever touched you in an unwanted way?

See Normal and Abnormal Pubertal Development, P30

Cardiology

Congenital Heart Disease

PRENATAL CIRCULATION

Before Birth
- shunting deoxygenated blood
  - ductus arteriosus: connection between pulmonary artery and aorta
  - shunting oxygenated blood
  - foramen ovale: connection between right and left atria
  - ductus venosus: connection between umbilical vein and inferior vena cava

At Birth
- with first breath, lungs open up → pulmonary resistance decreases → pulmonic blood flow increases
- separation of low resistance placenta → systemic circulation becomes a high resistance system → ductus venosus closure
- increased pulmonic flow → increased left atrial pressures → foramen ovale closure
- increased oxygen concentration in blood after first breath → decreased prostaglandins → ductus arteriosus closure
- closure of fetal shunts and changes in vascular resistance → infant circulation assumes normal adult flow

Epidemiology
- 8/1,000 live births have CHD, which may present as a heart murmur, heart failure, or cyanosis; VSD is the most common lesion
**Investigations**
- Echo, ECG, CXR
- pre and postductal oxygen saturations, 4 limb BPs, hyperoxia test

**CYANOTIC VS. ACYANOTIC CONGENITAL HEART DISEASE**
- cyanosis: blue mucous membranes, nail beds, and skin secondary to an absolute concentration of deoxygenated hemoglobin of at least 30 g/dL
- acyanotic heart disease (i.e. L to R shunt, obstruction occurring beyond lungs): blood passes through pulmonic circulation → oxygenation takes place → low levels of deoxygenated blood in systemic circulation → no cyanosis
- cyanotic heart disease (i.e. R to L shunt): blood bypasses the lungs → no oxygenation occurs → high levels of deoxygenated hemoglobin enters the systemic circulation → cyanosis

**Figure 2. Common congenital heart diseases**

### Acyanotic Congenital Heart Disease

1. **LEFT-TO-RIGHT SHUNT LESIONS**
   - extra blood is displaced through a communication from the left to the right side of the heart → increased pulmonary blood flow → increased pulmonary pressures
   - shunt volume is dependent upon three factors: (1) size of defect, (2) pressure gradient between chambers or vessels, and (3) peripheral outflow resistance
   - untreated shunts can result in pulmonary vascular disease, left ventricular dilatation and dysfunction, right ventricular HTN and RVH, and ultimately R to L shunts

   **Atrial Septal Defect**
   - 3 types: *ostium primum* (common in DS), *ostium secundum* (most common type, 50-70%), *sinus* *venous* (defect located at entry of superior vena cava into right atrium)
   - **epidemiology:** 6-8% of congenital heart lesions, common in patients with certain congenital disorders (e.g. Down’s syndrome, fetal alcohol syndrome)
   - **natural history**
     - 80-100% spontaneous closure rate if ASD diameter <8 mm
     - if remains patent, CHF and pulmonary HTN can develop in adult life
   - **clinical presentation**
     - history: often asymptomatic in childhood
     - physical exam: grade 2-3/6 pulmonic outflow murmur, widely split and fixed S2
     - children with large ASDs may have signs of heart failure (tachypnea, FTT, hepatomegaly, pulmonary rales/retractions)
   - **investigations**
     - ECG: RAD, mild RVH, RBBB
     - CXR: increased pulmonary vasculature, cardiac enlargement
     - Echo: test of choice
   - **management:** elective surgical or catheter closure between 2-5 yr of age

   **Ventricular Septal Defect**
   - most common congenital heart defect (30-50%)
   - small VSD (majority)
     - **clinical presentation**
       - history: asymptomatic, normal growth and development
       - physical exam: early systolic to holosystolic murmur, best heard at LLSB, thrill
     - **investigations:** ECG and CXR are normal; Echo to confirm diagnosis
     - **management:** most close spontaneously
   - moderate-to-large VSD
     - epidemiology: CHF by 2 mo; late secondary pulmonary HTN if left untreated
     - **clinical presentation**

### Cyanotic (5 “T” lesions)

</tbody>
</table>

**Characteristic CXR Findings in CHD**
- Boot-shaped heart: tetralogy of Fallot, tricuspid atresia
- Egg-shaped heart: transposition of great arteries
- “Snowman” heart: total anomalous pulmonary venous return

**Figure 2. Common congenital heart diseases**

- **Moderate-to-Large VSD**
  - Size of VSD is inversely related to intensity of murmur
• history: delayed growth, decreased exercise tolerance, recurrent URTIs or “asthma” episodes
• physical exam: holosystolic murmur at LLSB, mid-diastolic rumble at apex, size of VSD is inversely related to intensity of murmur

• investigations
  • ECG: LVH, LAH, RVH
  • CXR: increased pulmonary vasculature, cardiomegaly, CHF
  • Echo: diagnostic

• management: treatment of CHF and surgical closure by 1 yr old

Patent Ductus Arteriosus

• patent vessel between descending aorta and left pulmonary artery (normally, functional closure within first 15 h of life, anatomical closure within first days of life)

• epidemiology
  • 5–10% of all congenital heart defects
  • delayed closure of ductus is common in premature infants (1/3 of infants <1,750 g); this is different from PDA in term infants
  • natural history: spontaneous closure common in premature infants, less common in term infants

• clinical presentation
  • history: asymptomatic, or have apneic or bradycardic spells, poor feeding, accessory muscle use, CHF
  • physical exam: tachycardia, bounding pulses, hyperactive precordium, wide pulse pressure, continuous “machinery” murmur best heard at left infraclavicular area

• investigations
  • ECG: may show left atrial enlargement, LVH, RVH
  • ECHO is diagnostic
  • CXR: normal to mildly enlarged heart, increased pulmonary vasculature, prominent pulmonary artery

• management
  • indomethacin (Indocid®): antagonizes prostaglandin E2, which maintains ductus arteriosus patency; only effective in premature infants
  • catheter or surgical closure if PDA causes respiratory compromise, FTT, or persists beyond 3rd mo of life

2. OBSTRUCTIVE LESIONS

• present with decreased urine output, pallor, cool extremities and poor pulses, shock, or sudden collapse

Coarctation of the Aorta

• definition: narrowing of aorta (almost always at the level of the ductus arteriosus)

• epidemiology: commonly associated with bicuspid aortic valve (50%); Turner syndrome (35%)

• clinical presentation
  • history: often asymptomatic
  • physical exam
    • blood pressure discrepancy between upper and lower extremities (increased suspicion/severity if >20 mmHg difference)
    • diminished or delayed femoral pulses relative to brachial (i.e. brachial-femoral delay)
    • possible systolic murmur with late peak at apex, left axilla, and left back
    • if severe, presents with shock in the neonatal period when the ductus arteriosus closes

• investigations: ECG shows RVH early in infancy, LVH later in childhood; Echo or MRI for diagnosis

• prognosis: can be complicated by HTN; if associated with other lesions (e.g. PDA, VSD) can lead to CHF

• management: give prostaglandins to keep ductus arteriosus patent for stabilization and perform surgical correction in neonates; for older infants and children balloon arterioplasty may be an alternative to surgical correction

Aortic Stenosis

• 4 types: valvar (75%), subvalvar (20%), supravalvar, and idiopathic hypertrophic subaortic stenosis (5%)

• clinical presentation
  • history: often asymptomatic, but may be associated with CHF, exertional chest pain, syncope, or sudden death
  • physical exam: SEM at RUSB with aortic ejection click at the apex (only for valvar stenosis)

• investigations: Echo for diagnosis

• management: valvar stenosis is usually treated with balloon valvuloplasty, patients with subvalvar or supravalvar stenosis require surgical repair; exercise restriction required

Pulmonary Stenosis

• 3 types: valvar (90%), subvalvar, or supravalvar

• definition of critical pulmonary stenosis: inadequate pulmonary blood flow, dependent on ductus for oxygenation, progressive hypoxia and cyanosis

• natural history: may be part of other congenital heart lesions (e.g. Tetralogy of Fallot) or in association with syndromes (e.g. congenital rubella, Noonan syndrome)

• clinical presentation
  • history: spectrum from asymptomatic to CHF
  • physical exam: wide split S2 on expiration, SEM at LUSB, pulmonary ejection click (for valvar lesions)

• investigations
  • ECG findings: RVH
  • CXR: post-stenotic dilatation of the main pulmonary artery (due to high velocity jet past stenotic valve)
  • Echo: diagnostic

• management: surgical repair if critically ill or if symptomatic in older infants/children
Cyanotic Congenital Heart Disease

- Systemic venous return re-enters systemic circulation directly
- Most prominent feature is cyanosis (O2 sat <75%)
- Hypoxic test differentiates between cardiac and other causes of cyanosis
  - Obtain preductal, right radial ABG in room air, then repeat after the child inspires 100% O2
  - If PaO2 improves to greater than 150 mmHg, cyanosis less likely cardiac in origin
- Pre-ductal and post-ductal pulse oximetry
  - >5% difference suggests R to L shunt

1. RIGHT-TO-LEFT SHUNT LESIONS

Tetralogy of Fallot
- Epidemiology: 10% of all CHD, most common cyanotic heart defect diagnosed beyond infancy with peak incidence at 2-4 mo of age
- Pathophysiology
  - Embryological defect due to anterior and superior deviation of the outlet septum leading to: VSD, RVOTO (i.e. pulmonary stenosis ± subpulmonary valve stenosis), over-riding aorta, and RVH
  - Infants may initially have a L → R shunt (therefore no cyanosis); however, RVOTO is progressive, leading to increasing R → L shunting with hypoxemia and cyanosis
  - Degree of RVOTO determines the direction and degree of shunt and, therefore, the extent of clinical cyanosis and degree of RVH
- Clinical presentation
  - History: Hypoxic "tet" spells
    - During exertional states (crying, exercise) the increasing pulmonary vascular resistance and decrease in systemic resistance causes an increase in right-to-left shunting
  - Clinical features include paroxysms of rapid and deep breathing, irritability and crying, increasing cyanosis, decreased intensity of murmur (decreased flow across RVOTO)
  - If severe, can lead to decreased level of consciousness, seizures, death
- Physical exam
  - Single loud S2 due to severe pulmonary stenosis (i.e. RVOTO), SEM at LSB
- Investigations
  - ECG: RAD, RVH
  - CXR: Boot-shaped heart, decreased pulmonary vasculature, right aortic arch (in 20%)
  - Echo: Diagnostic
- Management of spells
  - O2, knee-chest position, fluid bolus, morphine sulfate, propranolol
  - Treatment: Surgical repair at 4-6 mo of age; earlier if marked cyanosis or "tet" spells

2. OTHER CYANOTIC CONGENITAL HEART DISEASES

Transposition of the Great Arteries (TGA)
- Epidemiology: 3-5% of all congenital cardiac lesions, most common cyanotic CHD in neonates
- Pathophysiology: Parallel pulmonary and systemic circulations
  - Systemic: Body → RA → RV → aorta → body
  - Pulmonary: Lungs → LA → LV → pulmonary artery → lungs
- Survival is dependent on mixing through PDA, ASD, or VSD
- Physical exam
  - Neonates: Ductus arteriosus closure causes rapidly progressive severe hypoxemia unresponsive to oxygen therapy, acidosis, and death
  - VSD present: Cyanosis is not prominent; CHF within first weeks of life
  - VSD absent: No murmur
- Investigations
  - ECG: RAD, RVH, or may be normal
  - CXR: Egg shaped heart with narrow mediastinum ("egg on a string")
  - Echo: Diagnostic
- Management
  - Symptomatic neonates: prostaglandin E1 infusion to keep ductus open until balloon atrial septostomy
  - Surgical repair: arterial switch performed in the first two weeks in those without a VSD while LV muscle is still strong

Total Anomalous Pulmonary Venous Return
- Epidemiology: 1-2% of CHD
- Pathophysiology
  - All pulmonary veins drain into right-sided circulation (systemic veins, RA)
  - No direct oxygenated pulmonary venous return to left atrium
  - Often associated with obstruction at connection sites
  - ASD must be present for oxygenated blood to shunt into the LA and systemic circulation
- Management: Surgical repair in all cases and required urgently for severe cyanosis
Truncus Arteriosus
- **pathophysiology**
  - single great vessel gives rise to the aorta, pulmonary and coronary arteries
  - truncal valve overlies a large VSD
  - potential for coronary ischemia with fall in pulmonary vascular resistance
- **management**: surgical repair within first 6 wk of life

Hypoplastic Left Heart Syndrome
- **epidemiology**: 1-3% of CHD; most common cause of death from CHD in first mo of life
- **pathophysiology**: LV hypoplasia may include atretic or stenotic mitral and/or aortic valve, small ascending aorta, and coarctation of the aorta with resultant systemic hypoperfusion
- systemic circulation is dependent on ductus patency; upon closure of the ductus, infant presents with circulatory shock and metabolic acidosis
- **management**
  - intubate and correct metabolic acidosis
  - IV infusion of prostaglandin E1 to keep ductus open
  - surgical palliation (overall survival 50% to late childhood) or heart transplant

# Congestive Heart Failure
- see Cardiology and Cardiac Surgery, C34

## Etiology
- CHD
- cardiomyopathy (primary or secondary)
- high output circulatory states (e.g. anemia, AVMs, cor pulmonale, hyperthyroidism)
- non-cardiac (e.g. sepsis, renal failure)
- pressure overload (e.g. aortic stenosis/co-arctation, pulmonary stenosis, HTN)
- volume overload (e.g. L to R shunt, valve insufficiency)

## History
- infant: weak cry, irritability, feeding difficulties, early fatigability, diaphoresis while sleeping or eating, respiratory distress, lethargy, FTT
- child: decreased exercise tolerance, fatigue, decreased appetite, respiratory distress, frequent URTIs or “asthma” episodes
- orthopnea, paroxysmal nocturnal dyspnea, pedal/dependent edema are all uncommon in children

## Physical Findings
- 4 key features: tachycardia, tachypnea, cardiomegaly, hepatomegaly
- FTT
- alterations in peripheral pulses, four limb blood pressures (in some CHDs)
- dysmorphic features associated with congenital syndromes

## Investigations
- CXR: cardiomegaly, pulmonary venous congestion
- ECG: sinus tachycardia, signs of underlying cause (heart block, atrial enlargement, hypertrophy, ischemia/infarct)
- Echo: structural and functional assessment
- blood work: CBC, electrolytes, BUN, Cr, LFTs

## Management
- general: sit up, O₂, sodium and water restriction, increased caloric intake
- pharmacologic: diuretics, afterload reduction (e.g. ACEI), β-blockers; digoxin rarely used
- curative: correction of underlying cause

# Dysrhythmias
- see Cardiology and Cardiac Surgery, C16
- can be transient or permanent, congenital (structurally normal or abnormal), or acquired (toxin, infection, infarction)

## Sinus Arrhythmia
- phasic variations with respiration (present in almost all normal children)

## Sinus Tachycardia
- rate of impulses arising from sinus node is elevated (>150 bpm in infants, >100 bpm in older children)
- characterized by beat-to-beat heart rate variability with changes in activity, P waves present/normal, PR constant, QRS narrow
- etiology: HTN, fever, anxiety, sepsis, anemia/hypoxia, PE, drugs, etc.
- differentiate from SVT (see below) by slowing the sinus rate (vagal massage, β-blockers) to identify sinus P waves

Pediatric vs. Adult ECG
Pediatric ECG findings that may be normal:
- HR >100 bpm
- Shorter PR and QT intervals and QRS duration
- Inferior and lateral small Q waves
- RV la ger than LV in neonates, so normal to have:
  - RAD
  - Large precordial R waves
  - Upright T waves
  - Inverted T waves in the anterior precordial leads from early infancy to teen years
Premature Atrial Contractions
• may be normal variant or can be caused by electrolyte disturbances, hyperthyroidism, cardiac surgery, digitalis toxicity

Premature Ventricular Contractions
• common in adolescents
• benign if single, uniform, disappear with exercise, and no associated structural lesions
• if not benign, may degenerate into more severe dysrhythmias

Supraventricular Tachycardia
• abnormally rapid heart rhythm originating above the ventricles – most frequent sustained dysrhythmia in children
• no beat-to-beat HR variability, >220 bpm (infants) or >180 bpm (children), P waves absent/abnormal, PR indeterminable, QRS usually narrow
• pre-excitation syndromes (subset of SVT): WPW syndrome, congenital defect (see Cardiology and Cardiac Surgery, C21)

Complete Heart Block
• congenital heart block can be caused by maternal anti-Ro or anti-La (e.g. mother with SLE)
• often diagnosed in utero (may lead to development of fetal hydrops)
• clinical symptoms related to level of block (the lower the block, the slower the heart rate and greater the symptoms of inadequate cardiac output)
• symptomatic patients need a pacemaker

Heart Murmurs
• 50-80% of children have audible heart murmurs at some point in their childhood
• most childhood murmurs are functional (e.g. “innocent”) without associated structural abnormalities and have normal ECG and radiologic findings
• in general, murmurs can become audible or accentuated in high output states (e.g. fever, anemia)

Infective Endocarditis
• see Infectious Diseases, ID16
Development

Approach to Global Developmental Delay

- a so known as Early Developmental Impairment

Definition
- performance significantly below average in two or more domains of development (gross motor, fine motor, speech/language, cognitive, social/personal, activities of daily living) in a child <5 yr of age
- predict a diagnosis of intellectual disability in the future

Epidemiology
- 5-10% of children have neurodevelopmental delay
- careful evaluation can reveal a cause in 50-70% of cases

Etiology
- CNS abnormalities (meningitis/encephalitis, brain malformation, trauma, etc.)
- sensory deficits (hearing, vision)
- environmental (psychosocial neglect, lead exposure, antenatal drug or alcohol exposure, etc.)
- genetic/chromosomal disorders (DS, Fragile X, etc.)
- metabolic disorders (inborn errors of metabolism, hypothyroidism, iron deficiency, etc.)
- obstetrical (prematurity, HIE, TORCH infections, etc.)
- sleep disorders
- seizures

Clinical Presentation
- history
  ■ prenatal - intrauterine exposures (infections, alcohol), prenatal diagnosis,
  ■ obstetrical – complications, APGAR, infections, seizures, screening
  ■ pediatric - detailed developmental milestones: rate of acquisition, regression of skills
  ■ associated problems: feeding, seizures, behaviour, sleep
  ■ ototoxic antibiotics, frequently ear infections
  ■ family history, consanguinity
  ■ social history
- physical exam
  ■ micro/macrocephaly, dysmorphic features head-to-toe, hepatosplenomegaly, height and weight,
  detailed neurological examination
- investigations (guided by history and physical examination)
  ■ neurodevelopmental assessment, neuroimaging, vision and hearing test, EEG, sleep study
  ■ OT, PT, and/or SLP assessments
  ■ psychosocial evaluation
  ■ blood work (lead, CBC, ferritin, TSH)
  ■ metabolic screening (glucose, electrolytes, lactate, ammonia, liver function, pyruvate, albumin,
  triglycerides, uric acid, amino acids, urine organic acids, acylcarnitines, creatine phosphokinase)
  ■ neurologic – EEG or head CT
  ■ genetics consultation (microarray, Fragile X testing, testing for inborn errors of metabolism)

Management
- dependent on specific area of delay
- therapy services (e.g. speech and language therapy for language delay, OT and/or PT for motor delay),
  early intervention services (e.g. infant development services, Ontario Early Years Centres)

Intellectual Disability

Definition
- state of functioning that begins in childhood and is characterized by limitations in both intelligence and
  adaptive skills
- historically defined as an IQ <70
- often preceded by diagnosis of global developmental delay

Epidemiology
- 1% of general population; M:F = 1.5:1

Clinical Presentation
- history
  ■ earlier age of onset correlates with greater severity of ID
  ■ well below average general intellectual functioning
  ■ significant deficits in adaptive functioning in at least 2 of: communication, self-care, home-living,
  social skills, self-direction, academic skills, work, leisure, health, safety
- physical exam
  ■ check growth, dysmorphic features, complete physical exam

<table>

<td>&lt;20</td>
</tr>
</tbody>
</table>
• investigations
  ■ standard zed psychology assessment (includes IQ test and measure of adaptive functioning)
  ■ vision, hearing, and neurologic assessment
  ■ genetic and metabolic testing as indicated

Management
• main objective: enhance adaptive functioning level
• requires an interprofessional team with strong case coordination
• emphasize community-based treatment and early intervention
• individual/family therapy, behaviour management services, therapy services (e.g. OT, SLP), medications
  for associated conditions
• education: life skills, vocational training, communication skills, family education
• psychosocial support for individual and family; respite care

Prognosis
• higher rates of sensory deficits, motor impairment, behavioural/emotional disorders, seizures,
  psychiatric illness

**Language Delay**

Definition
• no universally accepted definition, but often identified around 18 mo of age with enhanced well baby visit
• if formally tested, at least one standard deviation below mean of age on standardized testing
• can be expressive (ability to produce or use language), receptive (ability to understand language), or both

Epidemiology
• M>F
• ~10-15% of 2 yr old children have a language delay, but only 4-5% remain delayed after 3 yr of age
• ~6-8% of school-aged children have specific language impairment (many of whom were not identified
  before school entry)

Etiology
• intellectual disability
• developmental disorders - cerebral palsy, Autism Spectrum Disorder
  ■ constitutional language delay
  ■ genetic/metabolic: DS, Fragile X syndrome, Williams syndrome, hypothyroidism, PKU, etc.
  ■ mechanical problems: cleft palate, cranial nerve palsy, hearing impairment
  ■ medical condition: seizure disorder (includes acquired epileptic aphasia), CP, TORCH infection, iron
    deficiency, lead poisoning, etc.
  ■ psychosocial: neglect or abuse
  ■ selective mutism
  ■ language specific learning disorder
  ■ isolated language delay

Clinical Presentation
• history
  ■ concerns about hearing, delay in language development or regression in previously normal language
  development
  ■ delayed language milestones, presence of red flags, regression (see Table 5 Developmental Milestones)
  ■ must determine if language delay is expressive, receptive, or mixed
  ■ determine differences in behaviour at home, school, other social environments
  ■ risk factors: family history of speech and language delay, male, prematurity, low birth weight, hearing loss
• physical exam
  ■ guided by history; look for abnormal growth, dysmorphisms unusual social interactions (lack of eye
    contact not pointing)
  ■ include full exam of the external/internal ear (e.g. TM scarring), oral pharynx (e.g. cleft palate), and
    neurologic system (including tone)
• investigations
  ■ use of language specific screens in primary care setting: The Early Language Milestone
  ■ CAT/CLAMS, MCHAT, etc.
  ■ developmental evaluation
  ■ referred to an audiologist if hearing loss is suspected
  ■ CBC (to rule out anemia), venous blood lead levels, genetic/metabolic workup as indicated

Management
• specific to etiology
• often interdisciplinary and requires appropriate referrals: early intervention services, special education
  services, SLP, OHNS and dental professionals, general support services
• prevention: parents can read aloud to their child, engage in dialogic reading, avoid baby talk, narrate
  daily activities, etc.

Prognosis
• depends on etiology – best prognosis for developmental speech delay
• if language delay persists beyond 5 yr old, more likely to have difficulties in adulthood
• persistent language delay is associated with poor academic performance, behavioural problems, social
  isolation
Specific Learning Disorder

Definition
- specific and persistent failure to acquire academic skills despite conventional instruction, adequate intelligence, and sociocultural opportunity
- a significant discrepancy between a child's intellectual ability and their academic performance
- types: reading (dyslexia), writing, mathematics (dyscalculia)

Epidemiology
- prevalence: 10%
- high incidence of psychiatric comorbidity: anxiety, dysthymia, conduct disorder, major depressive disorder, oppositional defiant disorder, ADHD

Etiology
- pathogenesis is unknown, likely genetic factors involved
- learning disabilities may be associated with a number of conditions:
  - genetic/metabolic: Turner syndrome, Klinefelter syndrome
  - perinatal: prematurity, low birth weight, birth trauma/hypoxia
  - postnatal: CNS damage, hypoxia, environmental toxins, FAS, psychosocial deprivation (understimulation), malnutrition
- poor visual acuity is NOT a cause

Risk Factors
- positive family history, prematurity, other developmental and mental health conditions, neurologic disorders (e.g. seizure disorders, neurofibromatosis), history of CNS infection/irradiation/traumatic injury

Clinical Presentation
- history and physical exam
  - school difficulties (academic achievement, behaviour, attention, social interaction, over-reliance on teacher)
  - development of negative self-concept → reluctance to participate even in areas of strength
  - social issues: overt hostility towards parents/teachers; difficulties making friends, bullying, and anxiety
  - look for dysmorphism, complete physical exam
- investigations
  - psychoeducational assessment
  - individual scores on achievement tests in reading, mathematics, or written expression (WISC III WRAT) >2 SD below that expected for age, education, and IQ
  - evaluate child's attention, memory, expressive language, coordination skills

Management
- provide quality instruction for specific learning disability
- support student by modifying the curriculum and/or providing accommodations (e.g. scribe for writing, extra time for tests, photocopied notes, etc.)
- consider grade retention in certain students (no guidelines exist, very rare in Ontario)
- specialized education placements that can provide educational remediation

Prognosis
- limited information available about persistence of learning disabilities over time
- low self-esteem, poor social skills, 40% school drop-out rate

Fetal Alcohol Spectrum Disorder

Definition
- term describing the range of effects of prenatal exposure to alcohol, including physical, mental behavioural, and learning disabilities
- abstinence from alcohol during pregnancy is recommended
- spectrum includes: FAS, partial FAS, ARBD (alcohol related brain damage) and ARND (alcohol related neurodevelopmental disorder)

Epidemiology
- prevalence of FAS and FASD is 0.1% and 1.0%, respectively
- most common preventable cause of intellectual disability

Pathogenesis
- specific mechanism of FASD is unknown, but hypotheses include nutritional deficits, toxic effects of acetaldehyde, alteration of placental transport, abnormal protein synthesis, and altered cerebral neurotransmission
Diagnosis
- often misdiagnosed or missed entirely
- diagnosis of FAS, ARBD, and ARND all require evidence of maternal drinking during pregnancy
- criteria for diagnosis of FAS
  - growth deficiency: low birth weight and/or decelerating weight over time not due to nutrition
  - characteristic pattern of facial anomalies: short palpebral fissures (<2SD below mean), flattened philtrum, thin upper lip (having all 3 features is highly specific for alcohol exposure, don't need maternal history to confirm)
  - CNS dysfunction (need ≥3): motor skills; neuroanatomy/neuropsychology; cognition; language; academic achievement; memory; attention; executive function (impulse control and hyperactivity); affect regulation; adaptive behaviour, social skills or social communication OR microcephaly in infant and young children
- criteria for diagnosis of ARBD
  - congenital anomalies, including malformations and dysplasias of the cardiac, skeletal, renal, ocular, and auditory systems
- criteria for diagnosis of ARND
  - CNS dysfunction (similar to FAS)
  - complex pattern of behavioural or cognitive abnormalities inconsistent with developmental level that cannot be explained by familial background or environment alone

Management
- early diagnosis is essential to prevent secondary disabilities
- no cure, but individuals with FASD and their families should be linked to community resources and services to improve outcome

Prognosis
- secondary disabilities include unemployment, mental health problems, difficulties with the law, inappropriate sexual behaviour, disrupted school experience, peer problems

Attention Deficit Hyperactivity Disorder
- see Psychiatry, Neurodevelopmental Disorders, PS38

Autism Spectrum Disorder
- see Psychiatry, Neurodevelopmental Disorders, PS37

Motor Delay
- see Cerebral Palsy, P83 and Medical Genetics, Duchenne Muscular Dystrophy, MG7

Endocrinology

Diabetes Insipidus
- see Endocrinology, E18 and Nephrology, NP11

Syndrome of Inappropriate Antidiuretic Hormone
- see Endocrinology, E18 and Nephrology, NP10

Diabetes Mellitus

DIABETES MELLITUS TYPE 1
- see Endocrinology, Disorders of Glucose Regulation, E6

Epidemiology
- most common form of DM in children, M=F
- variable prevalence internationally, affects ~1-4,000 children in Canada
- can present at any age, but bimodal peaks at 5-7 yr old and at puberty

Clinical Presentation
- can present as polyuria (often manifested as nocturia or secondary enuresis), polydipsia, weight loss (lack of insulin leading to a catabolic state), polyphagia, DKA (~20%) (see Endocrinology, E11)
Management

- patients and families are best managed with a family-centred pediatric multidisciplinary team able to provide education, ongoing care, and psychosocial support surrounding survival skills, meal plans, and insulin injections as a cornerstone of treatment
- diet with consistent levels of carbohydrates, avoiding foods with high glycemic index is advised
- exercise recommended, extensive activity involving legs (walking, cycling, running) may cause prolonged hypoglycemia
- administer influenza immunization yearly to avoid complications to management
- blood glucose monitoring is especially important in children as they are more susceptible to hypoglycemia
- administer glucagon or dextrose for severe hypoglycemia
- if DKA present: ABCs, 100% O2, admit, monitors, correct fluid losses, conduct ECG (assess abnormal T waves), administer insulin and restore glucose gradually (first SC and then IV if no improvement), correct electrolyte disturbances, identify/treat precipitating event, avoid complications (i.e. cerebral edema)
- low threshold to investigate (CT/MRI) and treat DKA, as cerebral edema is a major concern
- signs of neurological deterioration – headache, bradycardia, irritability, decrease LOC, incontinence, specific neurological signs)
- administer mannitol for cerebral edema
- frequent BG, fluid and electrolyte monitoring
- see Endocrinology, E11

screen for micro- and macrovascular complications (regular ophthalmology assessments, BP, microalbuminuria), concurrent autoimmune diseases (thyroiditis, celiac disease, etc.), and mental health issues (depression, eating disorders), hypertension, dyslipidemia

Prognosis

- no cure currently
- short-term complications
  - hypoglycemia
  - due to missed/delayed meals, excess insulin or exercise, illness
  - can lead to seizures and/or coma
  - reversed with PO/IV glucose or IM glucagon
  - hyperglycemia
  - due to intercurrent illness, diet-to-insulin mismatch
  - risk of end-organ damage
  - DKA: due to missed insulin doses, infection; most common cause of death
- long-term complications
  - microvascular: retinopathy, nephropathy, neuropathy
  - macrovascular: metabolic syndrome, CVD, CAD, PVD
  - increased risk of other autoimmune diseases
  - hypertension, dyslipidemia

DIABETES MELLITUS TYPE 2

- see Family Medicine, FM22, and Endocrinology, E7
- impaired glucose metabolism due to increased peripheral insulin resistance
- rare before 10 yr of age, but more common in older children/adolescents
- prevalence is rising mainly due to the increased incidence of childhood obesity
- risk factors: obesity, positive family history, female gender, PCOS, hyperglycemia exposure in utero, certain ethnic groups
- risk reduced with breastfeeding
- clinical presentation may be similar to that of type 1 DM, though most children are asymptomatic
- may present in DKA or hyperglycemic hyperosmotic nonketotic state
- investigation – fasting plasma glucose recommended, oral glucose tolerance test for very obese children with multiple risk factors
- management
  - insulin used for severe metabolic decompensation at diagnosis (DKA, A1C > 9%), can wean off
  - initiate lifestyle modification program, including diet, weight loss, physical activity (moderate-to-vigorous activity for at least 60 min/d; screen time less than 2 h/d)
  - glycemic target: HbA1c ≤7%
  - if glycemic targets not achieved within 3-6 mo from diagnosis with lifestyle intervention alone, either metformin (first line), glimepiride, or insulin should be initiated
  - metformin can be initiated at diagnosis if HbA1c >7%
  - monitor HbA1c every 3 mo
  - advise patient to monitor finger-stick blood glucose levels if on medication with risk of hypoglycemia, are changing medication regimen, have not met treatment goals, or have intercurrent illness
  - screening – same as T1D plus annual screening for PCOS and NAFLD
- prognosis: includes microvascular and macrovascular complications similar to type 1 DM

Growth (see FTT)

APPROACH TO SHORT STATURE

Definition

- short stature: height <3rd percentile
- poor growth evidenced by growth deceleration (height crosses major percentile lines, growth velocity <25th percentile)
Epidemiology
• ~2.5% of the population by definition

Etiology
• see sidebar

Clinical Presentation
• history and physical exam
  ■ plot on growth curve (special growth charts available for Turner syndrome, achondroplasia, DS)
  ■ assess for dysmorphic features, disproportionate short stature
  ■ risk factors for GH deficiency: previous head trauma, history of intracranial bleed or infection, head surgery or irradiation, positive family history, breech delivery
  ■ decreased growth velocity may be more worrisome than actual height
• investigations
  ■ calculate mid-parental height: children are usually in a percentile between their parents’ height (mid-parental height = (mother + father’s height in cm ± 12.5cm)/2)
  ■ AP x-ray of left hand and wrist for bone age
  ■ GH testing
  ■ remaining investigations guided by history and physical (e.g. TSH, sweat chloride, etc.)

Management
• depends on severity of problem as perceived by parents/child
• no treatment for non-pathological short stature, except for idiopathic short stature
• GH therapy for GH deficiency: if administered at an early age, can help patients achieve adult height requirements
  ■ GH shown to be deficient by 2 different stimulation tests (with argining, glucagon, insulin)
  ■ growth velocity <3rd percentile or height <3rd percentile
  ■ bone age x-rays show unfused epiphyses/delayed bone age
• support and management of resultant self-image issues, social anxiety, etc.

Figure 7. Approach to the child with short stature

TALL STATURE
• height greater than two SD above the mean for a given age, sex, and race

Etiology
• constitutional/familial
  • endocrine: Beckwith-Wiedemann syndrome, hyperthyroidism, hypophyseal gigantism, precocious puberty
  • genetic: homocystinuria, Klinefelter syndrome, Marfan syndrome, Sotos syndrome

Hypercalcemia/Hypocalcemia/Rickets
• see Endocrinology, E37, E39, E42
Hyperthyroidism and Hypothyroidism

- may be congenital or acquired (for acquired causes, see Endocrinology, E22)

CONGENITAL HYPERTHYROIDISM
- also known as neonatal Graves’ disease

**Epidemiology**
- ~1:25,000 neonates, M=F

**Etiology**
- may be classified as permanent or transient congenital hypothyroidism (CH)
  - subcategorize into primary (85% dysgenesis, 15% thyroid gland disorder), secondary/central (pituitary/hypothalamic issue), or peripheral CH (deficits in thyroid hormone transport, metabolism or action)
  - permanent CH requires lifelong treatment, transient CH recovers to normal thyroid after neonatal period
  - causes of transient hypothyroidism: maternal - antibody-mediated, iodine deficiency (rare in developed countries), prenatal exposure to antithyroid medications; neonatal – neonatal iodine deficiency/excess, congenital liver hemangiomas, certain gene mutations

**Clinical Presentation**
- history and physical exam
  - usually asymptomatic in neonatal period because maternal T4 crosses the placenta
  - prolonged jaundice, feeding difficulty, lethargy, constipation, umbilical hernia, macroglossia, large fontanelles, puffy face, swollen eyes
  - examine for congenital malformations (especially cardiac) and dysmorphic features
  - most commonly presents as a positive newborn screen result
- investigations
  - screen all infants for primary CH, repeat screening at 2 wk for infants at high risk: preterm, (very)-low birth weight, infants in NICU, specimen collection <24 h of life, multiple births
  - diagnosis through newborn screening of TSH (most sensitive for primary CH) or free T4; abnormal results should be confirmed with serum levels from venipuncture
    - ↑ TSH, ↓ free T4 in primary CH
    - ↓ TSH, ↑ free T4 in secondary CH
  - primary CH (optional) - radioisotope scanning/ultrasound of thyroid for severity, serum thyroglobulin, maternal antithyroid antibodies, urinary iodine
  - secondary CH: MRI, gene analysis, eye exam for optic nerve hypoplasia (assess pituitary)

**Management**
- thyroxine replacement, hormone normalization should be done within 2 wk to avoid cognitive impairment

**Prognosis**
- excellent outcome if treatment started within 1-2 mo of birth
- if treatment started after 3-6 mo of age, may result in permanent developmental delay and/or disability (mild to profound), intellectual impairment, poor growth, hearing loss

CONGENITAL HYPOTHYROIDISM

**Epidemiology**
- incidence: 1:4,000 1:20,000 newborn births; F:M = 2:1
- one of the most common preventable causes of intellectual disability

**Etiology**
- may be classified as permanent primary, central, or transient hypothyroidism
- ~85% of primary cases are sporadic (mostly thyroid dysgenesis), remaining 15% hereditary (mostly inborn errors of thyroid synthesis)
- causes of transient hypothyroidism: maternal antibody-mediated, iodine deficiency (rare in developed countries), prenatal exposure to antithyroid medications

**Clinical Presentation**
- history and physical exam
  - usually asymptomatic in neonatal period because maternal T4 crosses the placenta
  - prolonged jaundice, constipation, sluggish, hoarse cry, lethargy, poor feeding, macroglossia, coarse facial features, large fontanelles, umbilical hernia
- investigations
  - diagnosis through newborn screening of TSH or free T4; abnormal results should be confirmed with serum levels from venipuncture

**Management**
- thyroxine replacement
Prognosis
• excellent outcome if treatment started within 1-2 mo of birth
• if treatment started after 3-6 mo of age, may result in permanent developmental delay and/or disability (mild to profound)

Sexual Development

AMBIGUOUS GENITALIA

Definition
• newborn or child whose gender is difficult to assign based on the appearance of genitalia
• subtype of DSD: a condition in which development of chromosomal, gonadal, or anatomic sex is atypical
• subtypes: 46,XX DSD, 46,XY DSD, ovotesticular DSD (true hermaphrodite)

Epidemiology
• incidence of genital abnormalities at birth is as high as 1:300
• prevalence of complex anomalies with true sexual ambiguity much lower at ~1:5,000

Etiology
• 46,XY DSD
  ■ inborn error of testosterone biosynthesis or Leydig cell hypoplasia
  ■ 5-α-reductase deficiency, androgen receptor deficiency or insensitivity
  ■ LH/hCG unresponsiveness
• 46,XX DSD
  ■ virilizing CAH (most common)
  ■ maternal source: virilizing ovarian or adrenal tumours, untreated maternal CAH, placental aromatase deficiency
• ovotesticular DSD
  ■ both ovarian follicles and seminiferous tubules in the same patient with a 46 XX karyotype
  ■ mixed gonadal dysgenesis

Risk Factors
• parental consanguinity, positive family history of ambiguous genitalia, early childhood illness/death, or primary amenorrhea, maternal medications during pregnancy (e.g. androgens, progesterones, danazol, phenytoin, aminoglutethimide, endocrine disruptors)

Clinical Presentation
• history
  ■ thorough obstetrical history, including prenatal screens and maternal medications
  ■ family history: autosomal recessive pattern may suggest CAH, X-linked recessive pattern may suggest androgen insensitivity syndrome
• physical exam
  ■ male pseudohermaphrodite (XY): small phallus, hypospadias, undescended testicles
  ■ female pseudohermaphrodite (XX): clitoral hypertrophy, labioscrotal fusion
  ■ look for concurrent midline defects, dysmorphic features, and congenital abnormalities
• investigations
  ■ karyotype and genetic workup as indicated
  ■ blood work: electrolytes and renin (evidence of salt-wasting in CAH); 17-OH-progesterone, androgens, FSH, and LH
  ■ imaging: abdominal U/S to look for uterus, testicles, ovaries

Management
• avoid announcement of probable sex or use of personal pronouns until all tests are complete
• continuous psychosocial support for parents and child during development
• elective surgical reconstruction of genitalia is sometimes possible

CONGENITAL ADRENAL HYPERPLASIA

Definition
• autosomal recessive disorder characterized by the partial or total defect of various synthetic enzymes required for cortisol and aldosterone production in the adrenal cortex
  ■ adrenal cortex normally produces balanced levels of aldosterone, cortisol and androgens

Epidemiology
• occurs in ~1:15,000 live births
• most common cause of ambiguous genitalia in genotypically normal females (46XX)

Etiology
• for biosynthetic pathways of adrenal cortex, see Endocrinology, E29
  ■ 21-OH responsible for ~95% of CAH cases
  ■ results in ↓ cortisol and aldosterone production with shunting toward ↑↑ androgens
  ■ cortisol deficiency leads to elevated ACTH, which causes adrenal hyperplasia
  ■ rarer causes include deficiencies in 11-OH, cholesterol desmolase, 17-OH, and 3-HSD
Clinical Presentation
- depends on which enzyme in cortisol synthesis pathway is defective
- presentation of 21-OH deficiency can be divided into
  - classic deficiency with salt wasting: inadequate aldosterone resulting in FTT, hyperkalemia, hyponatremia, hypoglycemia, acidosis (majority of classic CAH types)
  - classic deficiency without salt wasting: simple virilization with adequate aldosterone levels
    - females typically present with amenorrhea, precocious puberty, polycystic ovaries, hirsutism
    - males typically asymptomatic at birth, may show hyperpigmentation (from overproduction of melanocyte stimulating hormone), penile enlargement, rapid growth and accelerated skeletal maturation; present with signs of virilization later in life
  - non-classic CAH – mild androgen excess, sometimes asymptomatic, virilization present later in life, rarely associated with Addisonian crises
- 21-OH deficiency screening is part of many newborn screening programs across North America
- high serum levels of 17-OH progesterone in random blood sample diagnostic for 21-OH deficiency
  - assess plasma ACTH serum electrolytes, plasma glucose, plasma aldosterone, plasma renin activity, blood gas
  - ultrasound – look for enlarged adrenal gland and presence of uterus

Management
- correct any abnormalities in fluids, electrolytes, or serum glucose
- provide glucocorticoids (e.g. hydrocortisone)/mineralocorticoids (fludrocortisone) as necessary to reduce ACTH levels, extra glucocorticoids in times of stress
- psychosocial support

Prognosis
- complications if untreated include virilization, acne, salt wasting, hypotension

NORMAL PUBERTAL DEVELOPMENT

Physiology
- puberty occurs with the maturation of the HPG axis
  - ↑ pulsatile release of GnRH → ↑ release of LH and FSH → maturation of gonads, release of sex steroids
  - secondary sexual characteristics
  - adrenal production of androgens also required

Females
- onset: age 8-13 yr old (may start as early as 7 yr in girls of African descent)
- usual sequence
  1. thelarche: breast budding
  2. pubarche: axillary hair, body odour, mild acne
  3. growth spurt
  4. menarche: mean age 12.5 yr; indicates that growth spurt is almost complete; menses may be irregular in duration and length of cycle
- early puberty is common and often constitutional, late puberty is rare (rule out organic causes)

Males
- onset: age 9-14 yr old
- usual sequence
  1. testicular enlargement
  2. penile enlargement
  3. pubarche: axillary and facial hair, body odour, mild acne
  4. growth spurt: occurs later in boys
- early puberty is uncommon (rule out organic causes), late puberty is common and often constitutional
- gynecomastia (transient development of breast tissue) is a common self-limited condition seen in 50% of males during puberty (but any discharge from nipple or fixed mass should be investigated)

Tanner Staging
- scale used in pediatrics that defines physical measurements of development based on external primary and secondary sex characteristics
**Precocious Puberty**

**Definition**
- Development of secondary sexual characteristics 2-2.5 SD before population mean
- <8 yr old for females, <9 yr old for males

**Epidemiology**
- 1/10,000; F>M

**Etiology**
- Usually idiopathic in females (90%), more suggestive of pathology in males (50%)
- Central (GnRH dependent)
  - Hypergonadotropic hypergonadism; hormone levels as in normal puberty
  - Premature activation of the HPG axis
  - Differential diagnosis: idiopathic or constitutional (most common in females), CNS disturbances
    (tumours, hamartomas, post-meningitis, increased ICP, radiotherapy), NF, primary severe hypothyroidism
- Peripheral (GnRH independent)
  - Hypogonadotropic hypergonadism
  - Differential diagnosis: adrenal disorders (CAH, adrenal neoplasm), testicular/ovarian tumour,
    gonadotropin/hCG secreting tumour (hepatoblastoma, intracranial teratoma, germinoma),
    exogenous steroid administration, McCune-Albright syndrome, aromatase excess syndrome, rarely
    hypothyroidism (Van Wyk-Grumbach syndrome), primary severe hypothyroidism

**Clinical Presentation**
- History
  - Symptoms of puberty, family history of precocious puberty, medical illness
- Physical exam
  - Growth velocity
    - Prepubertal: 4 to 6 cm/yr
    - Growth spurt: boys 8-10 cm/yr, girls 6-8 cm/yr
  - Complete physical exam, including Tanner staging and neurological assessment
- Investigations
  - Initial screening tests: bone age, serum hormone levels (estradiol, testosterone, LH, FSH, TSH, free
    T4, DHEA-S, 17-OH-progesterone)
  - Secondary tests: MRI head, pelvic U/S, β-hCG, GnRH, and/or ACTH stimulation test

**Management**
- Indications for medical intervention to delay progression of puberty: rapid advancement of puberty,
  early age, risk of compromise of final adult height, psychological
- Central causes: goals are to preserve height and alleviate psychosocial stress; GnRH agonists
  (e.g. leuprolide) most effective
- Peripheral causes: goal is to limit effects of elevated sex steroids; treat underlying cause; medications that
  decrease the production of a specific sex steroid or block its effects (e.g. ketoconazole, spironolactone,
  tamoxifen, anastrozole), surgical intervention

---

---

*A child with proven central precocious puberty should receive an MRI of the brain.*
DELAYED PUBERTY

Definition
- failure to develop secondary sex characteristics by 2-2.5 SD beyond the population mean
  - for males: lack of testicular enlargement by 14 yr old
  - for females: lack of breast development by 13 yr old OR absence of menarche by 16 yr old or within 5 yr of pubertal onset

Epidemiology
- M>F

Etiology
- usually constitutional delay in males, more suggestive of pathology in females
  - central causes
    - constitutional delay in activation of HPG axis (most common)
    - hypogonadotropic hypogonadism
  - peripheral causes
    - hypergonadotropic hypogonadism (e.g. primary gonadal failure, gonadal damage, Turner syndrome, hormone deficiency, androgen insensitivity syndrome, etc.)

Clinical Presentation
- history: weight loss, short stature, family history of puberty onset, medical illness, high performance athletes (females)
  - physical exam: growth velocity (minimum 4 cm/yr), Tanner staging, neurological exam, complete physical exam
  - investigations
    - initial screening tests: bone age, serum hormone levels (estradiol, testosterone, LH, FSH, TSH, free T4, T3, ACTH, PRL), CBC, electrolytes, BUN, Cr, LFTs, liver enzymes, ESR, CRP, urinalysis
    - secondary tests: MRI head, pelvic U/S, karyotype, IBD panel, celiac disease panel, LH levels following GnRH agonist

Management
- identify and treat underlying cause
- hormonal replacement: cyclic estradiol and progesterone for females, testosterone for males

Gastroenterology

Vomiting

History
- characteristic of emesis (e.g. projectile, bilious, bloody)
- pattern of emesis (e.g. association with feeds, cyclic, morning)
- associated symptoms (e.g. anorexia, diarrhea, etc.)
- red flags: bilious or bloody emesis, projectile vomit, abdominal distension and tenderness, high fever, signs of dehydration
- note that vomiting without diarrhea is most likely not gastroenteritis.
  - post tussive vomiting is also common with coughing fits in children

Physical Findings
- vital signs to determine clinical status and hydration state

Investigations
- CBC, electrolytes, BUN, Cr, amylase, lipase, glucose done routinely
- in sick child, add: ESR, venous blood gases, C&S (blood, stool), imaging

</tr>
</tbody>
</table>

Management
- rehydration (see Fluids and Electrolytes, P69)
- treat underlying cause
  - antiemetic drugs can be used in children >2 years with severe vomiting is severe: promethazine, prochlorperazine, metoclopramide, ondansetron

**Gastroesophageal Reflux**

**Epidemiology**
- extremely common in infancy (up to 50%) but rarely causes GERD (GER disease)

**Clinical Presentation**
- vomiting typically soon after feeding, non-bilious, rarely contains blood, small volume (<30 mL)
  - when to suspect gastroesophageal reflux disease (GERD), defined as when GER causes troublesome symptoms/complications
    - infant: poor weight gain, irritability, sleep disturbance, respiratory symptoms (coughing, choking, wheezing)
    - older child/adolescent: abdominal pain/heart burn, dysphagia, asthma, recurrent pneumonia/upper respiratory infections, recurrent otitis media, upper airway symptoms (chronic cough, hoarseness), dental erosions

**Investigations**
- thriving baby requires no investigation
- GERD can be a clinical diagnosis but diagnostic investigations may include
  - upper GI tract radiography – assesses anatomy and motility disorder
  - esophageal pH – quantify GER
  - upper endoscopy and esophageal biopsy – rule out other conditions that mimic GERD symptoms, assess GERD-related esophageal injury
  - warning signs of associated disorders requiring further investigations: bilious vomiting, GI tract bleeding, consistently forceful vomiting, fever, lethargy, hepatosplenomegaly, buging fontanelle, micro/macrocephaly, seizures, abdominal tenderness/distension, suspected genetic, metabolic syndrome or chronic disease

**Management**
- conservative (infant): thickened feeds, frequent and smaller feeds, elevation of head, changing formula to hydroyzled protein or amino acid based formula
- breastfeeding infants – mothers exclude milk and egg in diet
- older children/adolescent – same as adult management (see Gastroenterology, G6)
- medical
  - short-term parenteral feeding to enhance weight gain
  - ranitidine, PPI: decreases gastric acidity, decreases esophageal irritation
  - domperidone, metoclopramide: improves gastric emptying and GI motility; safety concerns and limited efficacy, should be reserved for children with gastroparesis contributing to GERD
- surgical: indicated for failure of medical therapy (Nissen fundopl cation)

**Complications**
- esophagitis, strictures, Barrett's esophagus, FTT, aspiration, oral feeding aversion
Tracheoesophageal Fistula
• see General Surgery, GS64

Pyloric Stenosis
• see General Surgery, GS62

Duodenal Atresia
• see General Surgery, GS63

Malrotation of the Intestine
• see General Surgery, GS63

Diarrhea
• definition of diarrhea varies with diet and age (stool normalcy difficult to define in children)
  infants → increase in stool frequency to twice as often per day; older children → 3+ loose or watery
  stools/d
  • duration: acute; <2 wk; chronic: >2 wk

Pathophysiology
• osmotic: due to non-absorbable solutes in GI tract (e.g. lactose intolerance)
• secretory: increased secretion of Cl– ions and water in intestinal lumen (e.g. bacterial toxin)
• malabsorption: less time for absorption due to increased motility or less villi to absorb (e.g. short bowel
  syndrome)

History
• frequency, duration, quality of diarrhea
• associated symptoms (e.g. fever, abdominal pain, hematochezia, etc.)
• recent antibiotic use or recent travel
• elements of diet

Physical Findings
• vital signs to determine clinical status and hydration state

Investigations
• acute diarrhea
  • stool for C&S, O&P, electron microscopy for viruses, C. difficile toxin, microscopy (leukocytes
    suggestive of invading pathogen), blood and urine cultures, blood work
  • chronic diarrhea
  • serial heights, weights, growth percentiles
  • if child growing well and thriving, workup is limited (stool cultures as above, stool reducing substances)
  • red flags: poor growth, chronic rash, other serious infections, hospitalizations for dehydration
  • require full workup (as per below)
  • stool: consistency, pH, reducing substances, microscopy, occult blood, O&P, C&S, C. difficile toxin,
    3 d fecal fat, α-1-antitrypsin clearance, fecal elastase
  • urinalysis, urine culture
  • CBC, differential, ESR/CRP, smear, electrolytes, total protein, albumin, carotene, Ca2+, PO43–, Mg2+, Fe,
    ferritin, folate, fat-soluble vitamins, PT, INR
  • sweat chloride, celiac screen, thyroid function tests, urine VMA and HVA, HIV test, lead levels
  • CXR, upper GI series and follow-through
  • specialized tests: endoscopy, small bowel biopsy

Diarrhea is defined as an increase in
frequency and/or decreased consistency of
stools compared to normal

Normal stool volume
Infants: 5-10 g/kg/d
Children: 200 g/d

Diarrhea Red Flags
Bloody stool, fever, petechiae or purpura,
signs of severe dehydration, weight loss/FTT

Common Antibiotics that Can Lead to C.
difficle Infection
• Fluoroquinolones
• Clindamycin
• Penicillins (broad spectrum)
• Cephalosporins (broad spectrum)

Gastroenteritis

**History**
- non-specific: diarrhea, vomiting, fever, anorexia, headache, myalgias, abdominal cramps
- bacterial and parasitic agents more common in older children (2-4 yr)
- recent infectious contacts: symptoms usually begin 24-48 h after exposure

**Physical Exam**
- febrile
- dehydrated: must assess extent (see Approach to Infant/Child with Dehydration, P69)

**Investigations**
- not usually necessary in young children
- stool analysis: leukocytes/erythrocytes suggests bacterial or parasitic etiology; pH <6 and presence of reducing substances suggests viral etiology

**Complications**
- viral gastroenteritis usually self-limiting (lasts 3-7 d in most cases)
- adverse effects related to hypovolemia, shock, tissue acidosis, and rapid onset and over-correction of electrolyte imbalances
- death in severe dehydration (rare in developed countries)

</tbody>
</table>
Toddler’s Diarrhea

Epidemiology
• most common cause of chronic diarrhea during infancy
• onset between 6-36 mo of age, ceases spontaneously between 2-4 yr

Clinical Presentation
• diagnosis of exclusion in thriving child
• 4-6 bowel movements per day
• diet history (e.g. excess juice intake overwhelms small bowel resulting in disaccharide malabsorption)
• stool may contain undigested food particles
• excoriated diaper rash

Management
• reassurance that it is self-limiting
• 4Fs (adequate Fibre, normal Fluid intake, 35-40% Fat, discourage excess Fruit juice)

Lactase Deficiency (Lactose Intolerance)

Clinical Presentation
• chronic, watery diarrhea and abdominal pain, bloating associated with dairy intake
• primary lactose intolerance: crampy abdominal pain with loose stool (older children, usually of East Asian and African descent)
• secondary lactose intolerance: older infant, persistent diarrhea (decreased lactase production post viral/bacterial infection, celiac disease, or IBD)

Diagnosis
• trial of lactose-free diet
• watery stool, acid pH, positive reducing sugars
• positive breath hydrogen test if >6 yr

Management
• lactose-free diet, soy formula
• lactase-containing tablets/capsules/drops (e.g. Lacteeze®, Lactaid®)

Irritable Bowel Syndrome

• see Gastroenterology, G23

Celiac Disease

• see Gastroenterology, G18
• in children: presents at any age, usually 6-24 mo with the introduction of gluten in the diet
• FTT with poor appetite, irritability, apathy, rickets, wasted muscles, flat buttocks rarely distended abdomen
• GI symptoms: anorexia, N/V, edema, anemia, abdominal pain
• non-GI manifestations: iron-deficiency anemia, dermatitis herpetiformis, dental enamel hypoplasia, osteopenia/osteoporosis, short stature, delayed puberty, behavioural changes
• associated with other autoimmune disorders (e.g. Type 1 diabetes MS, autoimmune hepatitis)

Milk Allergy (MA) & Cow’s Milk Protein Allergy

Pathophysiology
milk allergy (MA) is IgE mediated whereas cow’s milk protein allergy (i.e. food protein induced proctocolitis of infancy (FPIPI) is non-IgE mediated and more common

Clinical Presentation
• MA reactions occur within hours of exposure and are present on the skin (urticular, pruritus), upper and lower resp tract symptoms (wheeze, cough)
• FPIPI occurs between 2-8 of infancy, presents with:
  • proctocolitis: mild diarrhea, small amounts of bloody stools (common presentation in young infant)
  • enterocolitis: vomiting, diarrhea, anemia, hematochezia, constipation
  • enteropathy: chronic diarrhea, hypoalbuminemia
• up to 50% of children intolerant to cow’s milk may be intolerant to soy protein as well

Investigation
• food challenge (gold standard), skin prick test, serum measurement of allergen-specific IgE, patch testing
Management
• MA: stop exposure
• FPIPI: stop, reintroduce milk at 6-8 mo, vast majority (>90%) will outgrow intolerance by 1 yr
• casein hydrolysate formula (dairy-free e.g. Nutramigen®, Pregestimil®) or mother may sequentially remove cow's milk protein, all bovine protein, soy protein, legumes (7 d washout) and continue breastfeeding (with adequate calcium and vit D intake)

Inflammatory Bowel Disease
• see Gastroenterology, G19

Cystic Fibrosis
• see Respirology, P84

Constipation
• decreased stool frequency (<3 stools/wk) and/or stool fluidity (hard, pellet-like)

FUNCTIONAL CONSTIPATION
• 99% of cases of constipation
• Rome III criteria; ≥2 of the following
  ■ ≤2 defecations in the toilet/wk
  ■ ≥1 episode of fecal incontinence/wk
  ■ history of retentive posturing or excessive volitional stool retention
  ■ history of painful or hard bowel movements
  ■ large fecal mass in rectum
  ■ history of large diameter stools that may obstruct toilet

Pathophysiology
• lack of fibre in diet or change in diet, poor fluid intake, behavioural
  ■ infants: often occurs when introducing cow's milk after breast milk due to high fat and solute content, lower water content
  ■ toddlers/older children: can occur during toilet training or due to pain on defecation, leading to withholding of stool
  ■ two crucial time periods: toilet training and starting school

Management
• education: explanation of mechanism of functional constipation for parents/older children
• clean out: PEG 3350 flakes (1-1.5 g/kg/d, max 100 g/d), picosalax, PEGlyte®
• maintenance: adequate fluid intake (if <6 mo, 150 mL/kg/d), adequate dietary fibre (fruit, vegetables, whole grains), stool softening (PEG 3350, mineral oil), appropriate toilet training technique (dedicated time for defecation: 3-10 min, 1-2 x/d)
• children should be treated for at least 6 mo, and should not be weaned from maintenance therapy until they are having regular bowel movements without difficulty
• regular follow-up with ongoing support and encouragement is essential

Complications
• pain retention cycle: anal fissures + pain from withholding passing stool, chronic dilatation ± overflow incontinence

HIRSCHSPRUNG’S DISEASE (Congenital Aganglionic Megacolon)
• see General Surgery, GS64

OTHER ORGANIC DISORDERS CAUSING CONSTIPATION
• endocrine: hypothyroidism, DM, hypercalcemia
• neurologic: spinal cord abnormalities/trauma, NF
• anatomic: bowel obstruction, anus (imperforate, atresia, stenosis, anteriorly displaced)
• drugs: lead, chemotherapy, opioids
• others
Abdominal Pain

ACUTE ABDOMINAL PAIN

History
description of pain (location, radiation, duration, constant vs. colicky, relation to meals)
- associated symptoms: N/V, diarrhea, fever

Physical Exam
- abdominal exam, rectal exam, rash

Investigations
- CBC, differential, urinalysis to rule out UTI

Table 16. Differential Diagnosis of Acute Abdominal Pain

</table>

APPENDICITIS
- see General Surgery, GS27
- most common cause of acute abdomen after 5 yr of age
- clinical features: low grade fever, abdominal pain, anorexia, N/V (after onset of pain), peritoneal signs (generalized peritonitis is a common presentation in infants/young children)
- treatment: surgical
- complications: perforation (common in young children), abscess

INTUSSUSCESSION
- telescoping of segment of bowel into distal segment causing ischemia and necrosis

Epidemiology
- 90% idiopathic, children with CF or GJ tube at significantly increased risk; M:F = 3:1
- 50% between 3-12 mo, 75% before 2 yr of age

Pathophysiology
- usual site: ileocecal junction; jejunum in children with GJ tubes
- lead point of telescoping segment may be swollen Peyer’s patches, Meckel’s diverticulum, polyp, malignancy, HSF structural abnormalities

Clinical Presentation
- “classic triad” (<25% patients) - abdominal pain, palpable mass, red currant jelly stools
  - often preceded by URTI
- sudden onset of recurrent, paroxysmal, severe periumbilical pain with pain-free intervals
- later vomiting (may be bilious) and rectal bleeding (late finding)
- shock and dehydration; lethargy may be only presenting symptom

Diagnosis
- U/S, air enema

Management
- air enema can be therapeutic (reduces intussusception in 75% of cases), reduction under hydrostatic pressure, surgery rarely needed
- recurrence rate 10-15%, need to consider pathologic lead point
**Chronic Abdominal Pain**

**Epidemiology**
- prevalence: 10% of school children (peak at 8-10 yr), F>M

**Etiology**
- organic (<10%)
  - gastrointestinal
  - constipation (cause vs. effect), infectious
  - IBD, esophagitis, peptic ulcer disease, lactose intolerance
  - anatomic anomalies, masses
  - pancreatic, hepatobiliary
  - celiac disease
  - genitourinary causes: recurrent UTI, nephrolithiasis, chronic PID, Mittelschmerz
  - neoplastic
- functional abdominal pain (90%): can be diagnosed when there are no alarming signs or symptoms, physical exam is normal, and stool sample tests are negative for occult blood; no further testing is required, unless high suspicion for organic cause
  - alarming symptoms include involuntary weight loss, deceleration of linear growth, GI blood loss, significant vomiting, chronic severe diarrhea, persistent upper or right lower quadrant pain, unexplained fever, family history of IBD
  - can be further subclassified into functional dyspepsia (pain in upper abdomen), irritable bowel syndrome (alternating bowel movements), abdominal migraine (paroxysmal abdominal pain, associated with anorexia, nausea, vomiting, pallor), functional abdominal pain syndrome

**Clinical Presentation**
- clustering episodes of vague, crampy periumbilical/epigastric pain, vivid pain description
- seldom awakens child from sleep, less common on weekends
- aggravated by exercise, alleviated by rest
- psychological factors related to onset and/or maintenance of pain, school avoidance
- psychiatric comorbidity: anxiety, somatoform, mood, learning disorders, sexual abuse, eating disorders, elimination disorders
- diagnosis of exclusion

**Investigations**
- fecal occult blood and others based on clinical suspicion (CBC, ESR, urinalysis, etc.)

**Management**
- continue to attend school
- manage any emotional or family problems, counselling, CBT
- trial of high fibre diet, trial of lactose-free diet
  - medication should be for symptom relief – acid reduction therapy for dyspepsia, antispasmodic agents, smooth muscle relaxants for pain, nonstimulating laxatives or antidiarrheals for altered bowel pattern
- possible role for amitriptyline
- reassurance

**Prognosis**
- pain resolves in 30-50% of children within 2-6 wk of diagnosis
- 30-50% of children with functional abdominal pain have functional pain as adults (e.g. IBS)

**Abdominal Mass**

**Upper Gastrointestinal Bleeding**
- see Gastroenterology, G25
Lower Gastrointestinal Bleeding

- see Gastroenterology, G27

Etiology
- acute
  - infectious (bacterial, parasitic)
  - antibiotic-induced (C. difficile)
  - NEC in preterm infants
  - anatomic
  - malrotation/volvulus, intussusception
  - Meckel's diverticulitis
  - anal fissures, hemorrhoids
  - vascular/hematologic
  - HSP
  - HUS
  - coagulopathy

- chronic
  - anal fissures (most common)
  - colitis
  - IBD
  - allergic (milk protein)
  - structural
  - polyps (most are hamartomas)
  - neoplasms (rare)
  - coagulopathy

Physical Exam
- hemodynamic status, evidence of FTT, fever
- anal and rectal exam: tags, fissures, anal fistulas, polyps, foreign body, blood per rectum
- stool appearance
- NG aspirate
- lower GI bleed may present as melena (if it involves the small bowel) or hematochezia

Investigations
- stool cultures (C&S, C. difficile toxin)
- urinalysis and microscopy
- CBC, smear, differential, ESR, CRP, electrolytes, urea, Cr, INR, PTT, albumin iron studies, amoeba titers
- radiologic investigations (including abdominal x-ray to rule out obstruction)
- Meckel's radionuclide scan

Management
- acute stabilization: ABCs, volume and blood replacement, bowel rest (NPO, NG tube)
- once stable, endoscopy and/or surgery as indicated

Genetics, Dysmorphisms, and Metabolism

- see Medical Genetics

Hematology

Approach to Anemia

![Figure 9. Approach to anemia](image-url)
Physiologic Anemia

- high Hb (>170 g/L) and reticulocyte count at birth is caused by a hypoxic environment in utero
- after birth, levels start to fall due to shorter fetal RBC lifespan, decreased RBC production (during first 6-8 wk of life, there is virtually no erythropoiesis due to new O2-rich environment), and increasing blood volume secondary to growth
- lowest levels about 100 g/L at 8-12 wk age (earlier and more exaggerated in premature infants); levels rise spontaneously with activation of erythropoiesis
- usually no treatment required

Iron Deficiency Anemia

- most common cause of childhood anemia
- full term infants exhaust iron reserves by 6 mo of age
- premature infants have lower reserves, therefore exhausted by 2-3 mo of age
- common diagnosis between 6 mo-3 yr and 11-17 yr due to periods of rapid growth and increased iron requirements; adolescents also have poor diet and menstrual losses

Etiology
- children at risk (premature, LBW, low SES, etc.)
- dietary risk factors: whole cow milk in first year of life
- age > 6 mo: <2 servings/d of iron-fortified cereal, red meat, or legumes
- age < 12 mo: use of low-iron formula (<10 mg/L), primary diet of cow, goat, or soy milk
- age 1-5 yr: >16-20 oz/d of non-fortified milk
- blood loss
  - iatrogenic: repeated blood sampling (especially in hospitalized neonates)
  - allergic: cow’s milk protein-induced colitis

Clinical Manifestation
- usually asymptomatic until marked anemia. Symptoms may include: pallor, fatigue, pica (eating non-food materials), tachycardia, systolic murmur, angular cheilitis, koilonychia (spoon nails)

Investigations
- CBC: low Hb, MCV, and MCH, reticulocyte count normal or high (absolute number low)
- Mentzer index (MCV/RBC) can help distinguish iron deficiency anemia from thalassemia
  - ratio < 13 suggests thalassemia
  - ratio > 13 suggests iron deficiency
- blood smear: hypochromic, microcytic RBCs, pencil shaped cells, poikilocytosis
- iron studies: low ferritin, other (low iron, high total iron binding capacity, high transferrin, low transferrin saturation)
- initial therapy: trial of iron

Prevention
- breastfed term infants: begin iron supplementation (1 mg/kg/d) at 4-6 mo, continuing until able to eat ≥2 feeds/d of iron-rich foods
- non-breastfed (<50% of diet) term infants: give iron-fortified formula from birth
- premature infants: give iron supplements from 1 mo through to 1 yr of age
- no cow’s milk until 9-12 mo, early introduction of red meat and iron-rich vegetables: total daily iron should be 11 mg (age 6-12 mo), 7 mg (age 1-3 yr)
- universal screening of Hb levels recommended at 9 mo

Management
- encourage diverse, balanced diet, limit homogenized milk to 16-20 oz/d
- oral iron therapy: 4-6 mg/kg/d elemental iron, divided bid to tid, for 3 mo
  - increased reticulocyte count in 2-3 d (peaks day 5-7)
  - increased hemoglobin in 4-30 d
  - repletion of iron stores in 1-3 mo
  - repeat hemoglobin levels after 1 mo of treatment
- poor response to oral iron therapy: non-adherence, medication intolerance, ongoing blood loss, IBD, celiac disease, incorrect diagnosis

Complications
- can cause irreversible effects on development if untreated (behavioural and intellectual deficiencies)
- angular cheilitis, glossitis, koilonychia (spoon nails)
**Vitamin K Deficiency**

**Etiology**
- Hemorrhagic disease of the newborn due to relative deficiencies of vitamin K-dependent coagulation factors
  - Generalized bleeding: GI/intracranial hemorrhage
  - IM injection at birth, can also be given orally (3 doses: at birth, 2-4 wk, 6-8 wk) but infants at higher risk of HDNB
  - Reason for administration at birth:
    - Human milk contains small amounts of vitamin K, and infants require ingestion of large volumes of human milk to promote GI bacterial colonization
    - Until few days after birth, susceptible to vitamin K deficiency

**Anemia of Chronic Disease**

DIC = disseminated intravascular coagulation; PFA = platelet function assay; VIII:C = Factor VIII coagulant activity; vWF = von Willebrand Factor

**Immune Thrombocytopenic Purpura**

**Epidemiology**
- Most common cause of thrombocytopenia in childhood
- Peak age: 2-6 yr, M=F
- Incidence 5:100,000 children per year

**Etiology**
- Caused by autoantibodies that bind to platelet membranes → Fc-receptor mediated splenic uptake → destruction of platelets
Clinical Presentation
- 50% present 1-3 wk after viral illness (e.g. URTI, chicken pox)
- sudden onset of petechiae, purpura, epistaxis in an otherwise well child
- clinically significant bleed in only 3% (severe bleed more likely with platelet count <10) with <0.5% risk of intracranial bleed
- no lymphadenopathy, no hepatosplenomegaly
- labs: thrombocytopenia with normal RBC, WBC
- bone marrow aspirate only if atypical presentation (≥1 cell line abnormal, hepatosplenomegaly)
- differential diagnosis: leukemia, drug-induced thrombocytopenia, HIV, infection (viral), autoimmune (SLE, ALPS)

Management
- observation vs. pharmacologic intervention highly debated; spontaneous recovery in >70% of cases within 3 mo
- treatment with IVIg or prednisone if mucosal or internal bleeding, platelets <10, or at risk of significant bleeding (surgery, dental procedure, concomitant vasculitis or coagulopathy)
- life-threatening bleed: additional platelet transfusion ± emergency splenectomy
- persistent (>3-12 mo) or chronic (>12 mo): re-evaluate; treat if symptoms persist
- supportive: avoid contact sports and ASA/NSAIDs

Hemophilia
- see Hematology, H31

von Willebrand’s Disease
- see Hematology, H30

Oncology
- cancer is the second most common cause of death after injuries in children >1 yr of age
- cause is rarely known, but increased risk for children with: chromosomal syndromes (e.g. Trisomy 21), cancer predisposition syndromes (e.g. Li-Fraumeni syndrome), prior malignancies, neurocutaneous syndromes, immunodeficiency syndromes, family history, exposure to radiation, chemicals, biologic agents
- leukemias are the most common type of pediatric malignancy (30%) followed by brain tumours (25%), and lymphomas (15%)
- some malignancies are more prevalent in certain age groups
  - newborns: neuroblastoma, Wilms’ tumour, retinoblastoma
  - infancy and childhood: leukemia, neuroblastoma, CNS tumours, Wilms’ tumour, retinoblastoma
  - adolescence: lymphoma, gonadal tumours, germ cell tumours, bone tumours
- unique treatment considerations in pediatrics because radiation, chemotherapy, and surgery can impact growth and development, endocrine function, and fertility
- good prognosis: treatments have led to remarkable improvements in overall survival and cure rates for many pediatric cancers (>80%)

Lymphadenopathy

Clinical Presentations
- features of malignant lymphadenopathy: firm, discrete, non tender, enlarging, immobile ± suspicious mass/imaging findings ± constitutional symptoms
- fluctuance, warmth, or tenderness are more suggestive of benign nodes (infection)

Differential Diagnosis
- infection
  - viral: URTI, EBV, CMV, adenovirus, HIV
  - bacterial: S. aureus, GAS, anaerobes, Mycobacterium (e.g. TB), cat scratch disease (Bartonella)
  - other: fungal, protozoan, Rickettsia
- autoimmune: rheumatoid arthritis, SLE, serum sickness
- malignancy: lymphoma, leukemia, metastatic solid tumours
- storage diseases: Niemann-Pick, Gaucher’s
- other: sarcoidosis, Kawasaki disease, histiocytoses

The American Society of Hematology 2011 Evidence-Based Practice Guideline for Immune Thrombocytopenia
Blood 2011;117(16):4190-207
Recommendations
- Bone marrow examination is unnecessary in children and adolescents with the typical features of ITP.
- Bone marrow examination is not necessary in children who fail IVIg therapy (grade 1B).
- Children with no bleeding or mild bleeding (defined as skin manifestations only, such as bruising and petechiae) may be managed without observation alone regardless of platelet count.
- For pediatric patients requiring treatment, a single dose of IV (0.8-1 g/kg) or a short course of corticosteroids may be useful as first-line treatment.
- IVIg can be used if a more rapid increase in the platelet count is desired.
- Anti-D therapy is not advised in children with a hematoglobin concentration that is decreased due to bleeding, or with evidence of autoimmune hemolytic anemia.

Suggestions
- Bone marrow examination is also not necessary in similar patients prior to initiation of treatment with corticosteroids or before splenectomy.
- Testing for antinuclear antibodies is not necessary in the evaluation of children and adolescents with suspected ITP.
- A single dose of anti-D can be used as first-line treatment in Rh-positive, nonsplenectomized children requiring treatment.
Investigations

- generalized lymphadenopathy
  - CBC and differential, blood culture
  - uric acid, LDH
  - ANA, RF, ESR
  - EBV/CMV/HIV serology
  - toxoplasma titre
  - fungal serology
  - CXR
  - TB tests
  - biopsy

- regional lymphadenopathy
  - period of observation if asymptomatic
  - trial of oral antibiotics
  - ultrasound
  - biopsy (especially if persistent >6 wk and/or constitutional symptoms)

Leukemia

- see Hematology, H37

Epidemiology

- mean age of diagnosis 2-5 yr but can occur at any age
- heterogeneous group of diseases
  - ALL (80%)
  - AML (15%)
  - CML (<5%)
- children with DS are 15x more likely to develop leukemia

Clinical Presentation

- infiltration of leukemic cells into bone marrow results in bone pain and bone marrow failure (anemia, neutropenia, thrombocytopenia)
- infiltration into tissues results in lymphadenopathy, hepatosplenomegaly, CNS manifestations, testicular disease
- fever, fatigue, weight loss, bruising, and easy bleeding
- hyperleukocytosis (total WBC >100 x 10⁹/L) is a medical emergency
  - presents clinically with respiratory or neurological distress caused by hyperviscosity of blood and leukostasis
  - risk of ICH, pulmonary leukostasis syndrome, tumour lysis syndrome
- management: fluids, allopurinol/rasburicase, fresh frozen plasma/platelets to correct thrombocytopenia, induction chemotherapy, avoid transfusing RBCs unless symptomatic (and then use very small volumes)

Management

- fluids, allopurinol/rasburicase, fresh frozen plasma/platelets to correct thrombocytopenia, induction chemotherapy, avoid transfusing RBCs unless symptomatic (and then use very small volumes)
- combination chemotherapy using non-cross resistant chemotherapy agents, allogeneic stem cell transplantation for high-grade or recurrent disease
- supportive care and management of treatment complications
  - febrile neutropenia: see Infectious Diseases, ID45
  - tumour lysis syndrome: see Hematology, H52

Prognosis

- 80-90% 5 yr event-free survival for ALL, 50-60% 5-yr survival for AML
- patients are stratified into standard risk and high risk based on WBC and age; other prognostic factors include presence of CNS/testicular disease, immunophenotype, cytogenetics, and initial response to therapy (most important prognostic variable)

Lymphoma

- see Hematology, H45

Epidemiology

- Hodgkin lymphoma: incidence is bimodal, peaks at ages 15-34 and >50 yr old
- non-Hodgkin lymphoma: incidence peaks at 7-11 yr

Clinical Presentation

- Hodgkin lymphoma
  - most common presentation is persistent, painless, firm, cervical or supraclavicular lymphadenopathy
  - can present as persistent cough or dyspnea (secondary to mediastinal mass) or less commonly as splenomegaly, axillary, or inguinal lymphadenopathy
  - constitutional symptoms in 30% of children
  - lymph nodes become sequentially involved as disease spreads

- Back pain in children must always be investigated!
  - Unlike adults, back pain in children often points to a pathological process
• non-Hodgkin lymphoma
  ■ generally categorized into lymphoblastic, large cell, and Burkitt's/Burkitt's-like lymphoma
  ■ rapidly growing tumour with distant metastases (unlike adult non-Hodgkin lymphoma)
  ■ signs and symptoms related to disease site: most commonly abdomen, chest (mediastinal mass), head and neck region

Management
• Hodgkin lymphoma
  ■ combination chemotherapy and radiation
  ■ aimed at limiting cumulative doses of anthracyclines (toxic to heart) and alkylators (risk of second malignancy, infertility) and limiting dose and field of radiation
  ■ increasing role for use of PET scanning to assess early disease response and plan therapy
• non-Hodgkin lymphoma
  ■ combination chemotherapy
  ■ no added benefit of radiation in pediatric protocols

Prognosis
• Hodgkin lymphoma: >90% 5 yr survival
• non-Hodgkin lymphoma: 75-90% 5 yr survival

Brain Tumours
• see Neurosurgery, NS11

Wilms’ Tumour (Nephroblastoma)

Epidemiology
• usually diagnosed between 2-5 yr; M=F
  ■ most common primary renal neoplasm of childhood
  ■ 5-10% of cases both kidneys are affected (simultaneously or in sequence)

Differential Diagnosis
• hydronephrosis, polycystic kidney disease, renal cell carcinoma, neuroblastoma

Clinical Presentation
• 80% present with asymptomatic, unilateral abdominal mass
• may also present with HTN, gross hematuria, abdominal pain, vomiting
• may have pulmonary metastases at time of diagnosis (respiratory symptoms)

Associated Congenital Abnormalities
• WAGR syndrome (Wilms’ tumour, Aniridia, Genital anomalies, mental Retardation) with 11p13 deletion
• Beckwith-Wiedemann syndrome:
  ■ characterized by enlargement of body organs (especially tongue), hemihypertrophy, renal medullary cysts, and adrenal cytomegaly
  ■ also at increased risk for developing hepatoblastoma, and less commonly adrenocortical tumours, nephroblastomas, and rhabdomyosarcomas
• Denys-Drash syndrome characterized by gonadal dysgenesis and nephropathy leading to renal failure

Management
• staging ± nephrectomy
• chemotherapy, radiation for higher stages

Prognosis
• 90% long-term survival

Neuroblastoma

Epidemiology
• most common cancer occurring in first year of life
• neural crest cell tumour arising from sympathetic tissues (neuroblasts)

Clinical Presentation
• can originate from any site in sympathetic nervous system, presenting as mass in neck, chest, or abdomen (most common site is adrenal gland)
• signs and symptoms of disease vary with location of tumour
  ■ thoracic: dyspnea, Horner's syndrome
  ■ abdomen: palpable mass
  ■ spinal cord compression
metastases are common at presentation (>50% present with advanced stage disease):
- usually to bone or bone marrow (presents as bone pain, limp)
- can also present with peri-orbital ecchymoses, abdominal pain, emesis, fever, weight loss, anorexia, hepatomegaly, "blueberry muffin" skin nodules
- paraneoplastic: HTN, palpitations, sweating (from excessive catecholamines), diarrhea, FTT (from vasoactive intestinal peptide secretion), opsomyoclonus

Management
- depends on prognostic factors and may include combination of: surgery, radiation, chemotherapy, autologous stem cell transplantation, immunotherapy

Prognosis
- prognosis is often poor due to late detection
- good prognostic factors
  - "age and stage" are important determinants of better outcome: <18 mo, stage I, II, IV-S disease ("S" designates a "Special" classification only pertaining to infants)
  - primary site: posterior mediastinum and neck
  - low serum ferritin
  - more differentiated histology
  - tumour cell markers: aneuploidy, absent MYCN oncogene amplification

Bone Tumours

Cancer Predisposition Syndromes
- suspected in cases of multiple primary neoplasms, especially early onset for cancer type and/or family history consistent with known cancer predisposition syndrome (critical to obtain family history and refer if syndrome suspected)
- cancer predisposition syndromes with pediatric onset include Li-Fraumeni syndrome (soft tissue sarcomas, osteosarcoma, CNS tumours and adrenal cortical carcinoma), hereditary retinoblastoma and Fanconi anemia (leukemias)

Infectious Diseases

Fever

Definition
- fever: a practical definition is >38°C/100.4°F oral or rectal
- fever without a source/focus: acute febrile illness (typically <10 d duration) with no cause of fever even after careful history and physical
- fever of unknown orIGIN: daily or intermittent fevers for at least 2 consecutive wk of uncertain cause after careful history and physical, and initial laboratory assessment

Etiology
- infectious: anatomic approach (CNS, ears, upper and lower respiratory tract, GI, GU, skin, soft tissue, bones and joints, etc.)
- inflammatory: mainly autoimmune (Kawasaki disease, JIA, IBD, SLE, etc.)
- malignancy: childhood cancers (leukemia, lymphoma, neuroblastoma, etc.)
- miscellaneous: dehydration, drugs and toxins, post-immunization, familial dysautonomia, factitious disorder, etc.

Diagnosis
- history: duration, height and pattern of fever, associated symptoms, exposures, constitutional symptoms, recent antipyretic use, ethnic or genetic background, day care, sick contacts, travel, tick bites, age of child
- physical exam: toxic vs. non-toxic, vitals, growth, complete exams of the skin, HEENT, chest, abdomen, lymph nodes, genitalia
- investigations: guided by history, physical exam, and clinical suspicion

Evaluation of Neonates and Infants with Fever
- several protocols exist that attempt to identify neonates and young infants at low risk of serious bacterial infection (e.g. Rochester Criteria)
- such protocols are not as sensitive in the 1-28 d age group; therefore, febrile neonates should be considered high risk regardless of clinical presentation and laboratory findings
Management
- admit to hospital if appropriate
- treat the source if known
- replace fluid losses (e.g. from vomiting, diarrhea, etc.); maintenance fluid needs are higher in febrile child
- reassure parents that most fevers are benign and self-limited
- antipyretics (acetaminophen and/or ibuprofen) are not necessary in most cases, but can be given if child is uncomfortable

Acute Otitis Media

All of:
1. presence of middle ear effusion
2. presence of middle ear inflammation
3. acute onset of symptoms of middle ear effusion and inflammation

Epidemiology
- 60-70% of children have at least 1 episode of AOM before 3 yr of age
- 18 mo-6 yr most common age group
  - 22% of children in this age range will develop AOM in the first wk of a viral URI
  - one third of children have had ≥3 episodes by age 3; peak incidence January to April

Etiology
- S. pneumoniae: 32% of cases (decreasing since the introduction of PCV7 and PCV 13)
  - H. influenzae (non-typeable): >50% of refractory AOM
- M. catarrhalis: 14% of cases – less virulent
- GAS
- viral – more likely to spontaneously resolve
- less common - anaerobes (newborns) , Gram-negative enterics (infants)

Predisposing Factors
- Eustachian tube dysfunction/obstruction
- swelling of tubal mucosa: URTI, allergic rhinitis, chronic rhinosinusitis
- obstruction/infiltration of Eustachian tube ostium: adenoid hypertrophy (not due to obstruction but by maintaining a source of infection), barotrauma (sudden changes in air pressure)
- inadequate tensor palatini function: cleft palate (even aft. r repair)
- abnormal Eustachian tube: genetic syndromes such as DS, Crouzon, Apert
- disruption of action of cilia of Eustachian tube: Kartagener’s syndrome, CF
- immunosuppression/deficiency due to chemotherapy, steroids, DM, hypogammaglobulinemia, CF

Rochester Criteria – Developed to Identify Infants <60 d of Age with Fever at Low Risk of Serious Bacterial Infection

<table>

Past Health
- Born ≥37 wk
- Home with/before mom
- No hospitalizations
- No prior antibiotic use
- No prior treatment for unexplained hyperbilirubinemia
- No chronic disease
- Low risk (Rochester) criteria
  - Consider observation
  - Partial SWU2+Abx
  - without antibiotics
  - May consider empiric antibiotic5
  - Admit, Full SWU1, empiric antibiotic5

Clinical Assessment of AOM in Pediatrics

Purpose: To summarize the evidence on AOM diagnosis, treatment and the association of the heptavalent pneumococcal conjugate vaccine (PCV7) use with AOM microbiology.

Methods: Systematic review of diagnostic studies with a criterion standard, observational studies, and RCTs comparing AOM microbiology with and without PCV7, and RCTs assessing antibiotic treatment.

Results: 135 studies were included. Otoscopic findings of tympanic membrane bulging (positive likelihood ratio (PLR) 5.1 (2.2-11.9)) were associated with accurate diagnosis. Prevalence of S. pneumoniae decreased while that of H. influenzae increased pre vs. post-PCV7. Clinical success was higher with immediate ampicillin or amoxicillin versus placebo (73% vs. 60%; pooled rate difference 12%, 95% CI 5-18%; NNT 9, 95% CI 6-20). The risk of rash or diarrhea was increased by 3 to 5%. Some evidence suggested greater success with immediate versus delayed antibiotics. No significant differences were seen in terms of comparative effectiveness of antibiotics.

Conclusion: Otoscopic findings are critical to accurate AOM diagnosis. Antibiotics are somewhat effective than no treatment despite a higher accuracy of antibiotics. Prevalence of S. pneumoniae decreased while that of H. influenzae increased pre vs. post-PCV7. Clinical success was higher with immediate ampicillin or amoxicillin versus placebo (73% vs. 60%; pooled rate difference 12%, 95% CI 5-18%; NNT 9, 95% CI 6-20). The risk of rash or diarrhea was increased by 3 to 5%. Some evidence suggested greater success with immediate versus delayed antibiotics. No significant differences were seen in terms of comparative effectiveness of antibiotics.
Risk Factors

- prolonged bottle feeding, while laying down and/or shorter duration of breast feeding
- pacifier use
- second hand smoke
- crowded living conditions (day care/group child care facilities) or sick contacts
- family history of otitis media
- orofacial abnormalities
- immunodeficiency
- ethnicity – First Nations and Inuit
  - for recurrent AOM: lower levels of secretory IgA or persistent biofilms in the middle ear

Pathogenesis

- obstruction of Eustachian tube → air absorbed in middle ear → negative pressure (an irritant to middle ear mucosa) → edema of mucosa with exudate/effusion → infection of exudate from nasopharyngeal secretions

Clinical Features

- triad of otalgia, fever (especially in younger children), and conductive hearing loss
- rarely tinnitus, vertigo, and/or facial nerve paralysis
- otorrhea if tympanic membrane perforated
- infants/toddlers: ear-tugging (this alone is not a good indicator of pathology), hearing loss, balance disturbances (rare), irritable, poor sleeping, vomiting and diarrhea, anorexia
- otoscopy of TM: hyperemia, bulging, pus may be seen behind TM, loss of landmarks (e.g. handle and long process of malleus not visible)

Diagnosis

- most important criteria for AOM is a bulging TM (all children with bulging TM had AOM and only 8% of children with non-bulging TM had AOM) – Reference: Shaikh N, Hoberman A, Rockette HE, Kurs-Lasky M 2012

Management

- 1st line
  - amoxicillin 75-90 mg/kg/d divided into two doses: safe, effective, and inexpensive. Use high doses to overcome MIC for penicillin binding proteins (method of resistance)
  - if penicillin allergic: macrolide (clarithromycin, azithromycin – high resistance), trimethoprim-sulphamethoxazole (Bactrim®)
- 2nd line
  - amoxicillin-clavulanic acid (Clavulin®)
  - cephalosporins: cefuroxime axetil (Ceftin®), ceftriaxone (Rocephin®), cefaclor (Ceclor®), cefixime (Suprax®)
  - AOM deemed unresponsive if clinical signs/symptoms and otoscopic findings persist beyond 48 h of antibiotic treatment
  - use second line treatment for otitis-conjunctivitis syndrome (AOM with bacterial conjunctivitis) because *H. influenzae* and *M. catarrhalis* are more likely pathogens which are Beta lactamase producing, so Amoxicil is ineffective
  - symptomatic therapy: antipyretics/analgesics (e.g. acetaminophen), deconges ants (may relieve nasal congestion but does not treat AOM)
  - prevention: parent education about risk factors, pneumocooccal and influenza vaccines, surgery (e.g. tympanostomy tubes)
  - choice of surgery for recurrent AOM depends on whether local factors (Eustachian tube dysfunction) are responsible (use ventilation tubes), or regional disease factors (tonsillitis, adenoid hypertrophy, sinusitis) are responsible

Complications

- extracranial: hearing loss and speech delay (secondary to persistent middle ear effusion), TM perforation, extension of suppurative process to adjacent structures (mastoiditis, petrositis, labyrinthitis), cholesteatoma, facial nerve palsy, middle ear atelectasis, ossicular necrosis, vestibular dysfunction
- intracranial: meningitis, epidural and brain abscess, subdural empyema, lateral and cavernous sinus thrombosis, carotid artery thrombosis

Recommendations

- Management of AOM should include an assessment of pain; if pain is present, the clinician should recommend treatment to reduce pain.
- Prescribe antibiotic therapy for AOM (bilateral or unilateral) in children 6 mo and older with severe signs or symptoms (i.e. moderate or severe otalgia or otalgia for at least 48 h or temperature 39°C [102.2°F] or higher).
- For bilateral or unilateral AOM in children 6 mo through 23 mo of age without severe signs or symptoms (i.e. mild otalgia for less than 48 h and temperature less than 39°C [102.2°F]) either prescribe antibiotic therapy or offer observation with close follow-up based on joint decision-making with the parent(s)/caregiver(s). With observation ensure follow-up and begin antibiotic therapy if the child worsens or fails to improve within 48-72 h of onset of symptoms.
- Do NOT prescribe prophylactic antibiotics to reduce the frequency of episodes of AOM in children with recurrent AOM.
- Recommend annual influenza vaccine and pneumococcal conjugate vaccine to all children according to vaccination schedule.
**Otitis Media with Effusion**

**Definition**
- presence of fluid in the middle ear without signs or symptoms of ear infection

**Epidemiology**
- most common cause of pediatric hearing loss
- not exclusively a pediatric disease
- follows AOM frequently in children
- middle ear effusions have been shown to persist following an episode of AOM for 1 mo in 40% of children, 2 mo in 20%, and >3 mo in 10%

**Risk Factors**
- same as AOM

**Clinical Features**
- conductive hearing loss ± tinnitus
- fullness – blocked ear
- ± pain, low grade fever
- otoscopy of TM
  - discoloration – amber or dull grey
  - meniscus fluid level behind TM
  - air bubbles
  - retraction pockets/TM atelectasis
  - flat tympanogram
- most reliable finding with pneumatic otoscopy is immobility

**Treatment**
- expectant: 90% resolve by 3 mo
- document hearing loss with audiogram (see Otolaryngology Figure 16B and Figure 17B, OT10-11)
- no statistical proof that antihistamines, decongestants, antibiotics clear disease faster
- surgery: myringotomy ± ventilation tubes ± adenoidectomy (if enlarged or on insertion of second set of tubes after first set falls out)
- ventilation tubes to equalize pressure and drain ear

**Complications of OME**
- hearing loss, speech delay, learning problems in young children
- chronic mastoiditis
- ossicular erosion
- cholesteatoma especially when retraction pockets involve pars flaccida
- retraction of tympanic membrane, atelectasis, ossicular fixation

</tr>
</tbody>
</table>
**Infectious Mononucleosis**

**Definition**
- Systemic viral infection caused by EBV with multivisceral involvement; often called "the great imitator"

**Epidemiology**
- Peak incidence between 15-19 yr old
- ~50% of children in developed countries have a primary EBV infection by 5 yr old, but <10% of children develop clinical infection

**Etiology**
- EBV: a member of herpesviridae
- Transmission is mainly through infected saliva ("kissing disease") and sexual activity (less commonly); incubation period of 1-2 mo

**Risk Factors**
- Infectious contacts, sexually active, multiple sexual partners in the past

**History**
- Prodrome: 2-3 d of malaise, anorexia
- Infants and young children: often asymptomatic or mild disease
- Older children and adolescents: malaise, fatigue, fever, sore throat, abdominal pain (often LUQ), headache, myalgia

**Physical Exam**
- Classic triad: febrile, generalized non-tender lymphadenopathy, pharyngitis/tonsillitis (exudative)
- ± hepatosplenomegaly
- ± periocular edema, ± rash (urticarial, maculopapular, or petechial) – more common after inappropriate treatment with β-lactam antibiotics
- Any “-itis” (including arthritis, hepatitis, nephritis, myocarditis, encephalitis, etc.)

**Investigations**
- Heterophil antibody test (Monospot® test)
  - 85% sensitive in adults and older children, but only 50% sensitive if <4 yr of age
  - False positive results with HIV, SLE, lymphoma, rubella, parvovirus
- EBV titres
- CBC and differential, blood smear: reactive lymphocytes, lymphocytosis, Downey cells ± anemia ± thrombocytopenia
- Throat culture to rule out streptococcal pharyngitis

**Management**
- Supportive: adequate rest, hydration, saline gargles, and analgesics for sore throat
- Splenic enlargement is often not clinically apparent so all patients should avoid contact sports for 6-8 wk
- If airway obstruction secondary to nodal and/or tonsillar enlargement is present (especially younger children), admit for steroid therapy
- Acyclovir does NOT reduce duration of symptoms or result in earlier return to school/work

**Prognosis**
- Most acute symptoms resolve in 1-2 wk, though fatigue may last for months
- Short-term complications: splenic rupture, Guillain-Barré syndrome

**Infectious Pharyngitis/Tonsillitis**

**Definition**
- Inflammation of the pharynx, especially the tonsils if present, causing a sore throat

**Etiology**
- Viral (~80%): adenoviruses, enteroviruses, coxsackie, upper respiratory tract viruses, EBV, CMV
- Bacterial (~20%): mainly GAS, M. pneumoniae (older children), N. gonorrhoeae (sexually active), C. diphtheriae (unvaccinated), Fusobacterium necrophorum (anaerobe causing Lemierre syndrome)
- Fungal: Candida

**Epidemiology**
- Season: GAS pharyngitis more common in late winter or early spring; viral all year long
- Age: GAS pharyngitis peak incidence at 5-12 yr of age and uncommon <3 yr; viral pharyngitis affects all ages

**History**
- GAS: sore throat (may be severe), fever, malaise, headache, abdominal pain, N/V, absence of other URTI symptoms
- Viral: sore throat (often mild), conjunctivitis, cough, rhinorrhea, hoarseness, diarrhea, flu-like symptoms (fever, malaise, myalgia)
Physical Exam
- GAS: febrile, pharyngeal/tonsillar erythema and exudates, enlarged (>1 cm) and tender anterior cervical lymph nodes, palatal petechiae, strawberry tongue, scarlatiniform rash
- viral: afebrile, mild tonsillar exudates, minor and non-tender adenopathy, viral exanthems

Investigations
- no single sign or symptom reliably identifies GAS as the causative organism in children with sore throat
- scores are used to predict if throat culture will be positive (e.g. McIsaac Criteria)
  - these score systems have not been found to be sensitive or specific enough to diagnose GAS in children and adolescents with sore throat
- suspected diagnosis of GAS pharyngitis should be confirmed with a rapid streptococcal antigen test and a follow-up throat culture if the rapid test is negative

Management
- antibiotics (for GAS/S. pyogenes)
  - penicillin V or amoxicillin or erythromycin (if penicillin allergy) x 10 d
  - can prevent rheumatic fever if given within 9 d of symptoms; does NOT alter risk of post-streptococcal GN
- supportive: hydration and acetaminophen for discomfort due to pain and/or fever
- follow-up: if uncomplicated course, no follow-up or post antibiotic throat cultures needed
- prophylaxis: consider tonsillectomy for proven, recurrent streptococcal tonsillitis

Complications
- preventable with antibiotics: AOM, sinusitis, cervical adenitis, mastoiditis, retropharyngeal/peritonsillar abscess, sepsis
- immune-mediated complications: scarlet fever, acute rheumatic fever, post-streptococcal GN, reactive arthritis, pediatric autoimmune neuropsychiatric disorder associated with group A streptococci (i.e. PANDAS)

SCARLET FEVER
- diffuse erythematous eruption
- delayed-type hypersensitivity reaction to pyrogenic exotoxin produced by GAS
- acute onset of fever, sore throat, strawberry tongue
- 24-48 h after pharyngitis, rash begins in the groin, axillae, neck, antecubital fossa; Pastia's lines may be accentuated in flexural areas
- within 24 h, sandpaper rash becomes generalized with perioral sparing, non-pruritic, non-painful, blanchable
- rash fades after 3-4 d, may be followed by desquamation
- treatment is penicillin, amoxicillin, or erythromycin x 10 d

RHEUMATIC FEVER
- inflammatory disease due to antibody cross-reactivity following GAS infection
- affects ~1:10,000 children in developed world; much more prevalent in developing nations; peak incidence at 5-15 yr of age
- mainly a clinical diagnosis based on Jones Criteria (revised)
  - requires 2 major OR 1 major and 2 minor PLUS evidence of preceding strep infection (history of scarlet fever, GAS pharyngitis culture, positive rapid Ag detection test, ASOTs)
- treatment: penicillin or erythromycin for acute course x 10 d, prednisone if severe carditis
- secondary prophylaxis with daily penicillin or erythromycin
- complications
  - acute: myocardiitis, conduction system aberrations (sinus tachycardia, atrial fibrillation), valvulitis (acute MR), pericarditis
  - chronic: valvular heart disease (mitral and/or aortic insufficiency/stenosis), infectious endocarditis ± thromboembolic phenomenon
  - onset of symptoms usually after 10-20 yr latency from acute carditis of rheumatic fever

POST-STREPTOCOCCAL GLOMERULONEPHRITIS
- most common in children aged 4-8 yr old; M>F
- antigen-antibody mediated complement activation with diffuse, proliferative GN
- occurs 1-3 wk following initial GAS infection (skin or throat)
- clinical presentation varies from asymptomatic, microscopic and macroscopic hematuria (cola-coloured urine) to all features of nephritic syndrome (see Nephritic Syndrome, P72)
- diagnosis is confirmed with elevated serum antibody titres against streptococcal antigens (ASOT, anti-DNase B), low serum complement (C3)
- management
  - symptomatic: fluid and sodium restrictions; loop diuretics for HTN and edema
  - in severe cases, may require dialysis if renal function significantly impaired
  - treat with penicillin or erythromycin if evidence of persistent GAS infection
- 95% of children recover completely within 1-2 wk; 5-10% have persistent hematuria
Meningitis

Definition
• inflammation of the meninges surrounding the brain and spinal cord

Epidemiology
• peak age: 6-12 mo; 90% of cases occur in children <5 yr old

Etiology
• viral: enteroviruses, HSV
• bacterial: age-related variation in specific pathogens
• fungal and parasitic meningitis also possible
• most often due to hematogenous spread or direct extension from a contiguous site

Risk Factors
• unvaccinated
• immunocompromise: asplenia, DM, HIV, prematurity
• recent or current infections: AOM, sinusitis, orbital cellulitis
• neuroanatomical: congenital defects, dermal sinus, neurosurgery, cochlear implants, recent head trauma
• exposures: day care centres, household contact, recent travel

History
• signs and symptoms variable and dependent on age, duration of illness, and host response to infection
• infants: fever, lethargy, irritability, poor feeding, vomiting, diarrhea, respiratory distress, seizures
• children: fever, headache, photophobia, N/V, confusion, back/neck pain/stiffness, lethargy, irritability

Physical Exam
• infants: toxic, hypothermia, bulging anterior fontanelle, respiratory distress, apnea, petechial/purpuric rash, jaundice
• children: toxic, LOC, nuchal rigidity, Kernig’s and Brudzinski’s signs, focal neurologic findings, petechial/purpuric rash

Investigations
• blood work: CBC, electrolytes, Cr, BUN, glucose, C&S
• LP required for definitive diagnosis
  • Gram stain, bacterial C&S, WBC count and differential, RBC count, glucose, protein concentration
  • acid-fast stain if suspect TB
  • PCR for specific bacteria if available (helpful if already treated with antibiotics)
  • urinalysis and urine C&S in infants, Gram stain and culture of petechial/purpuric lesions
  • HSV and enterovirus PCR if suspected

Management
• supportive care
  • preservation of adequate cerebral perfusion by maintaining normal BP and managing ICP
  • close monitoring of fluids, electrolytes, glucose, acid-base disturbances, coagulopathies
• bacterial meningitis
  • if suspected or cannot be excluded, commence empiric antibiotic therapy while awaiting cultures or if LP contraindicated or delayed
  • isolation with appropriate infection control procedures until 24 h after culture-sensitive antibiotic therapy
  • fluid restrict if any concern for SIADH
  • hearing test
• report to Public Health; prophylactic antibiotics for close contacts of Hib and N. meningitidis meningitis

</tr>
</tbody>
</table>

- **viral meningitis**
  - mainly supportive (except for HSV)
  - acyclovir for HSV meningitis
  - report to Public Health
- prophylaxis: appropriate vaccinations significantly decrease incidence of bacterial meningitis (see *Routine Immunization*, P4)

### Complications
- mortality: neonate 15-20%, children 4-8%; pneumococcus > meningococcus > Hib
- acute: SIADH, subdural effusion/empyema, brain abscess disseminated infection (osteomyelitis, septic arthritis, abscess), shock/DIC
- chronic: hearing loss, neuromotor/cognitive delay, learning disabilities, neurological deficit, seizure disorder, hydrocephalus

### Mumps

#### Definition
- acute, self-limited viral infection that is most commonly characterized by adenitis and swelling of the parotid glands

#### Epidemiology
- incidence in Ontario has declined since introduction of two-dose MMR vaccination schedule
- average of 25 reported cases per yr
- majority of reported cases in children between 5-10 yr of age

#### Etiology
- mumps virus (RNA virus of the genus Rubulavirus in the Paramyxoviridae family)
- transmission via respiratory droplets, direct contact fomites
- incubation period: 14-25 d
- infectivity period: 7 d pre-parotitis to 5 d post-parotitis
- upper respiratory tract lymph nodes salivary glands, gonads, pancreas, meninges, kidney, heart, thyroid

#### History
- non-specific prodome of fever, headache, malaise, myalgias (especially neck pain)
- usually followed within 48 h by parotid swelling secondary to parotitis (bilateral, preauricular, ear pushed up and out)
- parotid gland is tender and pain worsened with spicy or sour foods
- one third of infections do not cause clinically apparent salivary gland swelling and may simply present as an URTI

#### Investigations
- clinical diagnosis, but may be confirmed with IgM positive serology within 4 wk of acute infection
- may also use PCR or viral cultures from oral secretions, urine, blood, and CSF
- blood work: CBC (leukopenia with relative lymphocytosis), serum amylase (elevated)

#### Management
- mainly supportive: analgesics, antipyretics warm or cold packs to parotid may be soothing
- admit to hospital if serious complications (meningitis, pancreatitis)
- droplet precautions recommended until 5 d after onset of parotid swelling
- prophylaxis: routine vaccination (see *Routine Immunization*, P4)

#### Complications
- common: aseptic meningitis, orchitis/oophoritis
- less common: encephalitis, pancreatitis, thyroiditis, myocardiitis, arthritis, GN, ocular complications, hearing impairment
Pertussis

**Definition**
- prolonged respiratory illness characterized by paroxysmal coughing and inspiratory “whoop”

**Epidemiology**
- ∼10 million children <1 yr old affected worldwide, causes up to 400,000 deaths/yr
- greatest incidence among children <1 yr (not fully immunized) and adolescents (waning immunity)

**Etiology**
- *Bordetella pertussis*: Gram negative pleomorphic rod
- highly contagious; transmitted via respiratory droplets released during intense coughing
- incubation period: 6-20 d; most contagious during catarrhal phase but may remain contagious for weeks after

**History**
- prodromal catarrhal stage
  - lasts 1-7 d; URTI symptoms (coryza, mild cough, sneezing) with NO or LOW-GRADE fever
- paroxysmal stage
  - lasts 4-6 wk; characterized by paroxysms of cough (“100 day cough”), sometimes followed by inspiratory whoop (“whooping cough”)
  - infants <6 mo may present with post-tussive apnea, whoop is often absent
  - onset of attacks precipitated by yawning, sneezing, eating, physical exertion
  - ± post-tussive emesis, may become cyanotic before whoop
  - vomiting after whooping episodes
- convalescent stage
  - lasts 1-2 wk; characterized by occasional paroxysms of cough, but decreased frequency and severity
  - non-infectious but cough may last up to 6 mo

**Investigations**
- NP specimen using aspirate or NP swab
  - gold standard: culture using special media (Regan-Lowe agar)
  - PCR to detect pertussis antigens
- blood work: CBC (lymphocytosis) and serology (antibodies against *B. pertussis*)

**Management**
- admit if paroxysms of cough are associated with cyanosis and/or apnea and give O₂
- supportive care
  - antimicrobial therapy indicated if *B. pertussis* isolated, or symptoms present for <21 d
    - use macrolide antibiotics (azithromycin, erythromycin, or clarithromycin)
- droplet isolation until 5 d of treatment and report to Public Health
- prophylaxis
  - macrolide antibiotics for all household contacts
  - prevention with vaccination in infants and children (Pentacel®), and booster in adolescents (Adacel®) *(see Routine Immunization, P4)*

**Complications**
- pressure-related from paroxysms: subconjunctival hemorrhage, rectal prolapse, hernias, epistaxis
- respiratory: sinusitis, pneumonia, aspiration, atelectasis, pneumomediastinum, pneumothorax, alveolar rupture
- neurological: seizures (~3%), encephalopathy, ICH
- mortality: ~0.3%; highest risk in infants <6 mo old

Pneumonia
- see Respirology, P80

Periorbital (Preseptal) and Orbital Cellulitis
- see Ophthalmology, OP9

Sexually Transmitted Infections
- see Family Medicine, FM42 and Gynecology, GY27
Sinusitis

- see Family Medicine, FM43
- complication of ≤10% of URTIs in children
- clinical diagnosis
- diagnostic imaging is NOT required to confirm diagnosis in children
  - routine CT not recommended, but consider if suspect complications of sinusitis, persistent/ recurrent disease, need for surgery
- antibiotic therapy for all children (although nearly half resolve spontaneously within 4 wk)
- complications: preseptal/orbital (preseptal/orbital cellulitis, orbital abscess, osteomyelitis, etc.), intracranial (meningitis, abscess, etc.), Pott's Puffy tumour

Urinary Tract Infection

Definition
- infection of the urinary bladder (cystitis) and/or kidneys (pyelonephritis)

Epidemiology
- overall prevalence in infants and young children presenting with fever is 7%
- <4-6 wk old: more common in boys
- >1 yr old: females have two- to four-fold higher prevalence

Etiology
- majority (>95%) have a single cause (~70% E. coli)
- Gram-negative bacilli: E. coli, Klebsiella, Proteus, Enterobacter, Pseudomonas
- Gram-positive cocci: S. saprophyticus, Enterococcus

Risk Factors
- non-modifiable: female gender, Caucasian, previous UTIs, family history
- modifiable: urinary tract abnormalities (VUR, neurogenic bladder, obstructive uropathy, posterior urethral valve), dysfunctional voiding, repeated bladder catheterization, uncircumcised males, labial adhesions, sexually active, constipation, toilet training

History
- infants and young child: often just fever or non-specific symptoms (poor feeding, irritability, FTT, jaundice, f <28 d old, vomiting)
- older child: fever, urinary symptoms (dysuria, urgency, frequency, incontinence, hematuria), abdominal, and/or flank pain

Physical Exam
- infants and young child: toxic vs. non-toxic, febrile, FTT, jaundice; look for external genitalia abnormalities (phimosis, labial adhesions) and lower back signs of occult myelodysplasia (e.g. hair tufts), which may be associated with neurogenic bladder
- older child: febrile, suprapubic and/or CVA tenderness, abdominal mass (enlarged bladder or kidney); may present with short stature, FTT, or HTN secondary to renal scarring from previously unrecognized or recurrent UTIs

Investigations
- sterile urine specimen
  - clean catch, catheterization, suprapubic aspiration or ‘Tap and Rub’ technique
  - urinalysis (leukocyte esterase, nitrites, erythrocytes, hemoglobin), microscopy (bacteria and leukocytes, erythrocytes), C&S
- diagnosis established if urinalysis suggests infection AND if ≥50,000 colony-forming units per mL of a uropathogen cultured

Management
- admit if: <2 mo old, urosepsis, persistent vomiting, inability to tolerate oral medication, moderate-severe dehydration, immunocompromised complex urologic pathology, inadequate follow-up, failure to respond to outpatient treatment
- supportive care: maintenance of hydration and adequate pain control
- antibiotics
  - base on local antimicrobial susceptibility patterns
  - commence broad empiric therapy until results of urine C&S known, and then tailor as appropriate
  - neonates: IV ampicillin and gentamicin
  - infants and older children: oral antibiotics (based on local E. coli sensitivity) if outpatient; IV ampicillin and gentamicin if inpatient
  - duration 7-10 d
- imaging
  - renal and bladder U/S for all febrile infants (<2 yr) with UTIs looking for anatomical abnormalities, hydromephrosis, abscess
  - VCUG not recommended after 1st febrile UTI unless U/S reveals hydronephrosis, obstructive uropathies or other signs suggestive of high-grade VUR

Features Suggestive of Pyelonephritis
- High-grade fever
- Flank or high abdominal pain
- CVA tenderness on palpation

Bagged urine specimen not useful for ruling in UTI (high false positive rate >85%), but useful for ruling out UTI (high sensitivity)
- follow-up: outpatients to return in 24-48 h if no clinical response and seek prompt medical evaluation for future febrile illnesses
- prophylaxis: generally not recommended unless higher grades of VUR

**Complications**
- long-term morbidity: focal renal scarring develops in 8% of patients; long-term significance unknown

### Neonatology

#### Gestational Age and Size

**Definitions**
- classification by GA
  - preterm: <37 wk
  - near-term: 35-37 wk
  - term: 37-42 wk
  - post-term: >42 wk
- classification by birth weight
  - SGA: 2 SD < mean weight for GA or <10th percentile
  - AGA: within 2 SD of mean weight for GA
  - LGA: 2 SD > mean weight for GA or >90th percentile

**Table 22. Abnormalities of Gestational Age and Size**

**Routine Neonatal Care**

1. erythromycin ointment: applied to both eyes for prophylaxis of ophthalmia neonatorum (of questionable efficacy)
2. vitamin K IM: prophylaxis against HDNB
3. newborn screening tests in Ontario
   - in Ontario, newborn screening tests for metabolic disorders (amino acid disorders, organic acid disorders, fatty acid oxidation defects, biotinidase deficiency, galactosemia)
   - blood disorders (SCD, other hemoglobinopathies)
   - endocrine disorders (CAH, congenital hypothyroidism)
   - others (CF, severe combined immunodeficiency)
   - congenital hearing loss
4. if mother Rh negative: send cord blood for blood group and direct antiglobulin test
5. if mother hepatitis B surface antigen positive: HBIG and start hepatitis B vaccine series
Neonatal Resuscitation

- assess Apgar score at 1 and 5 min
- if <7 at 5 min then reassess q5min, until >7
- do not wait to assign Apgar score before initiating resuscitation

Table 23. Apgar Score

Initial Resuscitation

- anticipation: know maternal history, history of pregnancy, labour, and delivery
- steps to take for all infants
  - warm (radiant heater, warm blankets) and dry the newborn (remove wet blankets)
  - position and clear airway (“sniffing” position)
  - stimulate infant: rub lower back gently or flick soles of feet EXCEPT if meconium present (in which case tracheal suction first)
- assess breathing and heart rate

Approach to the Depressed Newborn

- a depressed newborn lacks one or more of the following characteristics of a normal newborn
  - pulse >100 bpm
  - cries when stimulated
  - actively moves all extremities
  - has a good strong cry
- approximately 10% of newborn babies require assistance with breathing after delivery

Use of 100% Oxygen in Neonatal Resuscitation

Findings from animal and theoretical studies have suggested potential adverse effects with the administration of 100% oxygen. However, given available data is limited in general and only obtained from newborn samples, the 2015 neonatal resuscitation guidelines have provided the following recommendation: “Since an oxygen saturation of 100% may correspond to a PaO2 anywhere between ~80 and 500 mm Hg, in general it is appropriate to wean the FIO2 for a saturation of 100%, provided the oxyhemoglobin saturation can be maintained ≥94%.” (Class IIb, LOE C).

Corrective Actions for PPV in Neonatal Resuscitation

- MR SOPA
  - Mask readjustment
  - Reposition airway
  - Suction mouth and nose
  - Open mouth
  - Pressure increase
  - Alternative airway
Common Conditions of Neonates

Apnea

Definition
- “periodic breathing”: normal respiratory pattern seen in newborns in which periods of rapid respiration are alternated with pauses lasting 5-10 s
- “apnea”: absence of respiratory gas flow for >20 s (or less if associated with bradycardia or desaturation)
  - 3 types:
    - central: no chest wall movement, no signs of obstruction
    - obstructive: chest wall movement continues against obstructed upper airway, no airflow
    - mixed: combination of central and obstructive apnea

Differential Diagnosis
- in term infants, apnea requires full workup as it can be associated with sepsis
- other causes
  - CNS
  - apnea of prematurity (<34 wk): combination of CNS immaturity and obstructive apnea; resolves by 36 wk GA; diagnosis of exclusion
  - seizures
  - ICH
  - hypoxic injury
  - infectious: sepsis, meningitis, NEC
  - GI: GERD, aspiration with feeding
  - metabolic: hypoglycemia, hyponatremia, hypocalcemia, inborn error of metabolism
  - cardiovascular: anemia, hypovolemia, PDA, heart failure
  - medications: morphine

Management
- O2, ventilatory support, maintain normal blood gases
- tactile stimulation
- correct underlying cause
- medications: methylxanthines (caffeine) stimulate the CNS and diaphragm and are used for apnea of prematurity (not in term infants)

Bleeding Disorders in Neonates

Clinical Presentation
- oozing from the umbilical stump, excessive bleeding from peripheral venipuncture/heel stick sites/IV sites, large caput succedaneum, cephalohematomas (in absence of significant birth trauma), subgaleal hemorrhage and prolonged bleeding following circumcision

Etiology
- 4 major categories
  - increased platelet destruction: maternal ITP or SLE, infection/sepsis, DIC, neonatal alloimmune thrombocytopenia, autoimmune thrombocytopenia
  - decreased platelet production/function: pancytopenia, bone marrow replacement, Fanconi anemia, Trisomy 13 and 18
  - metabolic: congenital thyrotoxicosis, inborn error of metabolism
  - coagulation factor deficiencies (see Hematology, H31): hemophilia A/B, HDNB
NEONATAL ALLOIMMUNE THROMBOCYTOPENIA

**Epidemiology**
- 1 per 4,000-5,000 live births

**Pathophysiology**
- platelet equivalent of Rh disease of the newborn
- occurs when mother is negative for HPA and fetus is positive
- development of maternal IgG antibodies against HPA antigens on fetal platelets

**Clinical Presentation**
- petechiae, purpura, thrombocytopenia in otherwise healthy neonate
- severe disease can lead to intracranial bleeding

**Diagnosis**
- maternal and paternal platelet typing and identification of platelet alloantibodies

**Treatment**
- IVIg to mother prenatally starts in second trimester ± steroids ± fetal platelet transfusions
- treat neonate with IVIg
- if transfusion required should be with washed maternal platelets or donor HPA negative platelets

AUTOIMMUNE THROMBOCYTOPENIA

**Pathophysiology**
- caused by antiplatelet antibodies from maternal ITP or SLE
- passive transfer of antibodies across placenta

**Clinical Presentation**
- similar presentation to neonatal alloimmune thrombocytopenia, but thrombocytopenia usually less severe

**Treatment**
- steroids to mother for 10-14 d prior to delivery or IVIg to mother before delivery
- treat neonate with IVIg (usually if platelets <60,000)
- transfusion of infant with maternal/donor platelets only in severe cases, as antibodies will destroy transfused platelets

HEMORRHAGIC DISEASE OF THE NEWBORN

**Pathophysiology**
- caused by vitamin K deficiency
- factors II, VII, IX, X are vitamin K-dependent, therefore both PT and PTT are abnormal

**Etiology and Clinical Presentation**
- neonates at risk of vitamin K deficiency if: vitamin K poorly transferred across the placenta; maternal use of antiepileptics; insufficient bacterial colonization of colon at birth to synthesize vitamin K; breastfed (vitamin K intake inadequate in breastfed infants)
- vitamin K poorly transferred across the placenta
- insufficient bacterial colonization of colon at birth to synthesize vitamin K
- vitamin K intake inadequate in breastfed infants
- maternal use of antiepileptics is an additional risk factor
- neonate may present with hematomas, ICH (causing apnea or seizures), internal bleeding, hematuria, bruising, prolonged bleeding (often from mucous membranes, umbilicus, circumcision, and venipunctures)

**Prevention**
- vitamin K IM administration at birth to all newborns

---

**Bronchopulmonary Dysplasia**

**Definition**
- also known as chronic lung disease
- clinically defined as O₂ requirement for >28 d plus persistent need for oxygen and/or ventilatory support at 36 wk corrected GA
- damage to developing lungs with prolonged intubation/ventilation, high levels O₂, infections

**Investigations**
- CXR findings may demonstrate decreased lung volumes areas of atelectasis, signs of inflammation, and hyperinflation
Treatment
- no good treatments
- gradual wean from ventilator, optimize nutrition
- dexamethasone may help decrease inflammation and encourage weaning, but use of dexamethasone is associated with increased risk of adverse neurodevelopmental outcomes

Prognosis
- chronic respiratory failure may lead to pulmonary HTN, poor growth, and right-sided heart failure
- patients with bronchopulmonary dysplasia may continue to have significant impairment and deterioration in lung function late into adolescence
- some lung abnormalities may persist into adulthood including airway obstruction, airway hyper-reactivity, and emphysema
- associated with increased risk of adverse neurodevelopmental outcomes

Cyanosis

Management
- ABGs
  - elevated CO₂ suggests respiratory cause
  - hyperoxia test (to distinguish between cardiac and respiratory causes of cyanosis): get baseline PaO₂ in room air, then PaO₂ on 100% O₂ for 10-15 min
    - PaO₂ <150 mmHg: suggests cyanotic CHD or possible PPHN (see Cardiology, P16)
    - PaO₂ >150 mmHg: suggests cyanosis likely due to respiratory or non cardiac cause
  - CXR: look for respiratory abnormalities (pneumothorax, respiratory tract malformations, evidence of shunting, pulmonary infiltrates) and cardiac abnormalities (cardiomegaly, abnormalities of the great vessels)

Diaphragmatic Hernia

Definition
- developmental defect of the diaphragm with herniation of abdominal organs into thorax
- associated with pulmonary hypoplasia and PPHN

Clinical Presentation
- respiratory distress, cyanosis
- scaphoid abdomen and barrel-shaped chest
- affected side dull to percussion and breath sounds absent, may hear bowel sounds instead
- heart sounds shifted to contralateral side
- asymmetric chest movements, trachea deviated away from affected side
- may present outside of neonatal period
- often associated with other anomalies (cardiovascular, CNS, chromosomal abnormalities)
- CXR: bowel loops in thorax (usually left side), displaced mediastinum
Treatment
- immediate intubation required at birth: DO NOT bag mask ventilate because air will enter stomach and further compress lungs
- place large bore orogastric tube to decompress bowel
- initial stabilization and management of pulmonary hypoplasia and PPHN, hemodynamic support and surgery when stable

Hypoglycemia

Definition
- glucose <2.6 mmol/L

Etiology
- decreased carbohydrate stores: premature, SGA, RDS, maternal HTN
- endocrine: hormonal deficiencies (GH, cortisol, epinephrine), insulin excess (infant of diabetic mother, Beckwith-Wiedemann syndrome/islet cell hyperplasia), HPA axis suppression (panhypopituitarism)
- inborn errors of metabolism: fatty acid oxidation defects, galactosemia
- miscellaneous: sepsis, hypothermia, polycythemia

Clinical Findings
- signs often non-specific and subtle: lethargy, poor feeding, irritability, tremors, apnea, cyanosis, seizures

Management
- identify and monitor infants at risk (pre-feed blood glucose checks)
- begin oral feeds as soon as possible after birth and ensure regular feeds
- if significant and/or symptomatic hypoglycemia, provide glucose IV and titrate according to blood sugar levels
- if persistent hypoglycemia or no predisposing cause, send "critical blood work" during an episode of hypoglycemia: ABG, ammonia, β-hydroxybutyrate, cortisol, free fatty acids, GH, insulin, lactate, urine dipstick for ketones

Intraventricular Hemorrhage

Definition
- hemorrhage originating in the periventricular subependymal germinal matrix

Epidemiology
- incidence and severity inversely proportional to GA
- 50% of IVH occurs within 8 h of birth; 90% occurs by day 3

Risk Factors
- preterm infants, hemodynamic instability, RDS, coagulopathy

Clinical Presentation
- many infants with IVH are asymptomatic
- subtle signs: apnea, bradycardia, changes in tone or activity, altered LOC
- catastrophic presentation: bulging fontanelle, sudden drop in hematocrit, acidosis, seizures, hypotension

Classification
- Papile classification
- parenchymal hemorrhage may also occur in the absence of IVH
- routine head U/S screening of all preterm infants <32 wk or <1,500 g gestation throughout NICU stay
- consider MRI at term for extremely LBW infants

Management of Acute Hemorrhage
- supportive care to maintain blood volume and acid-base status
- avoid fluctuations in blood pressure and cerebral blood flow
- follow-up with serial imaging

Prognosis
- outcome depends on grade of IVH
- short-term sequelae for severe IVH: mortality, extension of bleed, posthemorrhagic hydrocephalus, posthemorrhagic infarction, cyst formation
- possible long-term major neurological sequelae: CP, cognitive deficits, motor deficits, visual and hearing impairment
- Grades I and II hemorrhages have a relatively favourable prognosis
- greatest morbidity and mortality is seen with Grade IV hemorrhage and posthemorrhagic hydrocephalus requiring ventriculoperitoneal shunt placement
Jaundice

Clinical Presentation
- jaundice is visible at serum bilirubin levels of 85-120 µmol/L; visual assessment is often misleading
- look at sclera, tip of nose in natural light
jaundice more severe/prolonged (due to increased retention of bilirubin in the circulation) with:
prematurity, acidosis, hypoalbuminemia, dehydration, hemolysis

Jaundice is very common – 60% of term newborns develop visible jaundice

Jaundice in the first 24 h of life and conjugated hyperbilirubinemia are always pathological

Jaundice must be investigated if:
- It occurs within 24 h of birth
- Conjugated hyperbilirubinemia is present
- Unconjugated bilirubin rises rapidly or is excessive for patient’s age and weight
- Persistent jaundice lasts beyond 1-2 wk of age

Figure 13. Approach to neonatal hyperbilirubinemia

PHYSIOLOGIC JAUNDICE

Epidemiology
- term infants: onset 3-4 d of life, resolution by 10 d of life
- premature infants: higher peak and longer duration

Pathophysiology
- increased hematocrit and decreased RBC lifespan
- immature glucuronyl transferase enzyme system (slow conjugation of bilirubin)
- increased enterohepatic circulation

Breastfeeding Jaundice
- common; due to a lack of milk production → dehydration → exaggerated physiologic jaundice

Breast Milk Jaundice
- 1 per 200 breastfed infants
- glucuronyl transferase inhibitor found in breast milk
- onset 7 d of life, peak at 2-3 wk of life, usually resolved by 6 wk

Table 26. Risk Factors for Jaundice

</tbody>
</table>
PATHOLOGIC JAUNDICE
• all cases of conjugated hyperbilirubinemia; some cases of unconjugated hyperbilirubinemia are pathologic

Investigations
• unconjugated hyperbilirubinemia
  • hemolytic workup: CBC, reticulocyte count, blood group (mother and infant), peripheral blood smear, Coombs test
  • if baby is unwell or has fever: septic workup (CBC and differential, blood and urine cultures ± LP, CXR)
  • other: G6PD screen (especially in males), TSH
• conjugated hyperbilirubinemia must be investigated without delay
  • consider liver enzymes (AST, ALT), coagulation studies (PT, PTT), serum albumin, ammonia, TSH, TORCH screen, septic workup, galactosemia screen (erythrocyte galactose-1-phosphate uridyltransferase levels), metabolic screen, abdominal U/S, HIDA scan, sweat chloride
• predicting occurrence of severe hyperbilirubinemia (Refer to: http://www.cps.ca/documents/position/hyperbilirubinemia-newborn)
  • either TSB or TcB concentration be measured in all infants between 24 h and 72 h of life
  • if the infant does not require immediate treatment, results should be plotted on predictive nomogram to determine the risk of progression to severe hyperbilirubinemia

TREATMENT OF UNCONJUGATED HYPERBILIRUBINEMIA
• to prevent kernicterus
  • breastfeeding does not usually need to be discontinued, ensure adequate feeds and hydration
  • lactation consultant support, mother to pump after feeds
  • treat underlying causes (e.g. sepsis)
    • insoluble unconjugated bilirubin is converted to excretable form via photoisomerization
    • serum bilirubin should be monitored during and immediately after therapy (risk of rebound because photoisomerization reversible when phototherapy discontinued)
    • contraindicated in conjugated hyperbilirubinemia: results in “bronzed” baby
    • side effects: skin rash, diarrhea, eye damage (eye shield used routinely for prevention), dehydration
    • use published guidelines and nomogram for initiation of phototherapy
  • exchange transfusion
    • indications: high bilirubin levels as per published graphs based on age, weeks gestation
    • most commonly performed for hemolytic disease and G6PD deficiency
    • use of IVIg in case of severe hyperbilirubinemia (DAT+) becoming evidence-based practice

KERNICTERUS

Etiology
• unconjugated bilirubin concentrations exceed albumin binding capacity and bilirubin is deposited in the brain resulting in permanent damage (typically basal ganglia or brainstem)
• incidence increases as serum bilirubin levels increase above 340 µmol/L
• can occur at lower levels in presence of sepsis, meningitis, hemolysis, hypoxia, acidosis, hypothermia, hypoglycemia, and prematurity

Clinical Presentation
• up to 15% of infants have no obvious neurologic symptoms
  • early stage: lethargy, hypotonia, poor feeding, emesis (bilirubin encephalopathy)
  • mid stage: hypertonia, high pitched cry, opisthotonic posturing (back arching), bulging fontanelle, seizures, pulmonary hemorrhage
  • late stage (first year and beyond)
    • hypotonia delayed motor skills, extrapyramidal abnormalities (choreoathetoid CP), gaze palsy, mitral regurgitation, sensorineural hearing loss

Prevention
• exchange transfusion, IVIg if indicated
**BILIARY ATRESIA**

**Definition**
- atresia of the extrahepatic bile ducts which leads to cholestasis and increased conjugated bilirubin after the first wk of life
- progressive obliterative cholangiopathy

**Epidemiology**
- incidence: 1:10,000-15,000 live births
- associated anomalies in 10-35% of cases: situs inversus, congenital heart defects, polysplenia

**Clinical Presentation**
- dark urine, pale stool, jaundice (persisting for >2 wk), abdominal distension, hepatomegaly

**Diagnosis**
- conjugated hyperbilirubinemia, abdominal U/S, operative cholangiogram
- HIDA scan (may be bypassed in favour of biopsy if timing of diagnosis is critical)
- liver biopsy

**Treatment**
- surgical drainage procedure
- hepatoporoenterostomy (Kasai procedure; most successful if <8 wk of age)
- two thirds will eventually require liver transplantation
- vitamins A, D, E, and K; diet should be enriched with medium-chain triglycerides to ensure adequate fat ingestion

---

**Necrotizing Enterocolitis**

**Definition**
- intestinal inflammation associated with focal or diffuse ulceration and necrosis
- primarily affecting terminal ileum and colon

**Epidemiology**
- affects 1-5% of preterm newborns admitted to NICU

**Pathophysiology**
- postulated mechanism of bowel ischemia: mucosal damage and enteral feeding → bacterial growth → bowel necrosis/gangrene/perforation

**Risk Factors**
- prematurity (immature defenses)
- asphyxia, shock (poor bowel perfusion)
- hyperosmolar feeds
- enteral feeding with formula (breast milk can be protective)
- sepsis

**Clinical Presentation**
- usually presents at 2-3 wk of age
- distended abdomen
- increased amount of gastric aspirate/vomitus with bile staining
- frank or occult blood in stool
- feeding intolerance
- diminished bowel sounds
- signs of bowel perforation (sepsis, shock, peritonitis, DIC)

**Investigations**
- AXR: pneumonitis intestinalis (intramural air is a hallmark of NEC), free air, fixed loops, ileus, thickened bowel wall, portal venous gas
- CBC, ABG, lactate, blood culture, electrolytes
- high or low WBC, low platelets, hyponatremia, acidosis, hypoxia, hypercapnea

**Treatment**
- NPO (7-10 d), vigorous IV fluid resuscitation, decompression with NG tube, supportive therapy
- TPN
- antibiotics (usually ampicillin, gentamicin ± metronidazole if risk of perforation x 7-10 d)
- serial AXRs detect early perforation (40% mortality in perforated NEC)
- peritoneal drain/surgery if perforation
- surgical resection of necrotic bowel and surgery for complications (e.g. perforation, strictures)

---

**Influence of Enteral Nutrition on Occurrences of Necrotizing Enterocolitis in Very-Low-Birth-Weight Infants**

**Study**: Case control study of very-low-birth-weight (VLBW) infants and occurrences of NEC within 30 d of life.

**Main Outcome**: NEC defined using stage ≥ 2 of modified Bell criteria.

**Results**: 55 infants developed NEC within 30 d of life (5.4%). Those with NEC had higher odds of having been fed breast milk <7 d (OR: 4.02), not having achieved full enteral feeding during the first mo (OR: 3.50), and having had parenteral feeding (OR: 2.70).

**Conclusions**: Occurrence of NEC can be reduced with breast milk feeding beyond 7 d and early full enteral feeding.
**Persistent Pulmonary Hypertension of the Newborn**

**Definition**
- persistence of fetal circulation as a result of persistent elevation of pulmonary vascular resistance
- classified as primary (absence of risk factors) or secondary

**Epidemiology**
- incidence 1.9/1,000 live births

**Clinical Presentation**
- usually presents within 12 h of birth with severe hypoxemia/cyanosis; may have only mild respiratory distress

**Pathophysiology**
- elevated pulmonary pressures cause R → L shunt through PDA, foramen ovale → decreased pulmonary blood flow → hypoxemia → further pulmonary vasoconstriction

**Risk Factors**
- secondary PPHN: asphyxia, MAS, RDS, sepsis, pneumonia, structural abnormalities (e.g., diaphragmatic hernia, pulmonary hypoplasia)
- more common in term or post-term infants

**Investigations**
- measure pre- and post-ductal oxygen levels
- hyperoxia test to exclude CHD
- ECG (RV strain)
- Echo reveals increased pulmonary arterial pressure and a R → L shunt across PDA and patent foramen ovale; also used to rule out other cardiac defects

**Treatment**
- maintain good oxygenation (SaO2 >95%) in at-risk infants
- O2 given early and tapered slowly, minimize stress and metabolic demands, maintain normal blood gases, circulatory support
- mechanical ventilation, high frequency oscillation in a sedated muscle-relaxed infant
- nitric oxide, surfactant
- extracorporeal membrane oxygenation used in some centres when other therapy fails

**Respiratory Distress in the Newborn**

**Clinical Presentation**
- tachypnea: RR >60/min; tachycardia: HR >160/min
- grunting, subcostal/intercostal indrawing, nasal flaring
- duskyenes, central cyanosis
- decreased air entry, crackles on auscultation

**Differential Diagnosis of Respiratory Distress**
- pulmonary: RDS (Respiratory Distress Syndrome), TTN (Transient Tachypnea of the Newborn), MAS (Meconium Aspiration Syndrome), pleural effusion, pneumothorax, congenital lung malformations
- infectious: sepsis, pneumonia
- cardiac: CHD (cyanotic, acyanotic), PPHN
- hematologic: blood loss, polycythemia
- anatomic: TEF, congenital diaphragmatic hernia, mucous or meconium plug, upper airway obstruction (see Otalaryngology, OT41)
- metabolic: hypoglycemia, inborn errors of metabolism
- neurologic: CNS damage (trauma, hemorrhage), drug withdrawal syndromes

**Investigations**
- CXR, ABG (or venous blood gas from umbilical venous line)
- CBC, blood cultures, blood glucose
- ECG if indicated

</tbody>
</table>

**PNEUMONIA**
- see Respirology, P75
- consider in infants with prolonged or premature rupture of membranes, maternal fever, or if mother is GBS positive
- suspect if infant exhibits respiratory distress, temperature instability, or WBC is low, elevated, or left-shifted
- symptoms may be non-specific
- CXR: hazy lung and/or distinct infiltrates (may be difficult to differentiate from RDS)

**Retinopathy of Prematurity**
- see Ophthalmology, OP38
Sepsis in the Neonate

</table>

Signs of Sepsis
- no reliable absolute indicator of occult bacteremia in infants <3 mo, most specific result has been WBC <5
- temperature instability (hypo/hyperthermia)
- respiratory distress, cyanosis, apnea
- tachycardia/bradycardia
- lethargy, irritability
- poor feeding, vomiting, abdominal distension, diarrhea
- hypotonia, seizures, lethargy
- jaundice, hepatomegaly, petechiae, purpura

Skin Conditions of the Neonate

</tbody>
</table>

Fluids and Electrolytes

Approach to Infant/Child with Dehydration

Etiology
- decreased intake: poor oral intake during acute illness, breastfeeding difficulties, eating disorders
- increased losses: common sites include GI tract (diarrhea, vomiting, bleeding), skin/mucous membranes (fever, burns, hemorrhage, stomatitis), urine (osmotic diuresis [e.g. hyperglycemia, DKA], diuretic therapy, DI, post-obstructive/post ATN recovery diuresis), and respiratory tract (tachypnea, bronchiolitis, pneumonia)
Management

- If suspect dehydration based on history (acute illness, decreased number of wet diapers, lethargy, changes in mental status, increased thirst, etc.), you must:

1) Determine degree of extracellular volume contraction

| Table 31. Assessment of Degree of Extracellular Volume Contraction Based on Physical Exam |
|----------------------------------------|-----------------|-----------------|-----------------|
|                                       | Mild            | Moderate        | Severe          |
| Age                                   | <2 yr           | >2 yr           |                  |
| Pulse                                 | Normal, full    | Rapid           | Rapid, weak     |
| Blood Pressure                         | Normal          | Low to normal   | Decreased in shock (very late finding in pediatrics and very dangerous) |
| Urine Output                          | Decreased       | Markedly decreased | Anuria          |
| Oral Mucosa                           | Slightly dry    | Dry             | Parched         |
| Anterior Fontanelle                   | Normal          | Sunken          | Markedly sunken |
| Eyes                                   | Normal          | Sunken          | Markedly sunken |
| Skin Turgor                           | Normal          | Decreased       | Tenting         |
| Capillary Refill                      | Normal (< 3 s)  | Normal to increased | Increased (> 3 s) |

* Note that percentages refer to percent loss of pre-illness body weight

2) Determine the likely electrolyte disturbance

- Dependent on etiology of dehydration and type of fluid loss (isotonic vs. hypertonic vs. hypotonic)

<table>
<thead>
<tr>
<th>Table 32. Electrolyte Content of Various Bodily Fluids</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bodily Fluid</td>
</tr>
<tr>
<td>Saliva</td>
</tr>
<tr>
<td>Gastric Juice</td>
</tr>
<tr>
<td>Pancreatic Juice</td>
</tr>
<tr>
<td>Bile</td>
</tr>
<tr>
<td>Small Bowel</td>
</tr>
<tr>
<td>Large Bowel</td>
</tr>
<tr>
<td>Sweat</td>
</tr>
</tbody>
</table>

- For moderate and severe dehydration, initial investigations should include urinalysis and blood work examining electrolyte (Na⁺, K⁺, Cl⁻), glucose, and acid-base (blood pH, pCO₂, HCO₃⁻ disturbances) and impaired renal function (creatinine, BUN)

3) Determine if the child requires PO or IV rehydration

- Dehydrated child must receive adequate fluid management, including replacement of ongoing losses and maintenance fluids

- ORT indication: mild to moderate dehydration caused by diarrhea
  - Advantages: ↓ cost, no IV needed, ↓ incidence of iatrogenic hyper/hyponatremia, parental involvement in therapy

- IV rehydration indications: indications for IV rehydration therapy: severe dehydration requiring close monitoring and frequent assessment of electrolytes, inability to tolerate ORT (e.g. vomiting, alteration in mental status, ileus, monosaccharide malabsorption, etc.), inability to provide ORT, failure of ORT in providing adequate rehydration (e.g. persistent diarrhea or vomiting)

4) Return the child to a normal volume and electrolyte status by replacing current deficits and ongoing losses

![Figure 6. Algorithm for deficit replacement and replacement of ongoing losses in the dehydrated child](image-url)
5) Provide the appropriate fluid and electrolyte maintenance daily requirements

<table>
<thead>
<tr>
<th>Body Weight</th>
<th>100:50:20 Rule (24 h maintenance fluids)</th>
<th>4:2:1 Rule (hourly rate of maintenance fluids)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-10 kg</td>
<td>100 cc/kg/d</td>
<td>4 cc/kg/h</td>
</tr>
<tr>
<td>11-20 kg</td>
<td>1000 cc + 50 cc/kg/d for every kg &gt; 10 kg</td>
<td>40 cc + 2 cc/kg/h for every kg &gt; 10 kg</td>
</tr>
<tr>
<td>&gt;20 kg</td>
<td>1500 cc + 20 cc/kg/d for every kg &gt; 20 kg</td>
<td>60 cc + 1 cc/kg/h for every kg &gt; 20 kg</td>
</tr>
</tbody>
</table>

- in children, all maintenance fluids should have a dextrose component due to their higher risk of hypoglycemia, especially if they are NPO
- common IV fluid combinations used in pediatrics
  - newborn: D10W
  - first month of life: D5W/0.45 2 NS + KCl 20 mEq/L (only add KCl if voiding well)
  - children: D5W/NS + KCl 20 mEq/L or D5W/0.45 NS + KCl 20 mEq/L; NS bolus for dehydration
- most important thing to remember when correcting Na aberration due to fluid deficits
  - risk of cerebral edema with rapid rehydration with hypotonic or isotonic solutions (i.e. NS), therefore replace fluid slowly with close monitoring; aim to adjust (increase or decrease) plasma [Na+] by no more than 12 mmol/L/d
  - management depends on etiology, severity of symptoms, and timing (acute vs. chronic)

6) Continue to monitor fluid and electrolyte status
- accurate monitoring of daily fluid intake (PO and IV) and ongoing losses (urine output, diarrhea, emesis, drains)
- if child receiving >50% of maintenance fluids through IV, serum electrolyte values should be monitored daily and therapy adjusted accordingly
- avoid iatrogenic hyper/hyponatremia, keep the possibility of SIADH in mind

### Nephrology

<td>UTI, vulvovaginitis</td>
</tr>
</tbody>
</table>

### Hemolytic Uremic Syndrome

**Definition**
- simultaneous occurrence of the triad of 1) non-immune microangiopathic hemolytic anemia, 2) thrombocytopenia, and 3) acute renal injury

**Epidemiology**
- annual incidence of 1-2 per 100,000 in Canada
- most common cause of acute renal failure in children

**Etiology**
- diarrhea positive HUS: 90% of pediatric HUS from *E. coli* O157:H7, shiga toxin, or verotoxin
- diarrhea negative HUS: other bacteria, viruses, drugs, familial/genetic
Pathophysiology
- toxin binds, invades, and destroys colonic epithelial cells, causing bloody diarrhea
- toxin enters the systemic circulation, attaches to, and injures endothelial cells (especially in kidney), causing a release of endothelial products (e.g. von Willebrand factor, platelet aggregating factor)
- platelet/fibrin thrombi form in multiple organ systems (e.g. kidney, pancreas, brain, etc.) resulting in thrombocytopenia
- RBCs are forced through occluded vessels, resulting in fragmented RBCs (schistocytes) that are removed by the reticuloendothelial system (hemolytic anemia)

History and Physical Exam
- history: initial presentation of abdominal pain and diarrhea, followed by bloody diarrhea; within 5-7 d begins to show signs of anemia, thrombocytopenia, and renal insufficiency
- physical exam: pallor, jaundice (hemolysis), edema, petechiae, HTN

Investigations
- CBC (anemia, thrombocytopenia), blood smear (schistocytes), electrolytes, renal function, urinalysis (microscopic hematuria), stool cultures, and verotoxin/shigella toxin assay

Management
- mainly supportive: nutrition, hydration, ventilation (if necessary), blood transfusion for symptomatic anemia
- monitor electrolytes and renal function: dialysis if electrolyte abnormality (hyperkalemia) cannot be corrected, fluid overload, or uremia
- steroids are not helpful
- antibiotics are contraindicated because death of bacteria leads to increased toxin release and worse clinical course

Prognosis
- <5% mortality, 5-25% long-term renal damage (HTN, proteinuria, decreased renal function)

Nephritic Syndrome

Definition
- acute or chronic syndrome affecting the kidney, characterized by glomerular injury and inflammation, and defined by hematuria (>5 RBCs per high-powered microscope field) and the presence of dysmorphic RBCs and RBC casts on urinalysis
- often accompanied by at least one of proteinuria (<50 mg/kg/d), edema, HTN, azotemia, and oliguria

Epidemiology
- highest incidence in children aged 5-15 yr old

Etiology
- humoral immune response to a variety of etiologic agents → immunoglobulin deposition → complement activation, leukocyte recruitment, release of growth factors/cytokines → glomerular inflammation and injury → porous podocytes → hematuria + RBC casts ± proteinuria
- HTN secondary to fluid retention and increased renin secretion by ischemic kidneys

Table 35. Major Causes of Nephritic Syndrome

<table>
<thead>
<tr>
<th></th>
<th>Decreased C3</th>
<th>Normal C3</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Primary</strong> (idiopathic)</td>
<td>Post-infectious GN (most common cause of acute GN in pediatrics)</td>
<td>IgA nephropathy</td>
</tr>
<tr>
<td></td>

<td>SLE</td>
<td>HSP (very common)</td>
</tr>
<tr>
<td></td>
<td>Bacterial endocarditis</td>
<td>Polyaartitis nodosa</td>
</tr>
<tr>
<td></td>
<td>Abscess or shunt nephritis</td>
<td>Granulomatosis with polyangiitis</td>
</tr>
<tr>
<td></td>
<td>Cryoglobulinemia</td>
<td>Goodpasture’s syndrome</td>
</tr>
</tbody>
</table>

History and Physical Exam
- often asymptomatic; some overlap in clinical findings for nephritic and nephrotic syndrome
- gross hematuria, mild-moderate edema, oliguria, HTN
- signs and symptoms suggestive of underlying systemic causes (e.g. fever, arthralgias, rash, dyspnea, pulmonary hemorrhage)

Investigations
- urine
  - dipstick (hematuria, 0 to 2+ proteinuria) and microscopy (>5 RBCs per high-powered microscope field, acanthocytes, RBC casts)
  - first morning urine protein/creatinine ratio (<200 mg/mmol)
• blood work
  • impaired renal function (↑ Cr and BUN) resulting in ↓ pH and electrolyte abnormalities (hyperkalemia, hyperphosphatemia, hypocalcemia)
  • mild anemia on CBC (secondary to hematuria)
  • hyponatremia (secondary to proteinuria)
  • appropriate investigations to determine etiology: C3/C4 levels, serologic testing for recent streptococcal infection (ASOT, anti-hyaluronidase, anti-streptokinase, anti-NAD, anti-DNAse B), ANA, anti-DNA antibodies, ANCA, serum IgA levels, anti-GBM antibodies
  • renal biopsy should be considered only in the presence of acute renal failure, no evidence of streptococcal infection, normal C3/C4

Management
• treat underlying cause
• symptomatic
  • renal insufficiency: supportive (dialysis if necessary), proper hydration
  • HTN: salt and fluid restriction (but not at expense of renal function) ACEI or ARBs for chronic persistent HTN (not acute cases because ACEI or ARBs may decrease GFR further)
  • edema: salt and fluid restriction, possibly diuretics (avoid if significant intravascular depletion)
  • corticosteroids if indicated: IgA nephropathy, lupus nephritis, etc.

Prognosis
• dependent on underlying etiology
• complications include HTN, heart failure, pulmonary edema, chronic kidney injury (requiring renal transplant)

Nephrotic Syndrome

Definition
• clinical syndrome affecting the kidney, characterized by significant proteinuria, peripheral edema, hypoalbuminemia, and hyperlipidemia

Epidemiology
• highest incidence in children 2-6 yr old, M>F

Etiology
• primary (idiopathic): nephrotic syndrome in the absence of systemic disease (most common cause in pediatrics)
  • glomerular inflammation ABSENT on renal biopsy: MCD (85%), focal segmental glomerular sclerosis
  • glomerular inflammation PRESENT on renal biopsy: membranoproliferative GN, IgA nephropathy
• secondary: nephrotic syndrome associated with systemic disease or due to another process causing glomerular injury (<10% in pediatrics)
  • autoimmune: SLE, DM, rheumatoid arthritis
  • genetic: sickle cell disease, Alport syndrome
  • infections: hepatitis B/C, post-streptococcal, infective endocarditis, HUS, HIV
  • malignancies: leukemia, lymphoma
  • medications: captopril, penicillamine, NSAIDs, antiepileptics
  • vasculitides: HSP, granulomatosis with polyangiitis
• congenital: congenital nephropathy of the Finnish type, Denys-Drash syndrome, etc.

History and Physical Exam
• non-specific symptoms such as irritability, malaise, fatigue, anorexia, or diarrhea
  • edema
    • often first sign: detectable when fluid retention exceeds 3-5% of body weight
    • starts periocular and often pretibial → edematous areas are white, soft, and pitting
    • gravity dependent: periocular edema ↓ and pretibial edema ↑ over the day
    • anasarca may develop (i.e. marked periocular and peripheral edema, ascites, pleural effusions, scrotal/labial edema)
• decrease in effective circulating volume (e.g. tachycardia, HTN, oliguria, etc.)
• foamy urine is a possible sign of proteinuria
Investigations

- urine
  - urine dipstick (3 to 4+ proteinuria, microscopic hematuria) and microscopy (oval fat bodies, hyaline casts)
  - first morning urine protein/creatinine ratio (>200 mg/mmol)
- blood work
  - diagnostic: hypoalbuminemia (<25 g/L), hyperlipidemia/hypercholesterolemia (total cholesterol >5 mmol/L)
  - secondary: electrolytes (hypocalcemia, hyperkalemia, hyponatremia), renal function (↑ BUN and Cr), coagulation profile (4 PTT)
  - appropriate investigations to rule out secondary causes: CBC, blood smear, C3/C4, ANA, hepatitis B/C titres, ASOT, HIV serology, etc.
- consider renal biopsy if: HTN, gross hematuria, renal function, low serum C3/C4, no response to steroids after 4 wk of therapy, frequent relapses (>2 in 6 mo), presentation before first yr of life (high likelihood of congenital nephrotic syndrome), presentation ≥12 yr (rule out more serious renal pathology than MCD)

Management

- MCD: oral prednisone 2 mg/kg/d (or equivalent) for up to 12 wk → varicella status should be known before starting
- consider cytotoxic agents, immunomodulators, or high-dose pulse corticosteroid if steroid resistant
- symptomatic
  - edema: salt and fluid restriction, possibly diuretic (avoid if significant intravascular depletion); furosemide + albumin for anasarca
  - hyperlipidemia: generally resolves with remission; limit dietary fat intake; consider statin therapy if persistently nephrotic
  - hypoalbuminemia: IV albumin and furosemide not routinely given; consider if refractory edema
  - abnormal BP: control BP; fluid resuscitation if severe intravascular depletion; ACEI or ARBs for persistent HTN
  - diet: no added salt; monitor caloric intake and supplement with Ca2+ and Vit D if on corticosteroids
  - daily weights and BP to assess therapeutic progress
  - secondary infections: treat with appropriate antimicrobials; antibiotic prophylaxis not recommended; pneumococcal vaccine at diagnosis and varicella vaccine after remission; varicella Ig + acyclovir if exposed while on corticosteroids
  - secondary hypercoagulability: mobilize, avoid hemoconcentration due to hypovolemia, prompt sepsis treatment; heparin if thrombi occur

Prognosis

- generally good: 80% of children responsive to corticosteroids
- up to 2/3 experience relapse, often multiple times; sustained remission with normal kidney function usually by adolescence
- complications: ↑ risk of infections (spontaneous peritonitis, cellulitis, sepsis); hypercoagulability due to decreased intravascular volume and antithrombin III depletion (PE, renal vein thrombosis); intravascular volume depletion, leading to hypotension, shock, renal failure; side effects of drugs

Hypertension in Childhood

Definition

- HTN: sBP and/or dBP ≥95th percentile for sex, age, and height on ≥3 occasions
- pre-HTN: sBP and/or dBP ≥90th percentile but <95th percentile OR BP ≥120/80 irrespective of age, gender, and height

Table 36. 95th Percentile Blood Pressures (mmHg)

<td>136/87</td>
<td>138/87</td>
</tr>
</tbody>
</table>

Epidemiology

- prevalence: 3-5% for HTN, 7-10% for pre-HTN; M>F
- increasing prevalence of pre-HTN over the last 25+ yr
Etiology
- primary HTN
  - diagnosis of exclusion
  - most common in older children (≥10 yr), especially if positive family history, overweight, and only mild HTN
  - responsible for ~90% of cases of HTN in adolescents, rarely in young children
- secondary HTN
  - identifiable cause of HTN (most likely etiology depends on age)
  - responsible for majority of childhood HTN
  - always consider white coat HTN for all ages

Table 37. Etiology of Secondary HTN by Age Group

</tr>
</tbody>
</table>

*Note: may include hyperthyroidism, hyperparathyroidism, Gushing’s syndrome, primary hyperaldosteronism/Carr’s syndrome, pheochromocytoma

Risk Factors
- primary HTN: male gender, positive family history, obesity, obstructive sleep apnea, African American, prematurity/LBW
- secondary HTN: history of renal disease, abdominal trauma, family history of autoimmune diseases, umbilical artery catheterization

History
- often asymptomatic, but can include FTT, fatigue, epistaxis
- symptoms of hypertensive emergency
  - neurologic: headache, seizures, focal complaints, change in mental status, visual disturbances
  - cardiovascular: symptoms of MI or heart failure (chest pain, palpitations, cough, SOB)
- symptoms of secondary HTN: guided by etiology; ask about medications and recreational drugs (current and past)

Physical Exam
- BP measurement (make sure correct cuff size is used), plot on growth chart, BMI
- look for signs of hypertensive emergency (e.g. full neurologic exam, ophthalmoscopy, precordial exam, peripheral pulses, perfusion status)
- look for signs of secondary HTN

Investigations
- laboratory
  - urine dipstick for hematuria and/or proteinuria (renal disease), urine catecholamines (pheochromocytoma, neuroblastoma)
  - blood work: renal function tests (electrolytes, Cr, BUN), consider renin and aldosterone levels (RAS, Conn’s syndrome, Wilms’ tumour)
  - other specific hormones if indicated on history and physical
  - imaging: Echo (coarctation, heart function), abdominal U/S (RAS, abdominal mass), renal radionuclide imaging (renal scarring)

Management
- treat underlying cause
- non-pharmacologic: modify concurrent cardiovascular risk factors (weight reduction, exercise, salt restriction, smoking cessation)
- pharmacologic: gradual lowering of BP using thiazide diuretics; no antihypertensives have been formally studied in children; if hypertensive emergencies use hydralazine, labetalol, sodium nitroprusside
- management of end-organ damage (e.g. retinopathy, LVH)
- consider referral to specialist

Prognosis
- end-organ damage (similar to adults) including LVH, CHF cerebrovascular insults, renal disease, retinopathy
Neurology

Seizure Disorders

• see Neurology N18

Differential Diagnosis of Seizures in Children

• benign febrile seizure
• CNS: infection, tumour, HIE, trauma, hemorrhage
• metabolic: hypoglycemia, hypocalcemia, hyponatremia
• idiopathic epilepsy and epileptic syndromes
• others: neurocutaneous syndromes, AVM, drug ingestions/withdrawal
• seizure mimics

Investigations

• lab tests: CBC, electrolytes, calcium, magnesium, glucose
• toxicology screen if indicated
• EEG
• CT/MRI, if indicated (focal neurological deficit or has not returned to baseline several hours after seizure)
• consider LP if first-time non-febrile seizure (not indicated for determining recurrence risk of benign febrile seizures or to determine seizure type or epileptic syndrome)

CHILDHOOD EPILEPSY SYNDROMES

Infantile Spasms

• brief, repeated symmetric contractions of neck, trunk, extremities (flexion and extension) lasting 10-30 s
• occur in clusters; often associated with developmental delay; onset 4-8 mo
• 20% unknown etiology (usually good response to treatment); 80% due to metabolic or developmental abnormalities, encephalopathies, or are associated with neurocutaneous syndromes (usually poor response to treatment)
• can develop into West syndrome (infantile spasms, psychomotor developmental arrest, and hypsarrhythmia) or Lennox-Gastaut (see below)
• typical EEG hypsarrhythmia (high voltage slow waves, spikes and polyspikes, background disorganization)
• management: ACTH, vigabatrin, benzodiazepines

Lennox-Gastaut

• characterized by triad of 1) multiple seizure types, 2) diffuse cognitive dysfunction, and 3) slow generalized spike and slow wave EEG
• onset commonly 3-5 yr of age
• seen with underlying encephalopathy and brain malformations
• management: valproic acid, benzodiazepines, and ketogenic diet; however, response often poor

Juvenile Myoclonic Epilepsy (Janz Syndrome)

• myoclonus particularly in morning; frequently presents as generalized tonic-clonic seizures
• adolescent onset (12-16 yr of age); autosomal dominant with variable penetrance
• typical EEG: 3.5-6 Hz irregular spike and wave, increased with photic stimulation
• management: lifelong treatment (valproic acid); excellent prognosis

Childhood Absence Epilepsy

• multiple daily absence seizures lasting <30 s without post-ictal state that may resolve spontaneously or become generalized in adolescence
• peak age of onset 6-7 yr, F>M, strong genetic predisposition
• typical EEG: 3 Hz spike and wave
• management: valproic acid or ethosuximide

Benign Focal Epilepsy of Childhood with Rolandic/Centrotemporal Spikes

• focal motor seizures involving tongue, mouth, face, upper extremity usually occurring in sleep-wake transition states; remains conscious, but aphasic post-ictally
• onset peaks at 5-10 yr of age; 16% of all non-febrile seizures; remits spontaneously in adolescence without sequelae
• typical EEG: repetitive spikes in centrotemporal area with normal background
• management: frequent seizures controlled by carbamazepine, no medication if infrequent seizures
General Approach to Treatment
- education for patient and parents including education and precautions in daily life (e.g. buddy system, showers instead of baths)
- medication
  - initiate: treatment with drug appropriate to seizure type; often if >2 unprovoked afebrile seizures within 6-12 mo
  - optimize: start with one drug and increase dosage until seizures controlled
  - if no effect, switch over to another before adding a second antiepileptic drug
- ketogenic diet (high fat diet): used in patients who do not respond to polytherapy or who do not wish to take medication (valproic acid contraindicated in conjunction with ketogenic diet because may increase hepatotoxicity)
- legal obligation to report to Ministry of Transportation if patient wishes to drive

Generalized and Partial Seizures
- see Neurology, N44

Febrile Seizures

Epidemiology
- most common cause of seizure in children (3-5% of children)
- M>F, age 6 mo-6 yr

Clinical Presentation
- often with associated illness or fever and family history
- no evidence of CNS infection/inflammation before or after seizure; no history of non-febrile seizures

Table 38. Comparison of Typical and Atypical Febrile Seizures

<table>
<thead>
<tr>

<td>Recurrent seizures (&gt; 1 in 24 h period)</td>
</tr>
<tr>
<td>No neurological impairment or developmental delay before or after seizure</td>
<td>Previous neurological impairment or neurological deficit after seizure</td>
</tr>
</tbody>
</table>

Workup
- history: determine focus of fever, description of seizure, medications, trauma history, development, family history
- physical exam: LOC, signs of meningitis, neurological exam, head circumference, focus of infection
- septic workup including LP if suspecting meningitis (strongly consider if child <12 mo; consider if child is 12-18 mo; only if meningeal signs present if child >18 mo)
- if typical febrile seizure, investigations only for determining focus of fever
- EEG/CT/MRI brain not warranted unless atypical febrile seizure or abnormal neurologic findings

Management
- counsel and reassure patient and parents
  - febrile seizures do not cause brain damage
  - very small risk of developing epilepsy: 9% in child with multiple risk factors; 2% in child with typical febrile seizures compared to 1% in general population
  - 33% chance of recurrence (mostly within 1 yr of first seizure and in children <1 yr old)
  - antipyretics and fluids for comfort (though neither prevent seizure)
  - prophylaxis with antiepileptic drugs not recommended
  - if high risk for recurrent or prolonged seizures, have rectal or sublingual lorazepam at home
- treat underlying cause of fever

Recurrent Headache
- see Neurology, N44

Differential Diagnosis
- primary headache: tension, migraine, cluster
- secondary headache: see Neurology, N44

General Assessment
- if unremarkable history and neurological and general physical exam is negative, most likely diagnosis is migraine or tension headache
- CT or MRI if history or physical reveals red flags
- inquire about level of disability, academic performance, after-school activities
Hypotonia

- decreased resistance to passive movements – “floppy baby”

Differential Diagnosis

central: chromosomal (DS, Prader-Willi, Fragile X syndrome), metabolic (hypoglycemia, kernicterus), perinatal problems (asphyxia, ICH), endocrine (hypothyroidism, hypopituitarism), systemic illness (TORCH infection, sepsis, dehydration), CNS malformations, dysmorphic syndromes

peripheral: motor neuron (spinal muscular atrophy, polio), peripheral nerve (Charcot-Marie-Tooth syndrome) neuromuscular junction (myasthenia gravis), muscle fibre (mitochondrial myopathy, muscular dystrophy, myotonic dystrophy)

History and Physical Exam

- proper assessment of tone requires accurate determination of GA
- differentiate between UMN and LMN lesion: spontaneous posture (spontaneous movement, movement against gravity, frog-leg position); muscle weakness; joint mobility (hyperextensibility); muscle bulk; presence of fasciculations
- postural maneuvers
  - traction response: pull to sit, look for flexion of arms to counteract traction and head lag
  - axillary suspension: suspend infant by holding at axilla and lifting; hypotonic babies will slip through grasp because of low shoulder girdle tone
  - ventral suspension: infant is prone and supported under the abdomen by one hand; infant should be able to hold up extremities; inverted “U” posturing demonstrates hypotonia
- dysmorphic features, cognitive ability, reflexes, strength

Investigations

- rule out systemic disorders (e.g. electrolytes, ABG, blood glucose, CK, and serum/urine investigations for multiple etiologies including mitochondrial causes)
- neuroimaging: MRI/MRA when indicated
- EMG, muscle biopsy/NCS
- chromosome analysis, genetic testing, metabolic testing, neuromuscular testing

Treatment

- depends on etiology: some treatments available for specific diagnosis
- counsel parents on prognosis and genetic implications
- refer patients for specialized care, refer for rehabilitation, OT, PT; assess feeding ability

Cerebral Palsy

Definition

- a symptom complex, not a disease
- non-progressive central motor impairment syndrome due to insult to or anomaly of the immature CNS
- incidence: 1.5–2.5/1,000 live births (industrialized nations)
- life expectancy is dependent on the degree of mobility and intellectual impairment, not on severity of CNS lesion

Etiology

- often obscure, no definite etiology identified in 1/3 of cases
- 10% related to intrapartum asphyxia; 10% due to postnatal insult (infections, asphyxia, prematurity with IVH and trauma)
- association with LBW babies

Clinical Presentation

- general signs: delay in motor milestones, developmental delay, learning disabilities, visual/hearing impairment, seizures, microcephaly, uncoordinated swallow (aspiration)

Table 39. Types of Cerebral Palsy

Investigations
• may include metabolic screen, chromosome studies, serology, neuroimaging (MRI), EMG, EEG (if seizures), ophthalmology assessment, audiology assessment

Treatment
• maximize potential through multidisciplinary services such as primary care physician, OT, PT, SLP, school supports, etc.
• orthopedic management (e.g. dislocations, contractures, rhizotomy)
• management of symptoms: spasticity (baclofen, Botulinum toxin), constipation (stool softeners)

Neurocutaneous Syndromes
• characterized by tendency to form tumours of the CNS, PNS, viscera, and skin

NEUROFIBROMATOSIS TYPE I
• autosomal dominant but 50% are the result of new mutations
• also known as von Recklinghausen disease
• incidence 1:3,000, mutation in NF1 gene on 17q11.2 (codes for neurofibromin protein)
• learning disorders, abnormal speech development, and seizures are common
• diagnosis of NF-1 requires 2 or more of:
  ■ ≥6 café-au-lait spots (>5 mm if prepubertal, >1 5 cm if postpubertal)
  ■ ≥2 neurofibromas of any type or one plexiform neurofibroma
  ■ ≥2 Lisch nodules (hamartomas of the iris)
  ■ optic glioma
  ■ freckling in the axillary or inguinal region
  ■ a distinctive bony lesion (e.g. sphenoid dysplasia, cortical thinning of long bones)
  ■ a first degree relative with confirmed NF-1

NEUROFIBROMATOSIS TYPE II
• autosomal dominant
• incidence 1:33,000
• characterized by predisposition to form intracranial, spinal tumours
• diagnosed when bilateral vestibular schwannomas are found, or a first degree relative with NF-2 and either unilateral vestibular schwannoma, or any two of the following: meningioma, glioma, schwannoma neurofibroma, posterior subcapsular lenticular opacities.
• treatment consists of monitoring for tumour development and surgery

Respirology
Approach to Dyspnea
• determine if patient is sick or not sick; ABCs
• history: onset, previous episodes, precipitating events, associated symptoms, past medical/family history of respiratory disease
• physical exam: vitals, SpO2, evidence of cyanosis, respiratory, cardiovascular
• investigations: CBC and differential, electrolytes, BUN, Cr, NP swab, ABG, CXR, ECG (based on clinical findings)

Figure 17. Approach to dyspnea in childhood
Upper Respiratory Tract Diseases

- see Otolaryngology, OT40
- diseases above the thoracic inlet characterized by inspiratory stridor, hoarseness, and suprasternal retractions
- differential diagnosis of stridor: croup, bacterial tracheitis, epiglottitis, foreign body aspiration, subglottic stenosis (congenital or iatrogenic), laryngomalacia/tracheomalacia (collapse of airway cartilage on inspiration)

</tbody>
</table>

Lower Respiratory Tract Diseases

- obstruction of airways below thoracic inlet, produces more expiratory sounds
- classic symptom: wheezing

Differential Diagnosis of Wheezing

- common: asthma (recurrent wheezing episodes, identifiable triggers, typically over 6 yr), bronchiolitis (first episode of wheezing, usually under 1 yr), recurrent aspiration (often neurological impairment), pneumonia (fever, cough, malaise)
- uncommon: foreign body (acute unilateral wheezing and coughing), CF (prolonged wheezing, unresponsive to therapy), bronchopulmonary dysplasia (often develops after prolonged ventilation in the newborn)
- rare: CHF, mediastinal mass, bronchiolitis obliterans, tracheobronchial anomalies

Pneumonia

Etiology

- inflammation of pulmonary tissue, associated with consolidation of alveolar spaces

Clinical Presentation

- incidence is greatest in first year of life with viral causes being most common in children <5 yr
- fever, cough, tachypnea
- CXR: diffuse, streaky infiltrates bilaterally
- bacterial causes may present with cough, fever, chills, dyspnea, more dramatic CXR changes (e.g. lobar consolidation, pleural effusion)

Management

- supportive therapy: hydration, antipyretics, humidified O₂

Bronchiolitis

Definition
LRTI, usually in children <2 yr, that has wheezing and signs of respiratory distress

Epidemiology
- the most common LRTI in infants, affects 50% of children in first 2 yr of life; peak incidence at 6 mo, winter or early spring
- increased incidence of asthma in later life

Etiology
- RSV (>50%), parainfluenza, influenza, rhinovirus, adenovirus, M. pneumoniae (rare)

Clinical Presentation
- prodrome of URTI with cough and/or rhinorrhea, possible fever
- feeding difficulties, irritability
- wheezing, crackles, respiratory distress, tachypnea, tachycardia, retractions, poor air entry; symptoms often peak at 3-4 d

Investigations
- CXR (only in severe disease, poor response to therapy, chronic episode): air trapping, peribronchial thickening, atelectasis, increased linear markings
- NP swab: direct detection of viral antigen (immunofluorescence)
- WBC can be normal

Treatment
- self-limiting disease with peak symptoms usually lasting 2-3 wk
- mild to moderate distress
  - supportive: PO or IV hydration, antipyretics for fever, regular or humidified high flow O2
  - severe distress
    - as above ± intubation and ventilation as needed
    - consider rebetol (Ribavirin®) in high risk groups: bronchopulmonary dysplasia, CHD, congenital lung disease, immunodeficient
    - monthly RSV-Ig or palivizumab (monoclonal antibody against the F-glycoprotein of RSV) is protective against severe disease in high risk groups; case fatality rate <1%
- antibiotics have no therapeutic value unless there is secondary bacterial pneumonia
- indications for hospitalization
  - hypoxia: O2 saturation <92% on initial presentation
  - persistent resting tachypnea >60/min and retractions after several salbutamol masks
  - past history of chronic lung disease, hemodynamically significant cardiac disease, neuromuscular problem, immunocompromised
  - young infants <6 mo old (unless extremely mild)
  - significant feeding problems
  - social problem (e.g. inadequate care at home)

Children with bronchiolitis do not respond to ipratropium bromide (Atrovent®) or steroids
Asthma

Definition
- inflammatory disorder of the airways characterized by recurrent episodes of reversible small airway obstruction, resulting from airway hyperresponsiveness to endogenous and exogenous stimuli
- very common, presents most often in early childhood
- associated with other atopic diseases such as allergic rhinitis or atopic dermatitis

Clinical Presentation
- episodic bouts of wheezing, dyspnea, tachypnea, cough (usually at night/early morning, with activity, or cold exposure)
- physical exam may reveal hyper-resonant chest, prolonged expiration, wheeze

Triggers
- URTI (viral or Mycoplasma), weather (cold exposure, humidity changes), allergens (pets), irritants (cigarette smoke) exercise, emotional stress, drugs (ASA, β-blockers)

Classification
- mild: occasional attacks of wheezing or coughing (<2/wk); symptoms respond quickly to inhaled bronchodilators; never needs systemic corticosteroids
- moderate: more frequent episodes with symptoms persisting and chronic cough; decreased exercise tolerance; sometimes needs systemic corticosteroids
- severe: daily and nocturnal symptoms; frequent ED visits and hospitalizations; usually needs systemic corticosteroids

Management
- acute
  - O₂ (keep O₂ saturation >94%) and fluids if dehydrated
  - β₂-agonists: salbutamol (Ventolin®) MDI + spacer (nebulized or IV in very severe episodes with impending respiratory failure), 3 puffs (<20 kg) or 10 puffs q20min for first h (>20 kg)
  - ipratropium bromide (Atrovent®) if severe: MDI + spacer, 3 puffs (<20 kg) or 6 puffs (>20 kg) q20min with salbutamol, or add to first 3 salbutamol masks (0.25 mg if <20 kg, 0.5mg if >20 kg)
  - steroids: prednisone (1-2 mg/kg x 5 d) or dexamethasone 0.5 mg/kg/d x 5 d or 0.6 mg/kg/d x 2 d; in severe disease, use IV steroids
  - continue to observe; can discharge patient if asymptomatic for 2-4 h after last dose
- chronic
  - education, emotional support, avoid allergens or irritants, develop an “action plan”
  - exercise program (e.g. swimming)
  - monitor respiratory function with peak flow meter (improves self-awareness of status)
  - PFTs for children >6 yr
  - reliever therapy: short acting β₂-agonists (e.g. salbutamol)
  - controller therapy (first line therapy for all children): low dose daily inhaled corticosteroids
  - second line therapy for children <12 yr: moderate dose of daily inhaled corticosteroids
  - second line therapy for children >12 yr: leukotriene receptor antagonist OR long acting β₂-agonist in conjunction with low dose inhaled corticosteroids; leukotriene receptor antagonist monotherapy may be considered an alternative second line therapy
  - severe asthma unresponsive to first and second line treatments: injection immunotherapy
  - aerochamber for children using daily inhaled corticosteroids
  - indications for hospitalization
    - ongoing need for supplemental O₂
    - persistently increased work of breathing
    - β₂-agonists are needed more often than q4h after 4 8 h of conventional treatment
    - patient deteriorates while on systemic steroids

Cystic Fibrosis

- see Respirology, R12

Etiology
- 1: per 3,000 live births, mostly Caucasians
- autosomal recessive, CFTR gene found on chromosome 7 (ΔF508 mutation in 70%, but >1,600 different mutations identified) resulting in a dysfunctional chloride channel on the apical membrane of cells
- leads to relative dehydration of airway secretions, resulting in impaired mucociliary transport and airway obstruction
**Clinical Presentation**
- neonatal: meconium ileus, prolonged jaundice, antenatal bowel perforation
- infancy: pancreatic insufficiency with steatorrhea and FTT (despite voracious appetite), anemia, hypoproteinemia, hyponatremia
- childhood: heat intolerance, wheezing or chronic cough, recurrent chest infections (S. aureus, P. aeruginosa, H. influenzae), hemoptysis, nasal polyps, distal intestinal obstruction syndrome, rectal prolapse, clubbing of fingers
- older patients: COPD, infertility (males), decreased fertility (female)

**Investigations**
- sweat chloride test x 2 (>60 mEq/L)
  - false positive tests: malnutrition, atopic dermatitis, hypothyroidism, hypoparathyroidism, GSD, adrenal insufficiency, G6PD, Klinefelter syndrome, technical issues, autonomic dysfunction, familial cholestasis syndrome
  - false negative tests: technical problem with test, malnutrition, skin edema, mineralocorticoids

**Management**
- nutritional counselling: high calorie diet, pancreatic enzyme replacements, fat soluble vitamin supplements
- management of chest disease: physiotherapy, postural drainage, exercise, bronchodilators, aerosolized DNAse and inhaled hypertonic saline, antibiotics (e.g. cefalosporin, cloxacillin, ciprofloxacin, inhaled tobramycin depending on sputum C&S), lung transplantation
- genetic counselling

**Complications**
- respiratory failure, pneumothorax (poor prognostic sign), cor pulmonale (late), pancreatic fibrosis with DM, gallstones, cirrhosis with portal HTN, infertility (male)
- early death (current median survival in Canada is 46.6 yr)

- must rule out infection, malignancy, and acute orthopedic conditions
History
- demographics (age, gender)
- pattern of onset and progression of symptoms (including acuity and chronicity)
- morning stiffness, limp/weight-bearing status, night pain
- joint involvement (type, distribution) ± spine (axial) involvement
- extra-articular manifestations and systemic symptoms
- functional status – activities of daily living
  family history (arthritis, IBD, psoriasis, spondyloarthropathies, uveitis, bleeding disorders, sickle cell anemia)
- past medical illness, intercurrent infection, travel, sick contact history, joint injury

Physical Exam
- growth parameters
- screening examination (pediatric gait, arms, legs, spine exam)
- joint exam: inspection/palpation (swelling, erythema, warmth, tenderness, deformity), ROM
- adjacent structures (bone, tendon, muscle, skin)
- leg length
- neurologic exam

Investigations
- basic: CBC and differential, blood smear, ESR, CRP, x ray
- as indicated: blood (ANA, RF, culture, viral/bacterial serology, CK, PTT, sickle cell screen, immunoglobulins, complement), urinalysis, synovial fluid (cell count, Gram stain, culture), TB skin test, imaging, bone marrow aspiration, slit lamp exam

Growing Pains

Epidemiology
- age 2-12 yr, M=F

Clinical Presentation
- diagnosis of exclusion
- intermittent, non-articular pain in childhood with normal physical exam findings
- pain at night, often bilateral and limited to the calf, shin, or thigh; typically short-lived
- relieved by heat, massage, mild analgesics
- child is well, asymptomatic during the day, no functional limitation
- possible family history of growing pains

Management
- lab investigations not necessary if typical presentation; reassurance and supportive management

Transient Synovitis of the Hip

Epidemiology
- age 3-10 yr, M:F, more common on right side

Clinical Presentation
- afebrile or low-grade fever, pain typically occurs in hips, knees (referred from hip); painful limp but full ROM (pain not as pronounced as in joint or bone infections), child does not look "toxic"
- pain is not disabling and gradually worsens over few days, can have sudden onset of symptoms
- symptoms resolve over 7-10 d

Investigations
- WBC within normal limits; ESR and CRP may be mildly elevated
- joint effusions may be seen on ultrasound
  - aspirate joint and examine synovial fluid if suspicious for septic arthritis
  - MRI if suspicious for osteomyelitis or periarticular pyomyositis
- diagnosis of exclusion

Treatment
- symptomatic and anti-inflammatory medications
  - usually resolves with 24-48 h

Complications
- Legg-Calve-Perthes Disease

Red Flags for Limb Pain
- Fever
- Pinpoint pain/tenderness
- Pain out of proportion to degree of inflammation
- Night pain
- Weight loss
- Erythema
**Septic Arthritis and Osteomyelitis**

- MEDICAL EMERGENCY

---

**Juvenile Idiopathic Arthritis**

- a heterogeneous group of conditions characterized by persistent arthritis in children <16 yr
- diagnosis: arthritis in ≥1 joint(s); duration ≥6 wk; onset age <16 yr old; exclusion of other causes of arthritis; classification defined by features/number of joints affected in the first 6 mo of onset

### Systemic Arthritis (Still’s Disease)

- onset at any age, M=F
- onset or twice daily fever spikes (>38.5°C) ≥2 d/wk with temperature returning below baseline; children usually acutely unwell during fever episodes
- extra-articular features: erythematous “salmon-coloured” maculopapular rash, lymphadenopathy, hepatosplenomegaly, thrombocytosis, anemia, arthritis
- arthritis may occur weeks to months later
- high ESR, CRP, WBC, platelet count

### Oligoarticular Arthritis (1-4 joints)

- most common type of JIA
  - onset early childhood (<5 years of age), F>M
  - persistent: affects no more than 4 joints during the disease course
  - extended: affects more than 4 joints after the first 6 mo
  - typically affects large joints: knee most common, elbows, wrists; hip involvement unusual
  - ANA positive ~60-80%, RF negative
  - screening eye exams for asymptomatic anterior uveitis (occurs in ~30%)
  - complications: knee flexion contracture, quadriiceps atrophy, leg-length discrepancy, growth disturbances, uveitis

### Polyarticular Arthritis (5 or more joints)

- ANA positive in 50%, uveitis in 10%
- RF negative (usually negative)
  - onset: 2-4 yr and 6-12 yr, F>M
- symmetrical involvement of large and small joints of hands and feet, TMJ, cervical spine
- RF positive
  - onset late childhood/early adolescence, F>M
  - similar to the aggressive form of adult rheumatoid arthritis
  - severe, rapidly destructive, symmetrical arthritis of large and small joints
  - may have rheumatoid nodules at pressure points (elbows, knees)
  - unremitting disease, persists into adulthood

### Enthesitis-Related Arthritis

- onset: late childhood/adolescence, M>F
- arthritis and/or enthesitis (inflammation at the site where tendons or ligaments attach to the bone)
- weight bearing joints, especially hip and intertarsal joints
- risk of developing ankylosing spondylitis in adulthood

### Psoriatic Arthritis

- onset: 2-4 yr and 9-11 yr, F>M
- arthritis and psoriasis OR arthritis and at least two of:
  - dactylitis, nail pitting or other abnormalities, or family history of psoriasis in a 1st degree relative
  - asymmetric or symmetric small or large joint involvement
Management
- goals of therapy: eliminate inflammation, prevent joint damage, promote normal growth and development as well as normal function, minimize medication toxicity
- exercise to maintain ROM and muscle strength
- multidisciplinary approach: OT/PT, social work, orthopedics, ophthalmology, rheumatology
- 1st line drug therapy: NSAIDs, intra-articular corticosteroids
- 2nd line drug therapy: DMARDs (methotrexate, sulfasalazine, leflunamide), corticosteroids (acute management of severe arthritis, systemic symptoms of JIA, topical eye drops for uveitis), biologic agents (IL1, IL6 inhibition for systemic arthritis, TNF antagonist for polyarticular JIA)

Reactive Arthritis
- see Rheumatology, RH24
- arthritis (typically the knee) follows bacterial infection, especially with Salmonella, Shigella, Yersinia, Campylobacter, Chlamydia, and most commonly Streptococcus (post-streptococcal reactive arthritis)
- typically resolves spontaneously
- may progress to chronic illness or Reiter's syndrome (urethritis, conjunctivitis)

Lyme Arthritis
- see Infectious Diseases, ID23
- caused by spirochete Borrelia burgdorferi
- incidence highest among 5-10 yr olds
- do not treat children <8 yr old with doxycycline (may cause permanent tooth discoloration)

Systemic Lupus Erythematosus
- see Rheumatology, RH11
- autoimmune illness affecting multiple organ systems
- incidence 1/1,000, more commonly age >10, F:M = 10:1
- childhood-onset SLE vs. adult-onset SLE: children have more active disease, are more likely to have renal disease, and children receive more intensive drug therapy and have a poorer prognosis

Vasculitides
HENOCHE-SCHÖNLEIN PURPURA
most common vasculitis of childhood, peak incidence 4-10 yr, M:F = 2:1
- vasculitis of small vessels
- often have history of URTI 1-3 wk before onset of symptoms

Clinical Presentation
- clinical triad: 1) palpable purpura, 2) abdominal pain, 3) arthritis
- skin: palpable, non-thrombocytopenic purpura in lower extremities and buttocks, edema, scrotal swelling
- joints: arthritis/arthritis involving large joints associated with painful edema
- GI: abdominal pain, GI bleeding, intussusception
- renal: microscopic hematuria, IgA nephropathy, proteinuria, HTN, renal failure in <5%

Investigation
- urinalysis (blood, protein creatinine ratio), serum (urea/ electrolytes, creatinine, albumin, elevated IgA)
- skin/renal biopsy – IgA deposition
- ultrasound – intussusception/perforation, testicular pain/swelling
- rule out other autoimmune conditions/vasculitides

Management
- mainly supportive (e.g. elevation for edema)
- anti-inflammatory medications for joint pain, corticosteroids for select patients
- monitor for protein on urinalysis and hypertension every month for 6 mo, checking for renal disease, which may develop late (immunosuppressive therapy if severe)

Prognosis
- self-limited, resolves within 4 wk
- recurrence in about one-third of patients
- long-term prognosis dependent on severity of nephritis
KAWASAKI DISEASE
• acute vasculitis of unknown etiology (likely triggered by infection)
• medium-sized vasculitis with predilection for coronary arteries
• most common cause of acquired heart disease in children in developed countries
• peak age: 3 mo-5 yr; Asians > Blacks > Caucasians

Diagnostic Criteria
• fever persisting ≥5 d AND ≥4 of the following features
  1. bilateral, non-exudative conjunctival injection
  2. oral mucous membrane changes (fissured lips, strawberry tongue, injected pharynx)
  3. changes of the peripheral extremities
    • acute phase: extremity changes including edema of hands and feet or erythema of palms or soles
    • subacute phase: periungual desquamation
  4. polymorphous rash
  5. cervical lymphadenopathy >1.5 cm in diameter (usually unilateral)
• exclusion of other diseases (e.g. scarlet fever, measles)
• atypical Kawasaki disease: fever persisting ≥5 d and 2-3 of the above criteria
  • further evaluation dictated by CRP, ESR, and supplemental laboratory criteria

Management
• initial therapy: IVIG (2g/kg) and high (anti-inflammatory) dose of ASA
• once afebrile >48 h: low (anti-platelet) dose of ASA until platelets normalize, or longer if coronary artery involvement
• IVIg within 10 d of onset reduces risk of coronary aneurysm formation
• baseline 2D-Echo and follow-up periodic 2D Echo (usually at 2, 6 wk)

Complications
• coronary artery vasculitis with aneurysm formation occurs in 20-25% of untreated children, <5% if receive IVIg within 10 d of fever
• 50% of aneurysms regress within 2 yr
• anticoagulation for multiple or large coronary aneurysms
• risk factors for coronary disease: male, age <1 or >9 yr, fever >10 d, Asian or Hispanic ethnicity, thrombocytopenia hyponatremia

Skin Lesions and Masses

Differential Diagnosis of Skin Lesions/Masses

- for background information and medical management, see Dermatology, D5
- for biopsy techniques, see Skin Biopsy Types and Techniques, PL7

Surgical Management of Malignant Skin Lesions

- surgical treatment for all malignant skin lesions involve total excision of the primary lesion
- excision margin of lesion depends on the type of lesion, the lesion diameter, and (for melanoma) the lesion depth
- for decisions regarding reconstruction using flaps or skin grafts, see Reconstruction, PL11

Basic Surgical Techniques

Sutures and Suturing

ANESTHESIA
- irrigate before injecting anesthetic, followed by debridement and more vigorous irrigation

Table 5. Toxic Limit and Duration of Action (1 cc of 1% solution contains 10 mg lidocaine)

<table>
<thead>
<tr>
<th></th>
<th>Without Epinephrine</th>
<th>With Epinephrine (vasoconstrictor, limits bleeding)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lidocaine (Xylocaine)*</td>
<td>5 mg/kg, lasts 45-60 min</td>
<td>7 mg/kg, lasts 2-6 h</td>
</tr>
<tr>
<td>Bupivicaine (Marcaine)* for longer analgesic effect</td>
<td>2 mg/kg, lasts 2-4 h</td>
<td>3 mg/kg, lasts 3-7 h</td>
</tr>
</tbody>
</table>

*Lidocaine toxicity symptoms include: circumoral numbness, light-headedness, and drowsiness followed by tremors and seizures. Cardiac and respiratory signs are late findings.

- for example when using 1% lidocaine without epinephrine in a 70 kg patient:
  - toxic limit = 5 mg x 70 kg = 350 mg
  - max bolus injection = 350 mg / 10 mg/cc = 35 cc (may add more after 30 min)

IRRIGATION AND DEBRIDEMENT
- irrigate copiously with a physiologic solution such as Ringer’s lactate or normal saline to remove surface clots, foreign material, and bacteria
- use a 19 gauge needle and 35 cc syringe to generate ~25-35 psi when irrigating
- debride all obviously devitalized tissue; irregular or ragged wounds must be excised to produce sharp wound edges that will assist healing when approximated
- wounds left unapproximated ≥8 h should be debrided and copiously irrigated to ensure wound edges are optimized for healing
- there is high risk of infection for any wound closed primarily after 8 h

SUTURES
- use of a particular suture material is highly dependent on surgeon preference; however, skin should be closed with a non-absorbable material when traumatic mechanisms are involved

Table 6. Suture Materials: Absorbable vs. Non-absorbable and Monofilament vs. Multifilament

<table>
<thead>
<tr>
<th>Suture Materials</th>
<th>Uses</th>
<th>Examples</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Absorbable</td>
<td>Deep sutures under short-term tension</td>
<td>Plain gut®, Vicryl®, Polysorb®, Biosyn®, Monocryl®, Caproyn®, chromic gut, fast absorbing gut</td>
<td>Loses at least 50% of their strength in 4 wk; eventually absorbed</td>
</tr>
<tr>
<td>Non-absorbable</td>
<td>Skin closure</td>
<td>Nylon, polypropylene (Prolene®), stainless steel, silk, ticon, ethibond</td>
<td>Lower likelihood of wound dehiscence, more difficult to tie, makes track marks</td>
</tr>
<tr>
<td>Monofilament</td>
<td>Everyday use and optimal for contaminated and infected wounds (lower likelihood of bacterial trapping in suture material)</td>
<td>Monosof®, Monocryl®, Biosyn®, Prolene®</td>
<td>Slides through tissue with less friction; more memory/stiffness; more difficult to tie; requires multiple throws (lower knot security)</td>
</tr>
<tr>
<td>Multifilament</td>
<td>AVOID in contaminated wounds (increased likelihood of bacterial trapping)</td>
<td>Vicryl® and Silk, Ticon, Ethibond</td>
<td>Less memory/stiffness, thus easier to work with (higher knot security)</td>
</tr>
</tbody>
</table>

BASIC SUTURING TECHNIQUES

Basic Suture Methods
- simple interrupted: can be used in almost all situations
- sub-cuticular: good cosmetic result but weak, used in combination with deep sutures; not used in trauma
- vertical mattress: for areas difficult to evert (e.g. volar hand)
- horizontal mattress: evertting, time-saving
- continuous over and over (i.e. “running”, “baseball stitch”): time-saving, good for hemostasis

Other Skin Closure Materials
- tapes: may be indicated for superficial wounds and those with opposable edges. Tape cannot be used on actively bleeding wounds. When placed across the incision, will prevent surface marks and can be used primarily or after surface sutures have been removed
- skin adhesives: e.g. 2-octylcyanoacrylate (e.g. Dermabond®) works well on small areas without much tension or shearing; may cause irreversible tattooing
- staples: steel-titanium alloys that incite minimal tissue reaction (healing is comparable to wounds closed by suture)
Excision

- plan your incision along relaxed skin tension lines to minimize appearance of scar
- use elliptical incision to prevent “dog ears” (heaped up skin at end of incision), so the length of the ellipse should be approximately 3x the width
- if needed, undermine skin edges to decrease wound tension
- use layered closure including dermal sutures decreases tension

Skin Biopsy Types and Techniques

SHAVE BIOPSY
- used for superficial lesions where sampling of the full thickness of the dermis is not necessary or practical
- most suitable for shave biopsies are benign lesions either elevated above the skin or have pathology confined to the epidermis (e.g. seborrheic or actinic keratoses, skin tags, and warts)
- high risk of recurrence with shave biopsy for any lesions, including actinic or seborrheic keratoses
- rapid, requires little training, and does not require sutures for closure
- heals by secondary intent (moist dressings should be used)
- should not be used for pigmented lesions – an unsuspected melanoma cannot be properly staged if partially removed

NEEDLE BIOLOGY
- 21 G for lymph node biopsy
- Trucut® needle biopsy for breast masses suspected for carcinoma

INCISIONAL BIOPSY
- can be a punch biopsy, an ellipse within the lesion, or a narrow margin excision of the lesion
- gives pathologists a portion of the lesion and the border with normal skin
- punch biopsies involve the removal of a core-shaped piece of tissue to allow sampling of the deep dermis; performed with round, disposable knives ranging in diameter from 2-10 mm
- punch biopsy wounds can be closed with suture or left to heal by secondary intention. Punches greater than 3 mm may produce scarring and are best closed with one or two sutures
- punch biopsies have a low incidence of infection, bleeding, non-healing, and significant scarring

EXCISIONAL BIOPSY
- performed for lesions that require complete removal for diagnostic purposes
- performed for lesions that cannot be adequately punch biopsied due to size or depth
- for small pigmented lesions and atypical moles; if concerned about melanoma, can do a narrow margin excision for the diagnosis and treatment of small pigmented lesions and atypical moles
- best for small lesions that are easily removed and primarily closed
- requires the greatest amount of expertise and time
- always requires sutures for closure

TECHNIQUE

General
- all shave and punch biopsies performed in clinic are done using aseptic technique, but are not sterile
- sterile gloves are indicated for biopsies and excisions in all patients

Preparing the Site
- common skin antisepsics (Betadine®, chlorhexidine) can be used to prepare the biopsy site
- chlorhexidine is used in concentrations ranging from 0.5-4% The higher concentration cannot be used on the face, as it could get into the eyes or ears and may burn or cause damage. Most chlorhexidine preps also contain alcohol, which can be flammable, so allow to dry before the biopsy and certainly before using any cautery
- Betadine® (7.5% povidone–iodine) may be safer for the head and neck (as to avoid the above problems with chlorhexidine) and around the eyes and ears
- mark the intended lesion and surgical margins with a surgical marker, since they may be temporarily obliterated following injection of the anesthetic
- for all biopsies, a sterile drape technique is indicated. A fenestrated surgical drape is placed around the biopsy site after the area is cleansed and anesthetized

Anesthesia
- most commonly used local anesthetic is 1% or 2% lidocaine (with epinephrine)
- small amounts of epinephrine are added to constrict blood vessels, decrease bleeding, prolong anesthesia, and limit lidocaine toxicity. The local with epinephrine can be injected directly into the lesion
- local anesthetics with epinephrine may be used anywhere in the body, including the digits (except if the digits have been significantly injured and could have vascular compromise – e.g. saw injury)
- epinephrine should only be avoided in patients with history of vascular compromise if injecting into an area that is compromised
Wounds

• wound: disruption of the normal anatomical relationships of tissue as a result of injury

Types of Wounds

• laceration: cut or torn tissue
• abrasion: superficial skin layer is removed, variable depth
• contusion: injury caused by forceful blow to the skin and soft tissue; entire outer layer of skin intact, yet injured
• avulsion: tissue/limb forcefully separated from surrounding tissue, either partially or fully; “de-gloving”
• puncture wounds: cutaneous opening relatively small as compared with depth (e.g. needle), including bite wounds
• crush injuries: caused by compression
• burns: thermal, chemical, electrical
• ulcers

STAGES OF WOUND HEALING

• growth factors released by tissues play an important role
• scar is mature once it has completed the final stage, usually after 1-2 yr

PHASE

1. Inflammatory Phase (Reactive) (Days 1-6)
   • Limits damage, prevents further injury
   • Debris and organisms cleared via inflammatory response:
     • Neutrophils (24-48 h)
     • Macrophages: critical to wound healing by orchestrating growth factors for collagen production (48-96 h)
     • Lymphocytes: role poorly defined (5-7 d)

2. Proliferative Phase (Regenerative) (Day 4 – Week 3)
   • Fibroblasts attracted and activated by macrophage growth factors
   • Reparative process: re-epithelialization, matrix synthesis, angiogenesis (relieves ischemia)
   • Tensile strength begins to increase at 4-5 d

3. Remodeling Phase (Maturation) (Week 3 – Year 1)
   • Increasing collagen organization and stronger crosslinks
   • Type I collagen replaces Type III until normal 4:1 ratio achieved
   • Peak tensile strength at 60 d – 80% of pre-injury strength

PROCESS

1. Hemostasis – vasoconstriction + platelet plug
   2. Chemotaxis – migration of macrophages and PMN

1. Collagen synthesis (mainly type III)
   2. Angiogenesis
   3. Epithelialization

1. Contraction
   2. Scarring
   3. Remodeling of scar

Figure 15. Stages of wound healing
TYPES OF WOUND HEALING

Primary (1°) Healing (First Intention)
- definition: wound closure by direct approximation of edges within hours of wound creation (i.e. with sutures, staples, skin graft, etc.)
- indication: recent (<6 h, longer with facial wounds) clean wounds
- contraindications: animal/human bites (except on face), crush injuries, infection, long time lapse since injury (>6-8 h), retained foreign body

Secondary (2°) Healing/ Spontaneous Healing (Second Intention)
- definition: wound left open to heals spontaneously (epithelialization occurs at 1 mm/d from wound margins in concentric pattern, contraction [myofibroblasts], and granulation) – maintained in inflammatory phase until wound closed; requires dressing changes; inferior cosmetic result
- indication: when 1° closure not possible or indicated (see Primary Healing)

Tertiary (3°) Healing/ Delayed Primary Healing (Third Intention)
- definition: intentionally interrupts healing process (e.g. with packing, sharp debridement), then wound can be closed primarily at 4-10 d post-injury after granulation tissue has formed and there is <105 bacteria/gram of tissue
- indication: contaminated (high bacterial count), long time lapse since initial injury, severe crush component with significant tissue devitalization, closure of fasciotomy wounds
- prolongation of inflammatory phase decreases bacterial count and lessens chance of infection after closure

ABNORMAL HEALING

Hypertrophic Scar
- definition: scar remains roughly within boundaries of original scar
- red, raised, widened, frequently pruritic
- common sites: back, shoulder, sternum
- treatment: scar massage, pressure garments, silicone gel sheeting, corticosteroid injection, surgical excision if other options fail (however, may still recur)
- often improve slowly over time

Keloid Scar
- definition: scar grows outside boundaries of original scar
- red, raised, widened, frequently pruritic
- caused by:
  - genetic factors (highest rates in African Americans, Asians)
  - endocrine factors
  - excess tension on wound or delayed closure (as in burn wounds)
- common sites: central chest, back, shoulders, deltoid, ear, angle of mandible
- treatment: multimodal therapy including: pressure garments, silicone gel sheeting, corticosteroid injection, surgical excision with post-surgical management if other options fail (however, there is a high chance of recurrence), fractional carbon dioxide ablative laser, radiation

Spread Scar
- characterized by having exactly the same order of collagen fibres as normal scars
- clinically, a typical spread scar is flat, wide, and often dent
- treatment: surgical excision and closure

Chronic Wound
- wound fails to achieve primary wound healing within 4-6 wk
- common chronic wounds include: diabetic, pressure, and venous stasis ulcers
- treatment: may heal with meticulous wound care; may also require surgical intervention
- Marjolin’s ulcer: squamous cell carcinoma arising in a chronic wound secondary to genetic changes caused by chronic inflammation → always consider biopsy of chronic wound

Infected Wounds

Definitions
- the presence of bacteria within a wound may be divided into 4 categories:
  - contamination: the presence of non-replicating microorganisms within a wound
  - colonization: the presence of replicating microorganisms within a wound
  - critical colonization: increasing bacterial burden; have delayed healing but may not exhibit classic signs of infection
  - infection: the presence of >10⁵ microorganisms in a wound without intact epithelium or small amounts of a very virulent organism (e.g. GBS); have delayed healing and exhibit classic signs of infection
- signs of infection: redness, swelling, pain, clinically unwell

Risk Factors for Infection
- Virulence of the infecting microorganism
- Amount of bacteria present
- Host resistance
- Immunocompromised host
Management of Acute Contaminated Wound (<24 h)
- cleanse and irrigate open wound with physiologic solution (NS or RL) using sufficient pressure
- evaluate for injury to underlying structures (vessels, nerve, tendon, and bone)
- control active bleeding; previously closed wounds may require suture removal in order to drain any pus and allow for thorough irrigation and debridement
- debridement: removal of foreign material, devitalized tissue, old blood
- surgical debridement: blade and irrigation if indicated
- systemic antibiotics are commonly indicated for obvious infection. Risk factors include: wound >8 h, severely contaminated, human/animal bites, immunocompromised, involvement of deeper structures (e.g., joints, fractures)
- tetanus prophylaxis (see Table 8 and Figure 16)
- ± post-exposure treatment of:
  - hepatitis B, HIV, hepatitis C (if titres confirmed at 6 mo)
- re-evaluate in 24-48 h for signs of superficial or deep infection
- if evidence of infection (i.e., erythema, warmth, pain, discharge), open infected portion of wound by removing sutures, swab sample for culture and sensitivity, irrigate wound and allow healing by secondary intention

Management of Late Contaminated Wounds (>24 h, including ulcers)
- tetanus prophylaxis (see Table 8 and Figure 16)
- irrigation and debridement
- traumatic tattooing can occur if foreign materials left in wound
- systemic antibiotics
- topical antimicrobials: beneficial for minor wounds, but no additional benefit for wounds requiring systemic antibiotics. May aid in healing of chronic wounds
- closure: final closure via secondary intention (most common), delayed wound closure (3rd closure), skin graft, or flap; successful closure depends on bacterial count of ≤105/cm3 prior to closure and frequent dressing changes

BITES
- see Emergency Medicine, ER47

Dog and Cat Bites
- pathogens: *Pasteurella multocida, S. aureus, S. viridans*
- investigations
  - radiographs prior to therapy to rule out foreign body (e.g. tooth) or fracture
  - culture for aerobic and anaerobic organisms, Gram stain
- treatment: Clavulins® (amoxicillin + clavulanic acid) 500 mg PO q8h started immediately
  - consider rabies prophylaxis if animal has symptoms of rabies or unknown animal
  - ± rabies Ig (20 IU/kg around wound, or IM) and 1 of the 3 types of rabies vaccines (1.0 mL IM in deltoid, repeat on days 3, 7, 14, 28)
- aggressive irrigation with debridement
- healing by secondary intention is mainstay of treatment
- only consider primary closure for bite wounds on the face; otherwise primary closure is contraindicated
- contact Public Health if animal status unknown

Human Bites
- pathogens: *Staphylococcus*, β-hemolytic *Streptococcus*, *Eikenella corrodens*, *Bacteroides*
- mechanism: most commonly over dorsal MCP from a punch in mouth; “fight-bite”
- serious, as mouth has 109 microorganisms/mL, which get trapped in joint space when fist unclenches and overlying skin forms an air-tight covering ideal for anaerobic growth – can lead to septic arthritis
- investigations
  - radiographs prior to therapy to rule out foreign body (e.g. tooth) or fracture
  - culture for aerobic and anaerobic organisms, Gram stain
- treatment
  - urgent surgical exploration of joint, drainage, and debridement of infected tissue
  - wound must be copiously irrigated
  - Clavulin® 500 mg PO q8h or (if penicillin allergy) clindamycin 300 mg PO q6h + ciprofloxacin 500 mg PO q12h + secondary closure
  - splint

Dressings
- dressing selection depends on the wound characteristics and surgeon preference
  - as the wound progresses through healing, it will require different types of dressings; therefore, routine inspection is recommended
  - principles of dressing clean vs. infected wounds
    - clean wounds can be dressed with non-adherent dressing (which is non-adhering to epithelializing tissue); requires secondary dressing
    - infected wounds may need debridement and antibiotics and can be dressed with iodine gauze, silver-containing dressings, or antimicrobial dressings
  - moist vs. dry wounds
    - purpose of dressings should be to promote moist wound healing i.e. moistening dry wounds or drying (removing excess exudate/blood) wet wounds
  - wide-based vs. cavitary/tunnelling wounds
    - cavity or tunnelling wounds (i.e. through a fascial layer) can be packed with saline-soaked ribbon gauze (non-infected) or Betadine®-soaked ribbon gauze (infected)

Negative-pressure wound therapy or vacuum-assisted closure (VAC) uses sealed vacuum dressings that suction wound fluid and promote increased blood flow to enhance the healing process. VACs may be placed under deep wounds or to enhance skin graft take.

Adapted from Grabb & Smith’s Plastic Surgery, 6th ed. Chapter 3, Table 3.3

Reconstruction

**RECONSTRUCTION LADDER**

**Definition**
- an approach to wound management with successively more complex methods of treatment
- surgeons should start with the least complex method and progressively increase in complexity as appropriate

**SKIN GRAFTS**

**Definition**
- tissue composed of epidermis and varying degrees of dermis, that does not carry its own blood supply. Survival requires the generation of new blood vessels from the recipient site bed

**Donor Site Selection**
- must consider size, hair pattern, texture, thickness of skin, and colour (facial grafts best if taken from “blush zones” above clavicle e.g. pre/post auricular or neck)
- partial thickness grafts usually taken from inconspicuous areas (e.g. buttocks, lateral thighs, etc.)

**Partial Thickness Skin Graft Survival**
- 3 phases of skin graft “take”
  1. plasmatic imbibition: diffusion of nutrition from recipient site (first 48 h)
  2. inosculation: vessels in graft connect with those in recipient bed (d 2-3)
  3. neovascular ingrowth: graft revascularized (d 3-5)
- requirements for graft survival
  - well-vascularized bed (recipient site). Unsuitable beds include: bone, tendon, heavily irradiated, infected wounds, etc.
  - good contact between graft and recipient bed. Staples, sutures, splinting, and pressure dressings are used to prevent movement/ shearing of graft and hematoma or seroma formation
  - low bacterial count at recipient site (<10^5/cm^3, to prevent infection)
  - common reasons for graft loss: hematoma/seroma, infection, mechanical force (e.g. shearing, pressure)

**Classification of Skin Grafts**
1. by species
   - autograft: from same individual
   - allograft (homograft): from same species, different individual
   - xenograft (heterograft): from different species (e.g. porcine)
2. by thickness: see Table 10
## Table 10. Skin Grafts

<td>Requires well vascularized bed</td>
</tr>
<tr>
<td><strong>Uses</strong></td>
<td>Large areas of skin, granulating tissue beds</td>
<td>Face (colour match), site where thick skin or decreased contracture is desired (e.g. finger)</td>
</tr>
</tbody>
</table>

*Primary: immediate reduction in size upon harvesting; Secondary: reduction in size once graft placed on wound bed and healing has occurred

### Meshed Grafts (split thickness grafts can be meshed after harvest by a mesher to a variety of ratios)
- **advantages**
  - prevents accumulation of fluids (e.g. hematoma, seroma)
  - covers a larger area
  - best for contaminated recipient site
- **disadvantages**
  - poor cosmesis (“alligator hide” appearance)
  - has significant contraction

## FLAPS
- **definition**: tissue of varying composition (skin and fat, muscle and fat, bone and fat, muscle only, etc.), that has a known blood supply (random, pedicled, or named); not dependent on neovascularization, unlike a graft
- **may consist of**: skin, subcutaneous tissue, fascia, muscle, tendon, bone, other tissue (e.g. omentum)
- **classification**: based on tissue composition, blood supply to skin (random, axial), and location of the donor site (local, regional, distant)
- **indications for flaps**
  - replaces tissue loss due to trauma or surgery (reconstruction)
  - provides skin and temporary soft tissue coverage through which surgery can be carried out later
  - to aid healing or treatment of infection by providing vascularized tissue to a poorly vascularized bed
- **complications**: flap loss due to hematoma, seroma, infection, poor flap design, extrinsic compression (dressing too tight) or vascular failure/thrombosis, fat necrosis (in free and pedicled flaps)
Random Pattern Flaps
- blood supply by dermal and subdermal plexus to skin and subdermal tissue with random vascular supply
- limited length:width ratio to ensure adequate blood supply (typically 3:1 in the head and neck, 1-2:1 elsewhere)
- flap choice is often a combination of available tissue, type of tissue needed, location of reconstruction site with respect to donor site, blood supply, ability to close the donor site and surgeon preference
- types
  - rotation: semicircular tissue rotated around a pivot point for defect closure; commonly used on sacral pressure sores, scalp, and cheek defects
  - transposition: tissue is transposed (i.e. lifted up from its native location and brought into the defect) around a pivot point from one location to another; commonly used on certain areas of the face using adjacent areas of excess skin laxity
  - Z-plasty: two triangular flaps are repositioned; used to reorient a scar, lengthen the line of a scar, or to break up a scar
  - advancement flaps (V-Y, Y-V): defect is closed with uni-directional tissue advancement
    - single/bipedicle V-Y flaps: wounds with lax surrounding tissue; the pedicle is the deep tissue underlying the flap

Axial Pattern Flaps (Arterialized)
- flap contains a well-defined artery and vein
- allows greater length:width ratio (5-6:1)
- types
  - peninsular flap: skin and vessel intact in pedicle
  - island flap: vessel remains intact, but is skeletonized such that the pedicle is better defined
  - free flap: vessel is cut and re-anastomosed in a different anatomical location by microsurgical techniques
- can be sub-classified according to tissue content of flap
  - e.g. musculocutaneous/myocutaneous (e.g. transverse rectus abdominal myocutaneous) vs. fasciocutaneous

Free Flaps
- transplanting expendable donor tissue from one part of the body to another by isolating and dividing a dominant artery and vein to a flap, and performing a microsurgical anastomosis between these and the vessels in the recipient wound
- survival rates >95%
- types: muscle and skin (common), bone, jejunum, omentum, fascia
  - e.g. radial forearm, scapular, latissimus dorsi

<td>Cellulitis</td>
<td>Full thickness of skin with subcutaneous tissue involvement</td>
</tr>
<tr>
<td>Fasciitis</td>
<td>Fascia</td>
</tr>
<tr>
<td>Myositis</td>
<td>Muscle</td>
</tr>
</tbody>
</table>

**Erysipelas**

**Definition**
- acute skin infection that is more superficial than cellulitis

**Etiology**
- typically caused by Group A β-hemolytic Streptococcus

**Clinical Features**
- intense erythema, induration, and **sharply demarcated borders** (differentiates it from other skin infections)

**Treatment**
- penicillin or first-generation cephalosporin (e.g. cefazolin or cephalixin)

**Cellulitis**

**Definition**
- non-suppurative infection of skin and subcutaneous tissues

**Etiology**
- skin flora are most common organisms: S. aureus, β-hemolytic Streptococcus
- immunocompromised: Gram-negative rods and fungi

**Clinical Features**
- source of infection
  - trauma, recent surgery
  - PVD, DM – cracked skin in feet/toes
  - foreign bodies (IV, orthopedic pins)
  - systemic symptoms (fever, chills, malaise)
- pain, tenderness, edema, erythema with poorly defined margins, regional lymphadenopathy
- can lead to ascending lymphangitis (visible red streaking in skin proximal to area of cellulitis)

**Investigations**
- CBC, blood cultures
- culture and Gram stain a collection/aspirate from wound if open wound
- plain radiographs show soft tissue edema only

**Treatment**
- antibiotics: first line – cephalexin 500 mg PO q6h or cloxacillin 500 mg PO q6h x 7 d; if complicated (e.g. lymphangitis, DM, severe infection, oral antibiotic therapy failure), consider IV cefazolin 1-2 g q8h or IV cloxacillin, IV penicillin. All patients should have reassessment in 48 h for resolution if on oral antibiotic
- outline area of erythema to monitor success of treatment
- immobilize and splint (hands)

**Necrotizing Fasciitis**

**Definition**
- rapidly spreading, very painful infection of the fascia with necrosis of surrounding tissues
- some bacteria create gas that can be felt as crepitus and can be seen on x rays
- infection spreads rapidly along deep fascial plane and is limb-and life-threatening

**Etiology**
- Type I: polymicrobial (less aggressive)
- Type II: monomicrobial, usually β-hemolytic Streptococcus
Ulcers

Clinical Features

• pain out of proportion to clinical findings and beyond border of erythema
• edema, tenderness, ± crepitus (subcutaneous gas from anaerobes), ± flu-like symptoms (e.g. nausea, fever, diarrhea, dizziness, malaise)
• overlying skin changes including blistering and ecchymoses
• patients may look deceptively well at first, but may rapidly become very sick/toxic
• late findings
  • skin turns dusky blue and black (secondary to thrombosis and necrosis)
  • induration, formation of bullae
  • cutaneous gangrene, subcutaneous emphysema

Investigations

• a clinical diagnosis
• CT scan only if suspect it is not necrotizing fasciitis (looking for abscess, gas collection, myonecrosis and possible source of infection)
• severely elevated CK: usually means myonecrosis (late sign)
• bedside incision, exploration, and incisional biopsy when ruling out conditions, clinical presentation is not supportive, or difficult exam
• during incisional biopsy, often see “dish water pus” (Group A infection) and a hemostat easily passed along fascial plane (fascial biopsy to rule out in equivocal situations)

Treatment

• vigorous resuscitation (ABCs)
• urgent surgical debridement: remove all necrotic tissue, copious irrigation with plans for repeat surgery in 24-48 h
• IV antibiotics: as appropriate for clinical scenario; consider penicillin 4 million IU IV q4h and/or clindamycin 900 mg IV q6h until final cultures available (the combination can be synergistic if Group A strep)
• urgent consultation with infectious disease specialist is recommended

Lower Limb Ulcers

Traumatic Ulcers (Acute)

• failure of wound to heal, usually due to compromised blood supply and unstable scar, secondary to pressure or bacterial colonization/infection
• usually over bony prominence ± edema ± pigmentation changes ± pain
• treatment: involvement of vascular surgery. Any debridement of ulcer and compromised tissues must be preceded by ABIs and vascular Doppler. Ulcers or compromised tissues left to heal via secondary intention with dressings may need reconstruction with local or distant flap in select cases, vascular status of limb must be assessed clinically and via vascular studies (i.e. ABI, duplex Doppler)

Non-Traumatic Ulcers (Chronic)

Necrotizing Soft-Tissue Infection: Diagnosis and Management

Summary: Necrotizing soft tissue infections (NSTIs) are highly lethal. Establishing the diagnosis of NSTI can be the main challenge in treating patients with NSTI. The mainstay of treatment is early and complete surgical debridement, combined with antimicrobial therapy, close monitoring, and physiologic support. Novel therapeutic strategies, including hyperbaric oxygen and intravenous immunoglobulin, have been described, but their effect is controversial. Identification of patients at high risk of mortality is essential for selection of patients that may benefit from future novel treatments and for development and comparison of future trials.

</tr>
</tbody>
</table>

Pressure Ulcers

**Common Sites**
- over bony prominences; 95% on lower body

**Stages of Development**
1. hyperemia: disappears 1 h after pressure removed
2. ischemia: follows 2-6 h of pressure
3. necrosis: follows >6 h of pressure
4. ulcer: necrotic area breaks down – N.B. skin is like tip of an iceberg

**Classification** (National Pressure Ulcer Advisory Panel 2014)
- Stage I: non-blanchable erythema present >1 h after pressure relief, skin intact
- Stage II: partial-thickness skin loss
- Stage III: full-thickness skin loss into subcutaneous tissue
- Stage IV: full-thickness skin loss into muscle, bone, tendon, or joint
- if an eschar is present, must fully debride before staging possible
- Stage X: unstageable ulcer

**Prevention**
- good nursing care (clean dry skin, frequent repositioning), special beds or pressure relief surface, proper nutrition, activity early identification of individuals at risk (e.g. immobility, incontinence, paraplegia, immunocompromised, DM, etc.)

**Treatment**
- depends on individual patient and condition
- treat underlying medical issues including nutrition
- continue with preventative measures (pressure relief, assess for pressure points e.g. wheelchairs; manage continence issues, divert contaminants e.g. urine and feces)
- wound debridement, moisture retentive or antimicrobial dressing, regular reassessment
- systemic antibiotics for infections
- assess for possible reconstruction

**Complications**
- cellulitis, osteomyelitis, sepsis, gangrene
Burns

Burn Injuries

Causal Conditions
- thermal (flame contact, scald)
- chemical
- radiation (UV, medical/therapeutic)
- electrical

Most Common Etiology
- children: scald burns
- adults: flame burns

</tbody>
</table>

Pathophysiology of Burn Wounds

- amount of tissue destruction is based on temperature, time of exposure, and specific heat of the causative agent
- zone of hyperemia: vasodilation from inflammation; entirely viable, cells recover within 7 d; contributes to systemic consequences seen with major burns
- zone of stasis (edema): decreased perfusion; microvascular sludging and thrombosis of vessels results in progressive tissue necrosis → cellular death in 24–48 h without proper treatment
- factors favouring cell survival: moist, aseptic environment, rich blood supply
- zone where appropriate early intervention has most profound effect in minimizing injury zone of coagulation (ischemia): no blood flow to tissue → irreversible cell damage → cellular death/necrosis

Diagnosis and Prognosis

- burn size
  - % of TBSA burned: rule of 9s for 2nd and 3rd burns only (children <10 yr old use Lund-Browder chart)
  - for patchy burns, surface area covered by patient’s palm (fingers closed) represents approximately 1% of TBSA
- age: more complications if <3 yr or >60 yr old
- depth: difficult to assess initially – history of etiologic agent and time of exposure helpful (see Table 16)
- location: face and neck, hands, feet, perineum are critical areas requiring special care of a burn unit (see Indications for Transfer to Burn Centre, PL21)
- inhalation injury: can severely compromise respiratory system, affect fluid requirement estimation (underestimate), mortality secondary to ARDS
- associated injuries (e.g. fractures)
- comorbid factors (e.g. concurrent disability, alcoholism, seizure disorders, chronic renal failure) can exacerbate extent of injury, other trauma

Figure 19. Zones of thermal injury

Blood vessels and nerves are found in the dermis

Prognosis best determined by burn size (TBSA), age of patient, presence/absence of inhalation injury

Circumferential burns can restrict respiratory excursion and/or blood flow to extremities and require escharotomy

TBSA does not include areas with 1st burns
Burn Size And Survival Probability In Paediatric Patients In Modern Burn Care: A Prospective Observational Cohort Study
Lancet 2012 Mar 17;379(9820):1013-21
Study: Single-centre prospective observational cohort study using clinical data for paediatric patients with burns of at least 30% of their total body surface area (TBSA). Patients were stratified by burn size in 10% increments, ranging from 30% to 100% TBSA.
Results: 952 severely burned paediatric patients were admitted to the centre between 1998 and 2008. 123 (13%) patients died, 154 (16%) developed multiorgan failure, and 89 (9%) had sepsis. Burn size of 62% TBSA was a crucial threshold for mortality.
Conclusions: In a modern paediatric burn care setting, a burn size of roughly 60% TBSA is a crucial threshold for postburn morbidity and mortality. We recommend that paediatric patients with greater than 60% TBSA burns be immediately transferred to a specialised burn centre. Furthermore, patients should be treated with increased vigilance and improved therapies at the burn centre, in view of the increased risk of poor outcome associated with this burn size.

Indications for Transfer to Burn Centre

American Burn Association Criteria

- patients with partial or full-thickness burns that involve the hands, feet, genitalia, face, eyes, ears, and/or major joints or perineum
- partial thickness burns ≥20% TBSA in patients aged 10-50 yr old
- partial thickness burns ≥10% TBSA in children aged ≤10 or adults aged ≥50 yr old
- full thickness burns ≥5% TBSA in patients of all ages
- electrical burns, including lightning (internal injury underestimated by TBSA), and chemical burns
- inhalation injury (high risk of mortality and may lead to respiratory distress)
- burn injuries in patients with medical comorbidities, could complicate management and recovery
- any patient with simultaneous trauma plus burns should be stabilized for trauma first, then triaged appropriately to burn centre
- any patients with burn injury and who will require special emotional, social, and rehabilitation intervention
- children with burns in a hospital not equipped with pediatric care specialists

Acute Care of Burn Patients

- adhere to ATLS protocol
- resuscitation using Parkland formula to restore plasma volume and cardiac output. Parkland formula is a starting estimate and patients may require more volume. Other formulas exist, but the Parkland formula is predominately used in North America
  - 4 cc/kg x %TBSA (greater than first degree) x wt(kg) (1/2 within first 8 h of sustaining burn, 1/2 in next 16 h)
- extra fluid administration required if
  - burn >80% TBSA
  - 4° burns
  - associated traumatic injury
  - electrical burn
  - inhalation injury
  - delayed start of resuscitation
  - pediatric burns
- monitor resuscitation
  - urine output is best measure: maintain at >0.5 cc/kg h (adults) and 1.0 cc/kg/h in children <12 yr
  - maintain a clear sensorium, HR <120/min, MAP >70 mmHg
- burn specific care
  - relieve respiratory distress: intubation and/or escharotomy
  - escharotomy in circumferential extremity burn, including digits
  - prevent and/or treat burn shock: 2 large bore IVs for fluid resuscitation
  - insert Foley catheter to monitor urine output
  - identify and treat immediate life-threatening conditions (e.g. inhalation injury, CO poisoning)
  - determine TBSA affected first, since depth is difficult to determine initially (easier to determine after 24 h)
- tetanus prophylaxis if needed
  - all patients with burns >10% TBSA, or deeper than superficial-partial thickness, need 0.5 cc tetanus toxoid
  - also give 250 U of tetanus Ig if prior immunization is absent/unclear, or the last booster >10 yr ago
- baseline laboratory studies (Hb, U/A, BUN, CXR, electrolytes, Cr, glucose, CK, ECG, cross-match if traumatic injury, ABG, carboxyhemoglobin)
- cleanse, debride, and treat the burn injury (antimicrobial dressings)
- early excision and grafting important for outcome

Respiratory Problems

3 major causes

- burn eschar encircling chest
  - distress may be apparent immediately
  - perform escharotomy to relieve constriction
- CO poisoning
  - may present immediately or later
  - treat with 100% O₂ by facemask (decreases half-life of carboxyhemoglobin from 210 to 59 min) until carboxyHb <10%
- smoke inhalation leading to pulmonary injury
  - chemical injury to alveolar basement membrane and pulmonary edema (insidious onset)
  - risk of pulmonary insufficiency (up to 48 h) and pulmonary edema (48-72 h)
  - watch for secondary bronchopneumonia (3-25 d) leading to progressive pulmonary insufficiency
  - intubate patient with any signs of inhalation injuries

Inhalation Injuries 101

- Indicators of inhalation injury
- Injury in a closed space
- Facial burn
- Singed nasal hair/eyebrows
- Soot around nares/oral cavity
- Hoarseness
- Conjunctivitis
- Tachypnea
- Carbon particles in sputum
- Elevated blood CO levels (i.e. brighter red)
- Suspected inhalation injury requires immediate intubation due to impending airway edema; failure to diagnose inhalation injury can result in airway swelling and obstruction, which, if untreated, can lead to death
- Neither CXR or ABG can be used to rule out inhalation injury
- Direct bronchoscopy now used for diagnosis
- Signs of CO poisoning (headache, confusion, coma, arrhythmias)
Burn Wound Healing

</tbody>
</table>

Treatment

- 3 stages
  1. assessment: depth determined
  2. management: specific to depth of burn and associated injuries
  3. rehabilitation
- first degree
  - treatment aimed at comfort
  - topical creams (pain control, keep skin moist) ± aloe
  - oral NSAIDs (pain control)
- superficial second degree/partial thickness
  - daily dressing changes with topical antimicrobials (such as polysporin); leave blisters intact unless circulation impaired or over joint and inhibiting motion
- deep second degree/deep partial thickness and third degree/full thickness
  - prevent infection and sepsis (significant complication and cause of death in patients with burns)
    - most common organisms: *S. aureus*, *P. aeruginosa*, and *C. albicans*
      - day 1-3 (rare): Gram-positive
      - day 3-5: Gram-negative (*Proteus, Klebsiella*)
    - topical antimicrobials: treat colonized wounds (from skin flora, gut flora, or caregiver)
    - remove dead tissue
    - surgically debride necrotic tissue, excise to viable (bleeding) tissue

</tbody>
</table>

Risk Factors for Infection of Burn Wounds

**Patient Related**
- Extent >30% TBSA
- Depth: full-thickness and deep partial-thickness
- Patient age (higher risk with very young and very old)
- Comorbidities
- Wound dryness
- Wound temperature
- Secondary impairment of blood flow to wound
- Acidosis

**Microbial Factors**
- Density >10^5 organisms per gram of tissue
- Motility
- Virulence and metabolic products (endotoxin, exotoxin, permeability factors, other factors)
- Antimicrobial resistance
• early excision and grafting is the mainstay of treatment for deep/full thickness burns
• initial dressing should decrease bacterial proliferation
• prevention of wound contractures: pressure dressings, joint splints, early physiotherapy

Other Considerations in Burn Management

Figure 22. Systemic effects of severe burns

- nutrition
  • hypermetabolism: TBSA >40% have BMR 2-2.5x predicted
  • consider nutritional supplementation e.g. calories, vitamin C, vitamin A, Ca++, Zn++, Fe++
- immunosuppression and sepsis
  • must keep bacterial count <105 bacteria/g of tissue (blood culture may not be positive)
  • signs of sepsis: sudden onset of hyper/hyperthermia, unexpected CHF or pulmonary edema, development of ARDS, ileus >48 h post-burn, mental status changes, azotemia, thrombocytopenia, hypofibrinogenemia, hyper/hypoglycemia (especially if burn >40% TBSA)
- GI bleed may occur with burns >40% TBSA (usually subclinical)
  • treatment: tube feeding or NPO if there is a GI bleed, antacids, H2 blockers (preventative)
  • renal failure secondary to under resuscitation, drugs, myoglobin, etc.
  • progressive pulmonary insufficiency
  • can occur after: smoke inhalation, pneumonia, cardiac decompensation, sepsis
- wound contracture and hypertrophic scarring (outcomes optimized with timely wound closure, splinting, pressure garments) and physiotherapy

Special Considerations

CHEMICAL
• major categories: acid burns, alkaline burns, phosphorous burns, chemical injection injuries
• common agents: cement, hydrofluoric acid, phenol, tar
• mechanism of injury: chemical solutions coagulate tissue protein leading to necrosis
  • acids → coagulation necrosis
  • alkalines → saponification followed by liquefactive necrosis
• severity related to: type of chemical (alkali worse than acid), temperature, volume, concentration, contact time, site affected, mechanism of chemical action, degree of tissue penetration
• burns are deeper than they initially appear and may progress with time

Treatment (General)
• ABCs, monitoring
• remove contaminated clothing and brush off any dry powders before irrigation
• irrigation with water for 1-2 h under low pressure (contraindicated in heavy metal burns, such as sodium, potassium, magnesium, and lithium; in these cases, soak in mineral oil instead)
• inspect eyes, if affected: wash with saline and refer to ophthalmology
• inspect nails, hair, and webspaces
• correct metabolic abnormalities and tetanus prophylaxis if necessary
• contact poison control line if necessary
• local wound care 12 h after initial dilution (debridement)
• wound closure same as for thermal burn
• beware of underestimated fluid resuscitation, renal, liver, and pulmonary damage

Special Burns and Treatments

<table>
<thead>
<tr>
<th>Burn Type</th>
<th>Treatment/Management</th>
</tr>
</thead>
<tbody>
<tr>
<td>Acid Burn</td>
<td>Water irrigation, followed by dilute solution of sodium bicarbonate</td>
</tr>
<tr>
<td>Hydrofluoric Acid</td>
<td>Water irrigation; clip fingernails to avoid acid trapping; topical calcium gel ± subcutaneous injection of calcium gluconate ± 10% calcium gluconate IV depending on amount of exposure and pain</td>
</tr>
<tr>
<td>Sulfuric Acid</td>
<td>Eat with soap/lime prior to irrigation, as direct water exposure produces extreme heat</td>
</tr>
<tr>
<td>Tar</td>
<td>Remove with repeated application of petroleum-based antibacterial ointments (e.g. Polysporin®)</td>
</tr>
</tbody>
</table>
ELECTRICAL BURNS
- depth of burn depends on voltage and resistance of the tissue (injury more severe in tissues with high resistance)
- often presents as small punctate burns on skin, with extensive deep tissue damage which requires debridement
- electrical burns require ongoing monitoring, as latent injuries can occur
  - watch for system-specific damages and abnormalities
    - abdominal: intraperitoneal damage
    - bone: fractures and dislocations especially of the spine and shoulder
    - cardiopulmonary: anoxia, ventricular fibrillation, arrhythmias
    - muscle: myoglobinuria indicates significant muscle damage → compartment syndrome
    - neurological: seizures and spinal cord damage
    - ophthalmology: cataract formation (late complication)
    - renal: ATN resulting from toxic levels of myoglobin and hemoglobin
    - vascular: vessel thrombosis → tissue necrosis (increased Cr, K+, and acidity), decrease in RBC (beware of hemorrhages/delayed vessel rupture)

Treatment
- ABCs, primary and secondary survey, treat associated injuries
- beware of cardiac arrhythmias (continue cardiac monitoring)
- monitor: hemorrhochromogenuria, compartment syndrome, urine output
- wound management: topical agent with good penetrating ability (silver sulfadiazine or mafenide acetate)
- debride nonviable tissue early and repeat prn (every 48 h) to prevent sepsis
- amputations frequently required

FROSTBITE
- see Emergency Medicine, ER46

</tr>
</tbody>
</table>

Range of Motion

| Tendons, bones, joints, nerves | Assess active and passive range of motion of wrist: extension/flexion/ulnar/radial deviation; finger abduction/adduction/flexion/extension, thumb flexion/extension/abduction/adduction/opposition |

Tendons

| FDP | Stabilize PIP in extension, ask patient to flex fingers (at DIP) |
| FDS | Stabilize non exam fingers in extension (neutralizes FDP) and ask patient to flex examination finger (at PIP) |

Palpation

| Bones | Focal tenderness or abnormal alignment |
| Joints | Instability may indicate ligamentous injury or dislocation |

General Management of Hand Injuries

Nerves

- test the nerve function BEFORE putting in local anesthesia
- primary repair for a clean injury within 7 d and without concurrent major injuries; secondary repair if >7 d (may require nerve graft)
- epineural repair of all digital nerves with minimal tension
- post-operative: dress wound, elevate hand, and immobilize
- Tinel’s sign (cutaneous percussion over the repaired nerve) produces paresthesias and defines level of nerve regeneration
  - Wallerian degeneration occurs in the first 2 wk, which is why there is no Tinel’s sign until after this time period
  - a peripheral nerve regenerates at 1 mm/d
  - paresthesias felt at area of percussion because regrowth of myelin (Schwann cells) is slower than axonal regrowth → percussion on exposed free-end of axon generates paresthesia

Vessels

- often associated with nerve injury (anatomical proximity)
- control bleeding with direct pressure and hand elevation
- if digit devascularized, optimal repair within 6 h
- close skin, then dress, immobilize, and splint hand with fingertips visible
- monitor colour, capillary refill, skin turgor, fingertip temperature post-revascularization

Tendons

- most tendon lacerations require primary repair
- many tendons are repaired in the emergency room, flexors are repaired in the operating room within 2 wk
- avoid excessive immobilization after repair (specific protocols for flexors to minimize stiffness and facilitate rehabilitation)

Bones

- see Fractures and Dislocations, PL27

Nailbed

- subungual hematomas >50% of the nail surface area need to be drained (trephination), done under a digital block by puncturing nail plate
- if suspecting greater severity of injury (e.g. distal phalanx displaced fracture, laceration of nail bed), remove nail plate to examine underlying nailbed under digital block anesthesia
- irrigate wound and nail thoroughly
- suture repair of nailbed with chromic suture
- replace cleaned nail, which acts as a splint for any underlying distal phalangeal fracture and prevents adhesion formation between nail fold and nailbed
Hand Infections

Principles
- trauma is most common cause
- 5 cardinal signs: rubor (red), calor (hot), tumour (swollen), dolor (painful), and functio laesa (loss of function)
- 90% caused by Gram-positive organisms
- most common organisms (in order) – S. aureus, S. viridans, Group A Streptococcus, S. epidermidis, and Bacteroides melaninogenicus (MRSA is becoming more common)

TYPES OF INFECTIONS

Deep Space Infections
- abscess formation in deep spaces of the hand, most commonly thenar or mid-palm space
- uncommon, there are 9 spaces in the hand

Felon
- definition: abscess in the pulp of a fingertip or thumb that occurs following a puncture wound into the pad of the digit; may be associated with osteomyelitis (akin to compartment syndrome and can lead to skin necrosis)
- treatment: elevation, warm soaks, cloxacillin 500 mg PO q6h (if in early stage); if obvious abscess or pressure on the overlying skin or failure to resolve with conservative measures, then needs I&D, take cultures/gram stain and adjust antibiotics to culture results

Flexor Tendon Sheath Infection
- Staphylococcus > Streptococcus > Gram-negative rods
- definition: abscess within the flexor tendon sheath (flexor tenosynovitis), commonly caused by a penetrating injury and can lead to tendon necrosis and rupture if not treated; it is often suppurative; however, there can be very little pus early on
- clinical features: Kanavel’s 4 cardinal signs
  1. point tenderness along flexor tendon sheath
  2. severe pain on passive extension of digit
  3. fusiform swelling of entire digit
  4. flexed posture (increased comfort)
- treatment
  - OR I&D, copious irrigation and debridement, IV antibiotics, resting hand splint until infection resolves, aggressive hand therapy after

Herpetic Whitlow
- HSV-1, HSV-2
- definition: painful vesicle(s) around fingertip or thumb
  - often found in medical/dental personnel and children
- clinical features: can be associated with fever, malaise and lymphadenopathy, prodromal phase
  - patient is infectious until lesion has completely healed
- treatment: diagnosed clinically, if in doubt confirm with viral culture/PCR or Tzanck smear, usually self-limited, consider oral acyclovir in severe cases; I&D is contraindicated

Paronychia
- acute = Staphylococcus; chronic = Candida
- definition: infection (granulation tissue) of soft tissue around fingernail (within the paronychium and/or beneath eponychial fold)
- etiology
  - acute paronychia: a “hangnail”, artificial nails, and nail biting
  - chronic paronychia: prolonged exposure to moisture
- treatment
  - acute paronychia: warm compresses and oral antibiotics if caught early; if abscess present, drainage with blade (avoid hitting nail bed) and oral/IV antibiotics; if abscess extends to below nail plate, nail plate removal may be required
  - chronic paronychia: anti-fungals, eponychial marsupialization, nail plate removal may be required
Amputations

Hand or Finger
- emergency management: injured patient and amputated part require attention
  - patient: x-rays (stump and amputated part), NPO, clean wound and irrigate with NS, dress stump with nonadherent dressing, cover with dry sterile dressing, tetanus and antibiotic prophylaxis (cephalosporin/erythromycin)
  - amputated part: x-rays, gently irrigate with RL, wrap amputated part in a NS/RL soaked sterile gauze and place inside waterproof plastic bag, place in a container, then place container on ice
- indications for replantation
  - age: children often better results than adults
  - level of injury: thumb and multiple digit amputations are higher priority; multiple level amputation is a contraindication to replant
  - nature of injury: clean cut injuries have greater success; avulsion and crush injuries are relative contraindications to replant
- if replant contraindicated, manage stump with revision amputation
  - involves debriding stump of wound, trimming back the bone and nerve endings, and gently closing the skin
  - commonly done in the ER under digital block

Tendons

Common Extensor Tendon Deformities

Table 21. Extensor Tendon Deformities

Figure 23. (A) Mallet finger deformity (B) Boutonnière deformity (C) Swan neck deformity

De Quervain’s Tenosynovitis
- definition: tenosynovitis is inflammation of the tendon and/or its sheath. Most common is De Quervain’s tenosynovitis (inflammation of the extensor tendons in the 1st dorsal compartment [APL and EPB])
- clinical features
  - +ve Finkelstein’s test (pain over the radial styloid induced by making fist, with thumb in palm, and ulnar deviation of wrist)
  - pain localized to the 1st extensor compartment
  - tenderness and crepitation over radial styloid may be present
  - differentiate from CMC joint arthritis (CMC joint arthritis will have a positive grind test, whereby crepitus and pain are elicited by axial pressure to the thumb)

Figure 24. Zone of extensor tendon injury (odd numbered zones fall over a joint)
• treatment
  • mild: NSAIDs, splinting and steroid injection into the tendon sheath (successful in over 60% of cases)
  • severe surgery to open 1st dorsal compartment and release stenotic tendon sheaths of APL and EPB

Ganglion Cyst
• definition
  • fluid-filled synovial lining that protrudes between carpal bones or from a tendon sheath; most commonly carpal in origin
  • most common soft tissue tumour of hand and wrist (60% of masses)
• clinical features
  • most commonly on the dorsal wrist overlying the scapholunate ligament, followed by the volar surface of the wrist overlying the radioscaphoid or scaphotrapezial joints
  • 3 times more common in women than in men
  • more common in younger individuals (2nd to 4th decades)
  • can be large or small – may drain internally so size may wax and wane
  • often non-tender although tenderness increased when cyst is smaller (from increased pressure within smaller cyst sac)
• treatment
  • conservative treatment: do nothing
  • aspiration (recurrence rate 30-60%)
  • steroid injection if painful (done in combination with aspiration, as results alone are no better than aspiration)
  • consider operative excision of cyst and stalk (recurrence rate 5.9% for dorsal wrist ganglion, 30% for volar)

Common Flexor Tendon Deformities
• flexor tendon zones (important for prognosis of tendon lacerations)
  • "no-man’s land" (zone 2) (see Figure 24)
    • between distal palmar crease and mid-middle phalanx
    • zone where superficialis and profundus lie ensheathed together
    • recovery of glide very difficult after injury

Stenosing Tenosynovitis (trigger finger/thumb)
• definition: inflammation and thickening of tendon or tendon sheath/pulley (most commonly at A-1 pulley near MCP), preventing smooth gliding of tendon through the sheath/pulley and resulting in locking of thumb or finger in flexion/extension
• etiology: idiopathic or associated with RA, DM, hypothyroidism, gout, and pregnancy
• clinical features
  • ring finger is most commonly affected, then long finger and thumb
  • patient complains of catching, snapping, or locking of affected finger
  • tenderness to palpation/nodule at palmar aspect of MCP over A-1 pulley
  • women are 4 times more likely to be affected than men
• non-surgical treatment
  • NSAIDs
  • steroid injection; injections less likely to be successful in patients >60 yr, or symptoms greater than 6 mo
  • splint
• surgical treatment
  • indicated if no relief of symptoms or minimal relief with steroids
  • incise A-1 flexor pulley to permit unrestricted, full active finger motion

Fractures and Dislocations
• for fracture principles, see Orthopedics, OR4

FRACTURES
• about 90% of hand fractures are stable in flexion (splint to prevent extension)
• position of safety
  • wrist extension 0-30°
  • MCP flexion 70-90°
  • IP full extension
  • this is done if you want to immobilize a fracture but are not sure whether there are other injuries
• stiffness secondary to immobilization is the most important complication; Tx = early motion

Distal Phalanx Fractures
• most commonly fractured bone in the hand
• usual mechanism is crush injury, and thus accompanied by soft tissue injury
• subungual hematoma is common and must be decompressed, especially if there is involvement of >50% of the nail surface area
• injury involving >50% of the nail surface area often suggests a nail bed laceration, in which the patient would benefit from nail plate removal and nailbed repair surgery
• treatment consists of 3 wk of digital splinting (immobilize the DIP with a STAX splint); if intra-articular fracture displaced >30%, then percutaneous pinning (K-wires) and splint

Proximal and Middle Phalanx Fractures
• check for: rotation, scissoring (overlap of fingers on making a fist), shortening of digit
• non-displaced or minimally displaced: closed reduction (if extra-articular), buddy tape to neighbouring stable digit, elevate hand, motion in guarded fashion early, splinted for 2-3 wk
• displaced, non-reducible, not stable with closed reduction, or rotational or scissoring deformity: percutaneous pinning (K-wires) or ORIF, and splint

Metacarpal Fractures
• generally accept varying degrees of deviation before reduction required: up to 10° (D2), 20° (D3), 30° (D4), or 40° (D5)
• Boxer’s fracture: acute angulation of the neck of the 5th metacarpal into palm
  • mechanism: blow on the distal-dorsal aspect of closed fist
  • loss of prominence of metacarpal head, volar displacement of head
  • up to 30-40° angulation may be acceptable
  • if greater angulation, closed reduction should be considered to decrease the angle
  • if stable, ulnar gutter splint for 4-6 wk
• Bennett’s fracture: two-piece fracture/dislocation of the base of the thumb metacarpal, usually intra articular
  • unstable fracture
  • APL pulls MC shaft proximally and radially, causing adduction of thumb
  • treat with percutaneous pinning or ORIF, followed by thumb spica x 6 wk
• Rolando fracture: T- or Y-shaped fracture of the base of the thumb metacarpal
  • treated like a Bennett’s fracture

DISLOCATIONS
• must be reduced as soon as possible
• dislocation vs. subluxation
  • dislocation: severe injury where articular surfaces of a joint are no longer in contact with one another
  • subluxation: articular surfaces of a joint are partially out of place (i.e. “partial dislocation” – often unstable and requires reduction)

PIP and DIP Dislocations (PIP more common than DIP)
• usually dorsal dislocation (commonly from hyperextension)
  if closed dislocation: closed reduction and splinting in position of function for 1 wk or buddy taping, and early mobilization (prolonged immobilization causes stiffness)
• open injuries are treated with wound care, irrigation, and debridement, followed by closed or open reduction and antibiotics

MCP Dislocations (relatively rare)
• dorsal dislocations much more common than volar dislocations
• dorsal dislocation of proximal phalanx on metacarpal head; most commonly index finger (hyperextension)
  • two types of dorsal dislocation
    • simple (reducible with manipulation): treat with closed reduction and splinting for 2-4 wk at 60-70° MCP flexion
    • complex (irreducible - most commonly due to volar plate blocking the reduction): treat with open reduction

Ulnar Collateral Ligament (UCL) Injury
• forced abduction of thumb (e.g. ski pole injury)
• Skier’s thumb: acute UCL injury – if stable, treated with splint x 6-8 wk; if unstable, patient may have Stener lesion
• Gamekeeper’s thumb: chronic UCL injury, often requires open repair and tendon graft for stabilization
• Stener Lesion: the distal portion of the UCL can detach and flip superficial to the adductor aponeurosis and will not appropriately heal – requires open repair
• evaluation: radially deviate thumb MCP joint in full extension and at 30° flexion and compare with non-injured hand. UCL rupture is presumed if injured side deviates more than 30° in full extension or more than 15° in flexion
**Dupuytren’s Disease**

**Definition**
- proliferative disorder of the palmar fascia, forming nodules (usually painless), fibrous cords, and flexion contractures at the MCP and interphalangeal joints
- flexor tendons not involved
- Dupuytren's diathesis: male sex, early age of onset, strong family history (autosomal dominant inheritance), involvement of multiple digits, bilateral involvement, and involvement of sites other than palmar aspect of hand, including the plantar fascia (Ledderhose’s) and the penis (Peyronie’s) – (see Urology, U30)

**Epidemiology**
- unusual in patients from African and Asian countries, high incidence in northern Europeans, men > women, often presents in 5th-7th decade of life; associated with but not caused by alcohol use, smoking, and DM

**Clinical Features**
- nodules, cords and contractures of MCP, PIP, DIP
- order of digit involvement (most common to least common) ring > little > long > thumb > index
- risk of recurrence

**Treatment**
- palmar pit or nodule: no surgery (steroid injections for pain) palpable band/cord with no limitation of extension (i.e. no contracture) of either MCP or PIP: no surgery
- MCP contracture >30 degrees or PIP contracture of any degree: needle aponeurotomy, collagenase injection, or surgical fasciectomy
- contractures impeding function and/or hygiene: needle aponeurotomy, collagenase injection, or surgical fasciectomy
- MCP joints have better outcomes than PIP joints post-treatment (achievement of near full extension, lower risk of recurrence)

**Carpal Tunnel Syndrome**

**Definition**
- median nerve compression at the level of the flexor retinaculum/transverse carpal ligament

**Etiology**
- median nerve entrapment at wrist
- primary cause is idiopathic
- secondary causes: space occupying lesions (tumours, hypertrophic synovial tissue, fracture callus, and osteophytes), metabolic and physiological (pregnancy, hypothyroidism, acromegaly, and RA); job/hobby related repetitive trauma, especially forced wrist flexion

**Epidemiology**
- female:male = 4:1, most common entrapment neuropathy

**Clinical Features**
- classically, patient awakened at night with numb/painful hand, relieved by shaking/dangling/rubbing
- on exam, sensory loss in median nerve distribution (see Figure 4), but thenar eminence sensory loss is spared (palmar cutaneous branch given off prior to carpal tunnel)
- decreased light touch and 2-point discrimination at DIP adial and ulnar creases; discriminative touch often lost first
- advanced cases: thenar wasting/weakness due to involvement of the motor branch of the nerve
- ± Tinel's sign (tingling sensation on percussion of nerve)
- ± Phalen's sign (wrist flexion induces symptoms)

**Investigations**
- clinical diagnosis
- NCV and EMG studies may be used to objectively confirm the diagnosis

**Treatment**
- avoid repetitive wrist and hand motion, wrist splints at night and when repetitive wrist motion required
- conservative: night-time splinting to keep wrist in neutral position
- medical: NSAIDs local corticosteroids injection (relief from local corticosteroid injections is also diagnostic)
- surgical decompression: transverse carpal ligament incision to decompress median nerve
- indications for surgery: persistent signs and symptoms of median nerve compression not relieved by conservative management
Brachial Plexus

Etiology
- common causes of brachial plexus injury: complication of childbirth and trauma
- other causes of injury: compression from tumours, ectopic ribs

Common Palsies

Table 22. Named Neonatal Palsies of the Brachial Plexus

<table>
<thead>
<tr>
<th>Palsy</th>
<th>Location of Injury</th>
<th>Mechanism of Injury</th>
<th>Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>Duchenne-Erb Palsy</td>
<td>Upper brachial plexus (C5-C6)</td>
<td>Head/shoulder distraction (e.g., motorcycle)</td>
<td>“Waiter’s tip deformity” (shoulder internal rotation, elbow extension and pronation, wrist flexion)</td>
</tr>
<tr>
<td>Klumpke’s Palsy</td>
<td>Lower brachial plexus (C7-T1)</td>
<td>Traction on abducted arm</td>
<td>“Claw hand” May include Horner’s syndrome</td>
</tr>
</tbody>
</table>

Differential Diagnosis of Adult-Acquired Brachial Plexus Palsies
- trauma (blunt, penetrating)
  - associated with large cervical rib, anomalous first rib, strenuous arm work, neck muscle hypertrophy
  - neurogenic: compression of brachial plexus, resulting in upper limb paresthesia, pain, and weakness
  - vascular: compression/thrombosis of subclavian artery/vein, resulting in pain; pallor and Raynaud’s if arterial; swelling and cyanosis if venous
- tumour
  - schwannoma: well-defined margins enable total resection
  - neurofibromas: associated with neurofibromatosis type I
  - other: e.g., Pancoast syndrome (apical lung tumour)
- neuropathy (compressive, post-irradiation, viral, diabetic, idiopathic)

Investigations
- EMG
- MRI: gold standard for identifying soft tissue masses and nerve roots
- CT myelogram: controversial, although some people think that it is better than MRI for identification of nerve root avulsion
- closed injuries: if avulsion suspected, then CT myelogram or MRI initially; otherwise, EMG/NCS 6-12 weeks post-injury to assess healing progress
- open injuries: OR for exploration within a few days post-injury (once patient stable)

Management

Table 23. Management of Brachial Plexus Injuries

<tr>
<td>Open Injuries</td>
<td>Sharp or vascular injury Explore immediately in OR</td>
</tr>
</tbody>
</table>
Craniofacial Injuries

- low velocity vs. high velocity injuries determine degree of damage
- fractures cause bruising, swelling, and tenderness → loss of function
- management: most can wait ~5 d for swelling to decrease before ORIF required

Approach to Facial Injuries

- ATLS protocol
- inspect, palpate, clinical assessment for injury to underlying structures (e.g. facial nerve, bony injuries, septal hematoma, ocular involvement, etc.)
- tetanus prophylaxis
- radiological evaluation: CT scan with fine cuts through the orbit
- wound irrigation with NS/RL and remove foreign materials
- conservative debridement of detached or nonviable tissue
- repair at the time of presentation with 4-0 nylon sutures when the patient's general condition allows
- consider intracranial trauma; rule out skull fracture

Investigations

- CT (gold standard)
  - axial and coronal (specifically request 1.5 mm cuts): for fractures of upper and middle face, as well as mandible
  - indicated for significant head trauma, suspected facial fractures, pre-operative assessment
- panorex radiograph: shows entire upper and lower jaw; best for isolated mandible fracture, but patient must be able to sit; however, if high clinical suspicion and negative panorex, CT should be done

Treatment Goals

- consultation when indicated (dentistry, ophthalmology)
- re-establish normal occlusion if occlusion is an issue
- normal eye function (extraocular eye movements and vision)
- restore stability of face and appearance

Mandibular Fractures

- two points of injury since it is a ring structure (includes fractures and dislocations)
- commonly at sites of weakness (condylar neck, angle of mandible)

Etiology

- anterior force: bilateral fractures
- lateral force: ipsilateral subcondylar and contralateral angle or body fracture
- note: classified as open if fracture into tooth bearing area (alveolus)

Clinical Features

- pain, swelling, difficulty opening mouth ("trismus")
- malocclusion, asymmetry of dental arch
- damaged, loose, or lost teeth
- palpable "step" along mandible
- numbness in V3 distribution
- intra-oral lacerations or hematoma (sublingual)
- chin deviating toward side of a fractured condyle

Classification

Table 24. Mandibular Fracture Classifications by Anatomic Region

<table>
<thead>
<tr>
<th>Areas/Boundaries</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Symphysis</td>
<td>Midline of the mandible; between the central incisors from the alveolar process through the inferior border of the mandible</td>
</tr>
<tr>

<tr>
<td>Subcondylar</td>
<td>Area below the condylar neck (i.e. sigmoid notch) of the mandible</td>
</tr>
<tr>
<td>Coronoid Process</td>
<td>Area of the coronoid process of mandible</td>
</tr>
</tbody>
</table>

*Most common mandibular fracture type

Signs of Basal Skull Fracture

- Battle's sign (bruised mastoid process)
- Hemotympanum
- Raccoon eyes (peri orbital bruising)
- CSF otorrhea/rhinorrhea

Patients with major facial injuries are at risk of developing upper airway obstruction (displaced blood clots, teeth, or fracture fragments; swelling of pharynx and larynx; loss of support of hyomandibular complex → retrusion of tongue); also at risk of ocular injury.

Figure 27. Mandibular fracture
Treatment
- maxillary and mandibular arch bars wired together (intramaxillary fixation) or ORIF ideally managed within 48 h as indicated by best current evidence
- antibiotics from initial presentation until at least 3 doses post-operatively; if late presentation, may consider treatment with antibiotics for an extended course

Maxillary Fractures

Table 25. Le Fort Classification

<table>
<thead>
<tr>
<th>Type of Fracture</th>
<th>Structures Involved</th>
<th>Anatomical Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Le Fort I</td>
<td>Maxillary sinus</td>
<td>Maxilla divided into 2 segments</td>
</tr>
<tr>
<td>Le Fort II</td>
<td>Pterygoid plates</td>
<td>Maxillary teeth and midsection of the maxilla separated from upper face</td>
</tr>
<tr>
<td>Le Fort III</td>
<td>Pterygoid plates</td>
<td>Detach entire midfacial skeleton from cranial base</td>
</tr>
</tbody>
</table>

Nasal Fractures

Etiology
- lateral force \(\rightarrow\) more common, good prognosis
- anterior force \(\rightarrow\) can produce more serious injuries
- most common facial fracture

Clinical Features
- epistaxis/hemorrhage, deviation/flattening of nose, swelling, periorbital ecchymosis, tenderness over nasal dorsum; crepitis, septal hematoma, respiratory obstruction, subconjunctival hemorrhage

Treatment
- treated for airway or cosmetic issues
- always inspect for and drain septal hematoma as this is a cause of septal necrosis and perforation – completed in the ER with small incision in the septal mucosa followed by packing
- closed reduction with Asch or Walsham forceps under anesthesia, pack nostrils with petroleum or nonadhesive gauze packing, nasal splint for 7 d
- best reduction immediately (<6 h) or when swelling subsides (5-7 d)
- rhinoplasty may be necessary later for residual deformity (30%)

Zygomatic Fractures

Classification
1. fracture restricted to zygomatic arch
2. depressed fracture of zygomatic complex (zygoma)
3. unstable fracture of zygomatic complex (tetrapod fracture) – separations occur at maxilla, frontal bone, temporal bone, and orbital rim

Clinical Features
- 3 most common features (pathognomonic):
  - subconjunctival hemorrhage
  - periorbital ecchymosis (often associated with fractures of the orbital floor)
  - V2 numbness (infraorbital and superior dental nerves)
- flattening of malar prominence (view from above)
- pain over fractures on palpation
- palpable step deformity in bony orbital rim (especially inferiorly)
- ipsilateral epistaxis; trismus
- ophthalmologic evaluation if suspected globe injury

Treatment
- if undisplaced, stable, and no symptoms, then soft diet; no treatment necessary
- undisplaced zygomatic arch fractures can be elevated using Gillies approach (leverage on the anterior part of the zygomatic arch via a temporal incision) or Keane approach (elevation through upper buccal sulcus incision) only if arch is not comminuted
- if arch is comminuted, ORIF is required
- stabilization often unnecessary
- ORIF for displaced or unstable fractures of zygomatic complex
Orbital Floor Fractures

- see Ophthalmology, OP40

Definition
- fracture of floor of orbit: may be a "pure blow-out fracture", which has an intact orbital rim, or can be associated with other fractures (orbital rim fracture and/or zygoma)

Etiology
- blunt force to eyeball → sudden increase in intraorbital pressure (e.g. baseball or fist)

Clinical Features
- check visual fields and visual acuity for injury to globe
- periorbital edema and bruising, subconjunctival hemorrhage
- ptosis, exophthalmos, exorbitis, enophthalmos, or hypoglobus
- orbital rim step-offs with possible infraorbital nerve anesthesia
- vertical dystopia (abnormal displacement of the entire orbital cone in the vertical plane) – assessed by comparing the symmetry of the two pupils by a horizontal line running through the pupil of the unaffected eye
- orbital entrapment
  - clinical diagnosis that is a surgical emergency
  - diplopia with straight gaze: unable to look up or down (entrapment of inferior rectus), limited EOM
  - severe pain or nausea and vomiting with upward globe movement
  - requires urgent ophthalmology evaluation if there are associated visual acuity changes

Investigations
- CT (diagnostic): axial and coronal views – with fine cuts through orbit
- diagnostic maneuver for entrapment is forced duction test (pulling on inferior rectus muscle with forceps to ensure full ROM) under local anesthesia in the OR

Treatment
- surgical repair indicated if: entrapment (urgent), any size defect with enophthalmos (if patient is bothered by it) or persistent diplopia (>10 d)
- reconstruction of orbital floor with bone graft or alloplastic material
- after repair, assess for diplopia: may require additional surgery for strabismus

Complications
- persistent diplopia
- enophthalmos

Superior Orbital Fissure Syndrome
- fracture of SOF causing ptosis, proptosis, anesthesia in V1 distribution, and painful ophthalmoplegia (paralysis of CN III, IV, VI)
- uncommon complication seen in Le Fort II and III fractures (1/130)
- recovery time reported as 4.8-23 wk following operative reduction of fractures

Orbital Apex Syndrome
- fracture through optic canal with involvement of CN II at apex of orbit
- symptoms are the same as SOF syndrome plus vision loss
- treatment is urgent decompression of fracture in optic canal (posterior craniotomy for decompression) or steroids
Breast

Anatomy

Vascular Supply

- Thoracodorsal artery
- Thoracolumbar artery
- Thoracoacromial artery
- Subclavian artery
- Axillary artery
- Lateral thoracic artery
- Internal thoracic artery
- Anterolateral intercostal perforators
- Medial intercostal perforators
- Internal thoracic perforating branches

Innervation

- Innervated in a dermatomal pattern from branches of the thoracic intercostal nerves (T3-6)
- Medially innervated from anterior cutaneous branches of I-VI intercostal nerves
- Laterally innervated from lateral cutaneous nerve branches of II-VII intercostal nerves
- Laterally and upper portions of the breast innervated by lower fibres of the cervical plexus (C3, C4)
- Nipple areolar complex (NAC)
  - Supplied by anterior and lateral cutaneous branches of intercostal nerve IV
  - Additional innervation by cutaneous branches of intercostal nerves III and VI

Breast Reduction

Indications

- Symptomatic (general symptoms)
  - Musculoskeletal pain (back, strap, neck), chronic headache, paresthesia in upper limb, rash under the breast, breast discomfort and physical impairment
- Breast reduction methods can be classified based on pedicle (i.e. blood supply to the nipple/areolar complex) and skin resection pattern (i.e. the resultant scar)
Table 26. Common Types of Pedicles

<table>
<thead>
<tr>
<th>Pedicle Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Inferior Pedicle</strong></td>
</tr>
<tr>
<td>Most commonly used technique; versatile use in small-large breast reduction</td>
</tr>
<tr>
<td>Critiqued for boxy shape breast along with more extensive scarring (wise pattern skin resection)</td>
</tr>
<tr>
<td>Recommended pedicle width 6-8 cm, 8-10 cm in large breasts</td>
</tr>
<tr>
<td><strong>Superior Pedicle</strong></td>
</tr>
<tr>
<td>Pedicle derived from the internal mammary perforator of the second intercostal space</td>
</tr>
<tr>
<td>Must be thinned to permit inset</td>
</tr>
<tr>
<td><strong>Medial Pedicle</strong></td>
</tr>
<tr>
<td>Modified from horizontal bi-pedicle (Strombeck) techniques</td>
</tr>
<tr>
<td>Blood supplied from internal mammary perforator from third intercostal and potentially fourth intercostal space</td>
</tr>
<tr>
<td><strong>Superomedial Pedicle</strong></td>
</tr>
<tr>
<td>Incorporate the descending artery from second intercostal space as medial pedicle base extended superolaterally to breast meridian</td>
</tr>
</tbody>
</table>

Table 27. Type of Skin Resections/Scar Options

<table>
<thead>
<tr>
<th>Indications</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Inverted T Pattern</strong></td>
<td>Commonly used in association with inferior pedicle</td>
</tr>
<tr>
<td>Large breasts</td>
<td>Large portion of skin removed in horizontal and vertical direction</td>
</tr>
<tr>
<td>Breasts with poor quality skin that are challenging to remodel</td>
<td>Skin integrity important to shape and hold breast parenchyma</td>
</tr>
<tr>
<td><strong>Vertical Pattern</strong></td>
<td>Used in association with superior or medial pedicle</td>
</tr>
<tr>
<td>Skin must be healthy and easy to remodel</td>
<td>Parenchyma needed to shape skin</td>
</tr>
<tr>
<td></td>
<td>No horizontal scar</td>
</tr>
<tr>
<td></td>
<td>Small to moderate reductions</td>
</tr>
</tbody>
</table>

Complications
- NAC necrosis
- sensory alteration of nipple (may vary with type of reduction pattern)
- unsatisfactory scarring, including hypertrophic or keloid scar
- wound healing complications (1-3% in healthy patients, higher in patients with elevated BMI)
- difficulty breastfeeding (potential issue in women of childbearing age)
- asymmetry
- hematoma
- wound infection
Mastopexy (Breast Lift)

Definition
- aesthetic procedure of the breast used to correct for breast ptosis by modifying the contour and size of the breast along with elevating the position of the nipple

Clinical Grading of Ptosis (Regnault Ptosis Grade Scale)
1. minor ptosis (1st degree)
   - nipple at inframammary fold
2. moderate ptosis (2nd degree)
   - nipple below inframammary fold, but above lower breast contour
3. severe ptosis (3rd degree)
   - nipple below inframammary fold and at lower breast contour
4. glandular ptosis
   - nipple above inframammary fold, but breast hangs below fold
5. pseudoptosis
   - nipple above inframammary fold, but breast is hypoplastic and hangs below the fold

Table 28 Type of Skin Resection/Scar Options

<table>
<thead>
<tr>
<th>Type of Skin Resection/Scar Options</th>
<th>Indications</th>
<th>Description</th>
</tr>
</thead>
</table>
| Circumareolar Mastopexy            | Nipple located 1-2.5 cm too low | Originally described as “donut mastopexy”
|                                    |             | Reduce areolar diameter while simultaneously raising nipple (<2 cm)
|                                    |             | Can correct nipple position asymmetry when used unilaterally
|                                    |             | Also increase infra-areolar skin display in ptotic breasts |
| Vertical Mastopexy                 | Grade I - III ptosis | Larger removal than circumareolar
|                                    |             | Raises nipple position and reduces circumareolar skin tension |
|                                    |             | Larger angle between vertical limb and limb length increases with more lower pole skin |
| Inverted T Mastopexy               | Most effective in grade II to III ptosis caused by skin excess attributed to large weight loss | Facilitate nipple elevation and parenchymal redistribution, fixation, and autoaugmentation techniques |
|                                    |             | Large removal of skin in return for greater scar burden |

- mastopexy can be performed through the same incisions as breast reductions

Breast Augmentation

Definition
- procedure designed to increase the size of the breast

Choice of Incision
- position of incision individualized since no single incision is best for all
- 3 commonly used types of incision: periareolar, inframammary crease, transaxillary

Type of Implant
- silicone or saline-filled
- subclassified into various styles of surface and shape

Location of Implant
- implants are commonly placed in the following positions:
  1. submuscular positions
     - implant placed below pectoralis major muscle
     - most commonly in patients that do not have enough tissue to cover the implant
  2. subglandular position
     - implant placed deep to glandular breast tissue but superficial to muscle
  3. subfascial
     - implant placed below the fascia
Gynecomastia

Definition
- benign enlargement of the male breast due to proliferation of the glandular tissue

Clinical Classification
- gynecomastia can be further classified into:
  1. idiopathic
  2. physiologic
     - neonatal: circulating maternal estrogens via placenta
     - pubertal: relative excess of plasma estradiol versus testosterone
     - elderly: decrease circulating testosterone, peripheral aromatization of testosterone to estrogen
  3. pathologic
     - endocrinopathies: excess estrogen, androgen deficiency, deficient production or action of testosterone
     - tumours
     - chronic disease: liver cirrhosis, renal
     - congenital/genetic: Klinefelter's syndrome, androgen resistance
  4. pharmacologic
     - drugs that may interfere with estrogen-testosterone balance including:
       - hormones (estrogens, gonadotropins, exogenous steroids)
       - antiandrogens
         - androgen receptor antagonists (steroidal and non-steroidal)
         - androgen synthesis inhibitors (5a-reductase inhibitors)
         - antagonidrotropins (GnRH analogs, estrogens)
       - recreational drugs (marijuana, heroin, amphetamines)
       - antihypertensives (spironolactone)
  5. massive weight gain
     - for physical exam, investigations, and medical management (see Endocrinology, E47)

Surgical Options
- surgery is the accepted management for gynecomastia
- surgery addresses the three components (breast, fat, skin)
- often involves a combination of liposuction (to remove the fatty portion) and surgical excision through a small periareolar incision (to remove the glandular component)
- patients with significant skin excess may require skin excision as well

Breast Reconstruction
- reconstruction of the breast after cancer or trauma to recreate the breast which is similar to the contralateral breast
- reconstruction can be performed immediately (at the same time as mastectomy), or delayed (as a separate surgery months or years after initial surgery)
- there are alloplastic and autogenous methods of reconstruction, each with its advantages and disadvantages

Table 29. Timing of Immediate Reconstruction vs. Delayed Reconstruction

<table>
<thead>
<tr>
<th>Advantages</th>
<th>Disadvantages</th>
</tr>
</thead>
<tbody>
<tr>
<td>Immediate Reconstruction</td>
<td>Generally best aesthetic outcome; may possibly preserve nipple if oncologically advisable</td>
</tr>
<tr>
<td></td>
<td>Skin viability assessment can be compromised</td>
</tr>
<tr>
<td></td>
<td>Does not require creation of additional skin</td>
</tr>
<tr>
<td></td>
<td>Longer surgical time</td>
</tr>
<tr>
<td></td>
<td>Tissues are not damaged from scarring</td>
</tr>
<tr>
<td></td>
<td>Less time for patient to consider surgical options</td>
</tr>
<tr>
<td></td>
<td>Breast tissue retains size and shape of original breast</td>
</tr>
<tr>
<td></td>
<td>Loss of skin, volume, lateral border or breast and natural landmarks, including IMF</td>
</tr>
<tr>
<td></td>
<td>More time for patients to discuss surgical options</td>
</tr>
<tr>
<td></td>
<td>Resection of irradiated/scarred skin and associated wound healing complications, including risk of reconstructive failure</td>
</tr>
<tr>
<td>Delayed Reconstruction</td>
<td>Best for patients unable or unwilling to have immediate reconstruction</td>
</tr>
<tr>
<td></td>
<td>Likely requires more stages for completion</td>
</tr>
<tr>
<td>For patients who may be getting radiotherapy and undetermined post-surgery oncologic treatment</td>
<td>Provides option of contralateral surgery with reconstruction, if required (i.e. contralateral cancer)</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Nipple Areolar Complex Reconstruction

- nipple reconstruction is usually done as the final step when the patient is satisfied with breast mound creation
- reconstruction can be performed with local anesthetic since many women have decreased sensation in the mastectomy or breast flaps
- it can be done by either a flap, graft, or 3D tattoo

Table 31. Types of Nipple Reconstruction

<table>
<thead>
<tr>
<th>Description</th>
<th>Advantages</th>
<th>Disadvantages</th>
</tr>
</thead>
<tbody>
<tr>
<td>Skate flap</td>
<td>Pedicle elevated above breast mound</td>
<td>Low complication rates</td>
</tr>
<tr>
<td></td>
<td>Lateral aspects of flap are wrapped around central aspect of flap</td>
<td>Donor site morbidity</td>
</tr>
<tr>
<td></td>
<td>Defect mainly closed by skin graft</td>
<td>May have loss of projection over time</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Skin graft required</td>
</tr>
<tr>
<td>CV flap</td>
<td>Utilizes C flap and two V flaps for nipple reconstruction</td>
<td>No grafts required</td>
</tr>
<tr>
<td></td>
<td>Diameter of C flap becomes diameter of reconstructed nipple</td>
<td>Nipple size limited by flap dimensions</td>
</tr>
<tr>
<td></td>
<td>Width of V flaps dictate projection of reconstructed nipple</td>
<td>May have loss of projection over time</td>
</tr>
<tr>
<td></td>
<td>CV closed with primary closure</td>
<td>Tattooing required to match natural areola</td>
</tr>
<tr>
<td>Nipple graft</td>
<td>Tissue commonly from contralateral nipple (nipple share) or labia</td>
<td>Nipple share is an excellent option in patients with contralateral nipple projection &gt; 1 cm</td>
</tr>
<tr>
<td></td>
<td>Two methods for nipple graft:</td>
<td>Donor site morbidity</td>
</tr>
<tr>
<td></td>
<td>• Distal aspect of nipple removed transversely and</td>
<td>Decreased contralateral nipple sensation</td>
</tr>
<tr>
<td></td>
<td>• Defect closed with purse string suture</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Nipple divided in half longitudinally, folded over, and</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>closed with primary closure</td>
</tr>
</tbody>
</table>
Table 32. Types of Areolar Reconstruction

<table>
<thead>
<tr>
<th>Description</th>
<th>Advantages</th>
<th>Disadvantages</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tattoo</td>
<td>Conducted 3-4 months after nipple reconstruction when most of the projection has stabilized</td>
<td>Can provide more accurate colour matching</td>
</tr>
<tr>
<td>Skin graft</td>
<td>Full thickness skin grafts, commonly from inner aspect of thigh or opposite areola</td>
<td>Provides texture and pigment resembling a natural areola</td>
</tr>
</tbody>
</table>

* Tattoo and skin grafting can be used in conjunction

Aesthetic Surgery

Aesthetic Procedures

<table>
<thead>
<tr>
<th>Location</th>
<th>Procedure</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Head/Neck</td>
<td>Hair transplants</td>
<td>Aesthetic improvement of hair growth patterns using hair follicle grafts or flaps</td>
</tr>
<tr>
<td></td>
<td>Otoplasty</td>
<td>Surgical correction of protruding ears</td>
</tr>
<tr>
<td></td>
<td>Forehead/Brow lift</td>
<td>Surgical procedure to lift the forehead and eyebrows</td>
</tr>
<tr>
<td></td>
<td>Rhinoplasty</td>
<td>Surgical procedure to reduce wrinkling and sagging of the face and neck; “face lift”</td>
</tr>
<tr>
<td></td>
<td>Blepharoplasty</td>
<td>Surgical procedure to shape or modify the appearance of eyelids by removing excess eyelid skin ± fat pads</td>
</tr>
<tr>
<td></td>
<td>Rhinoplasty</td>
<td>Surgical reconstruction of the nose ± nasal airway</td>
</tr>
<tr>
<td></td>
<td>Genioplasty</td>
<td>Chin augmentation via osteotomy or synthetic implant to improve contour</td>
</tr>
<tr>
<td>Skin</td>
<td>Chemical peel</td>
<td>Application of one or more exfoliating agents to the skin resulting in destruction of portions of the epidermis and/or dermis with subsequent tissue regeneration</td>
</tr>
<tr>
<td></td>
<td>Dermabrasion</td>
<td>Skin resurfacing with a rapidly rotating abrasive tool; often used to reduce scars, irregular skin surfaces, and fine lines</td>
</tr>
<tr>
<td></td>
<td>Laser resurfacing</td>
<td>Application of laser to the skin which ultimately results in collagen reconfiguration and subsequent skin shrinking and tightening; often used to reduce scars and wrinkles</td>
</tr>
<tr>
<td></td>
<td>Injectable fillers</td>
<td>An injectable substance is used to decrease facial rhytids; can augment lips to create fuller appearance; substances include: collagen, fat, hyaluronic acid, and calcium hydroxyapatite (most common substances include hyaluronic acid and fat)</td>
</tr>
<tr>
<td>Other</td>
<td>Abdominoplasty</td>
<td>Removal of excess skin and repair of rectus muscle laxity (rectus diastasis); ‘tummy tuck’</td>
</tr>
<tr>
<td></td>
<td>Calf augmentation</td>
<td>Augmentation of calf muscle with implants</td>
</tr>
<tr>
<td></td>
<td>Liposuction</td>
<td>Surgical removal of adipose tissue for body contouring (not a weight loss procedure)</td>
</tr>
</tbody>
</table>

Pediatric Plastic Surgery

Craniofacial Anomalies

Table 34. Pediatric Craniofacial Anomalies

<table>
<thead>
<tr>
<th>Definition</th>
<th>Epidemiology</th>
<th>Clinical Features</th>

</thead>
<tbody>
<tr>
<td>Failure of Formation</td>
<td>Transverse absence (congenital amputation)</td>
<td>At any level (often below elbow/wrist)</td>
<td>Early prosthesis</td>
</tr>
<tr>
<td></td>
<td>Longitudinal absence (phocomelia)</td>
<td>Absent humerus Thalidomide association</td>
<td>Physiotherapy + splinting Soft tissue release if splinting fails Distraction osteogenesis (Ilizarov) ± wedge osteotomy Tendon transfer Pollicization</td>
</tr>
<tr>
<td></td>
<td>Radial deficiency (radial club hand)</td>
<td>Radial deviation Thumb hypoplasia M&gt;F</td>
<td>Distraction osteogenesis (Ilizarov) ± wedge osteotomy Tendon transfer Pollicization</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Thumb hypoplasia</td>
<td>Degree ranges from small thumb with all components to complete absence</td>
<td>Depends on degree – may involve no treatment, webspace deepening, tendon transfer, or pollicization of index finger</td>
</tr>
<tr>
<td></td>
<td>Ulnar club hand</td>
<td>Rare, compared to radial club hand Stable wrist</td>
<td>Splinting and soft tissue stretching therapies Soft tissue release (if above fails) Correction of angulation (Ilizarov distraction)</td>
</tr>
<tr>
<td></td>
<td>Cleft hand</td>
<td>Autosomal dominant Often functionally normal (depending on degree)</td>
<td>First web space syndactyly release Osteotomy/tendon transfer (if hypoplastic)</td>
</tr>
<tr>
<td>Failure of Differentiation/ Separation</td>
<td>Syndactyly</td>
<td>Fusion of ≥2 digits 1/3,000 live births M:F = 2:1 Classified as partial/complete Simple (skin only) vs. complex (osseous or cartilaginous bridges)</td>
<td>Surgical separation before 6-12 mo of age Usually good result May require a skin graft to cover the fingers</td>
</tr>
<tr>
<td></td>
<td>Symbrachydactyly</td>
<td>Short fingers with short nails at fingertips</td>
<td>Digital separation Webspace deepening</td>
</tr>
<tr>
<td></td>
<td>Camptodactyly</td>
<td>Congenital flexion contracture (usually at PIP especially 5th digit)</td>
<td>Early splinting Volar release Arthroplasty (rarely)</td>
</tr>
<tr>
<td></td>
<td>Clinodactyly</td>
<td>Radial or ulnar deviation Often middle phalanx</td>
<td>None (usually); if severe, osteotomy with grafting</td>
</tr>
<tr>
<td>Duplication</td>
<td>Polydactyly</td>
<td>Congenital duplication of digits May be radial (increased in Aboriginais and Asians) or central or ulnar (increased in Blacks)</td>
<td>Amputation of least functional digit Usually &gt;1 yr of age (when functional status can be assessed)</td>
</tr>
<tr>
<td>Overgrowth</td>
<td>Macrodactyly</td>
<td>Rare</td>
<td>None (if mild) Soft tissue/bony reduction</td>
</tr>
<tr>
<td>Undergrowth</td>
<td>Brachydactyly</td>
<td>Short phalanges</td>
<td>Removal of nonfunctional stumps Osteotomies/tendon transfers Distraction osteogenesis Phalangeal/free toe transfer</td>
</tr>
<tr>
<td></td>
<td>Symbrachydactyly</td>
<td>Short webbed fingers</td>
<td>As above + syndactyly release</td>
</tr>
<tr>
<td></td>
<td>Brachysyndactyly</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Constriction Band Syndrome</td>
<td>i.e. amniotic (annular) band syndrome</td>
<td>Variety of presentations</td>
<td>Urgent release for acute, progressive edema distal to band in newborn Other reconstruction is case specific</td>
</tr>
<tr>
<td>Generalized Skeletal Abnormality</td>
<td>Achondroplasia, Marfan’s, Madelung’s</td>
<td>Variety of presentations</td>
<td>Treatment depends on etiology</td>
</tr>

Public Health Context

- see Ethical, Legal, and Organizational Medicine, ELOM2 Overview of Canadian Healthcare System for the organization of health care in Canada including the legal foundation and historical context

Definitions

- population health
  - refers to the health of defined groups of people, their health determinants, trends in health, and health inequalities
  - influenced by: physical, biological, social, environmental, and economic factors; personal health behaviours; health care services
  - broader scope vs. public health, accounts for socio-economic, policy, historical issues

- public health
  - "efforts organized by society to protect, promote, and restore the peoples’ health" and prevent morbidity and mortality
  - refers to the practices, programs, policies, institutions, and disciplines required to achieve the desired state of population health

- epidemiology
  - "study of the distribution […] of determinants of disease, health-related states, and events in populations" 

- public health and preventive medicine (formerly called community medicine)
  - the postgraduate study of health and disease in the population or a specified community
  - 5 year Royal College specialty training
  - goal: to identify and address health problems and evaluate the extent to which health services and others address these issues

Public Health Services in Canada

Mission: to promote and protect the health of Canadians through leadership, partnership, innovation, and action in public health (Public Health Agency of Canada)

- local public health units and services within regional health authorities (in most provinces except Ontario, where local public health units are either autonomous or within local government) provide programs and activities for health protection, promotion, and disease prevention at local and regional levels
- catchment-area populations range widely (100s–1,000,000s), covering areas of 15 km² to 1.5 million km²
- the "core functions" of public health include six essential activities (The Organization of Health Services in Canada. AFMC Primer on Population Health and Preventive Medicine in Canada, 5e. Toronto: Elsevier, 2003.): preparing for the LMCC

Preparing for the LMCC

- the AFMC Primer on Population Health is the core text for the LMCC and is available as an online resource on the AFMC website (http://phprimer.afmc.ca)
- For the LMCC exam, it is recommended that you also read Chapter 15 in Shah CP. Public health and preventive medicine in Canada, 5th ed. Toronto: Elsevier, 2003.

Historical Perspective

Over the last century, Public Health has evolved through three main epidemiological phases:

- Infectious diseases: controlled in the more developed world but an issue in less developed countries (e.g. polio, malaria)
- Chronic diseases: chronic diseases and other noncommunicable conditions have increased morbidity and mortality (e.g. heart disease and cancer due to risk factors and/or exposures)
- Re-emerging infectious diseases: new or re-emergent infections emerge due to unfamiliar or new pathogens, inefficient or inappropriate antibiotic use, travel, and global warming (e.g. HIV, drug resistant TB and malaria)

The Association of Faculties of Medicine of Canada Public Health Educators’ Network. The Organization of Health Services in Canada. AFMC Primer on Population Health.
### Legislation and Public Health in Canada

### Determinants of Health

#### Concepts of Health

- **wellness:** “state of dynamic physical, mental, social, and spiritual well-being that enables a person to achieve full potential and have an enjoyable life”
- **disease:** “abnormal, medically-defined changes in the structure or function of the human body”
- **illness:** “an individual’s experience or subjective perception of a lack of physical or mental well-being and consequent inability to function normally in social roles”
- **illness behaviour:** an individual’s actions resulting from and responding to their illness, including their interactions or avoidance of the health care system
- **sickness:** views the individual and their society hold towards a health condition, affecting their thoughts and actions
- **impairment:** “any loss or abnormality of psychological, physiological, or anatomical structure or function”
- **disability:** “any restriction or lack of ability to perform an activity within the range considered normal for a human being”
- **handicap:** a disadvantage for an individual arising due to impairment or disability
- **health:** “the ability to identify and to realize aspirations, to satisfy needs, and to change or cope with the environment. Health is therefore a resource for everyday life, not merely the absence of disease or infirmity”

#### Definitions of Health

- **First multidimensional definition of health, as defined by the WHO in 1948:** “state of complete physical, mental and social well-being and not merely the absence of disease or infirmity”
- **WHO updated the definition (socio-ecological definition) of health in 1986:** “The ability to identify and to realize aspirations, to satisfy needs, and to change or cope with the environment. Health is therefore a resource for everyday life, not the objective of living. Health is a positive concept emphasising social and personal resources, as well as physical capacities”
- **Ottawa Charter for Health Promotion**
- **Other definitions of health have since been proposed that incorporate other dimensions of health (e.g. “Health is a social, economic, and political issue and above all a fundamental human right” – The People’s Charter for Health)**

#### Determinants of Health

- **1974:** The Honourable Marc Lalonde, federal Minister of Health, publishes *A New Perspective on the Health of Canadians* which outlines four factors that determine health: “human biology, environment, lifestyle, and health care organizations.” The idea of determinants of health has since been expanded and refined to include many additional factors

### Social Determinants: Indigenous People’s Health in Canada

- Colonization: subjugation of Indigenous peoples by the Europeans, leading to the loss of lands, cultural practices, and self-government
- Residential schools: placement of children from Indigenous groups in church run, government-funded schools for the purpose of assimilation, resulting in loss of identity, alienation, and abuse, with long-lasting consequences of higher rates of addictions, abusive relationships, and suicide
- Treaties and land claims: inadequate services for those living on reserves leading to poverty and poor quality infrastructure, reflected in disproportionate burden of infectious diseases (e.g. pertussis, Chlamydia, hepatitis, shigellosis)
- Traditional approach to healing: restoring balance in the four realms of spiritual, emotional, mental and physical health of a person acting as an individual, as well as a member of a family, community and nation
- Ideas represented by medicine wheel of First Nations peoples, the Learning Blanket of Inuit peoples, and the Metis tree model of Holistic Lifelong Learning
- Contrast to Western medicine focus of treating illness, leading to challenges for practitioners of Western medicine to meet Aboriginal patients’ needs
- National Aboriginal Health Organization (NAHO) offers 8 guidelines on practicing culturally safe health care for Aboriginal patients including need to allow Aboriginal patients access to ceremony, song, and prayer; the need for information and for family support; guidelines for the appropriate disposal of body parts and for handling death

### New Immigrants to Canada

- Mandatory medical exams on entry to Canada by a designated medical practitioner
- Complete medical examination for all persons of all ages
- Chest x-ray and tape for persons 11 yr of age and over
- Urinalysis for persons 5 yr of age and over
- Syphilis serology for persons 15 yr of age and over
- HIV testing for applicants 15 yr of age and over as well as for those children who have received blood or blood products, have a known HIV-positive mother, or have an identified risk. An ELISA HIV screening test should be done for HIV 1 and HIV 2
- Serum creatinine if the applicant has hypertension (resting blood pressure greater than 140/90 mmHg), a history of treated hypertension, DM, autoimmune disorder, persistent proteinuria, or kidney disorder

Note: this chart delineates the major challenges faced by each group, but the issues listed are not unique to each population.

Disease Prevention

Natural History of Disease
• course of a disease from onset to resolution
  1. pathological onset
  2. presymptomatic stage: from onset to first appearance of symptoms/signs
  3. clinical manifestation of disease: may regress spontaneously, be subject to remissions and relapses, or progress to death

Disease Prevention Strategies
• measures aimed at preventing the occurrence, interrupting through early detection and treatment, or slowing the progression of disease/mitigating the sequelae

Table 3. Levels of Disease Prevention

</tbody>
</table>

Screening (Secondary Prevention)
- "presumptive identification of unrecognized disease or defect by the application of tests, examinations, or other procedures which can be applied rapidly"

Types of Screening
- Mass screening: screening all members of a population for a disease (e.g. phenylketonuria (PKU) and hypothyroidism in all newborns)
- Selective screening: screening of targeted subgroups of the population at risk for a disease (e.g. mammography in women >50 yr old)
- Multiphasic screening: the use of many measurements and investigations to look for many disease entities (e.g. periodic health exam)

Bias in Screening
- Lead-time: false improvement in survival time caused by changing the starting point of measurement, as opposed to real improvements measured from the original starting point (e.g. due to better therapy)
- Lead-time bias: overestimation of survival time ‘from diagnosis’ when the estimate is made from the time of screening, instead of the later time when the disease would have been diagnosed without screening
- Length-time bias: overestimation of the survival time due to screening at one time point including more stable cases than aggressive cases of disease, who may have shorter survival times

![Figure 2. Lead-time bias](image)

Healthy Public Policy
- characterized by an explicit concern for health and equity in all areas of policy and by an accountability for health impact
- main aim: to create a supportive environment to enable people to lead healthy lives, thereby making healthy choices easier for citizens
- government sectors must take into account health as an essential factor when formulating policy and should be accountable for the health consequences of their policy decisions
- methods
  - Fiscal: imposing additional costs (e.g. taxes on tobacco and alcohol)
  - Legislative: implementing legal deterrents (e.g. smoking bans, legal alcohol drinking age)
  - Social: improving health beyond providing universally funded health care (e.g. providing affordable housing)

Source: International Conference on Health Promotion, Adelaide, South Australia (1998)
Measurements of Health and Disease in a Population

MEASURES OF DISEASE OCCURRENCE

Incidence Rate

- number of new cases in a population per unit of person-time

Prevalence

- total number of cases in a population over a defined period of time
- two forms of prevalence
  - point prevalence: assessed at one point in time
  - period prevalence: as above, but all cases over defined time window (including ‘incident’ ones) are included:
    - depends on incidence rate and disease duration from onset to termination (cure or death)
    - favours the inclusion of chronic over acute cases and may underestimate disease burden if those with short disease duration are missed
- prevalence studies are cross-sectional and provide weak evidence for causal inferences
- prevalence figures are useful for determining the extent of a disease and can aid in the planning of facilities and services

Risk Reduction Strategies

- risk reduction: lower the risk to health without eliminating it (e.g. avoiding sun to lower risk of skin cancer)
- harm reduction: tolerance of some degree of risk behaviour, while aiming to minimize the adverse outcomes associated with these behaviours (e.g. needle exchange programs)

Example of Harm Reduction Strategy – Evaluation of a Pilot Medically Supervised Safer Injection Facility

CMAJ 2006;175:1399-1404

Purposes: To evaluate the outcomes of a supervised safer injecting facility facilitating pre-obtaining illicit drugs under supervision of medical staff, conducted over a 2 year period.

Methods: IDUs who used the safer injecting facility included age <30 yr, history of drug use, homelessness, daily heroin and/or cocaine injection, and recent history of overdose. Mean measures of public order problems were taken 6 wk before and 12 wk after initiation of the safer injecting facility. It was found that the mean number of IDUs injecting daily in public, along with the mean number of publicly discarded syringes were reduced by approximately half.

Conclusion: Overall it has been found that the safer injecting facility in Vancouver has been successful in attracting IDUs at increased risk of HIV, overdose, and public injection of substances. This has resulted in lower incidences of public drug use, publicly discarded syringes and sharing of needles. Other studies associated with this one have demonstrated that there has been no increase in the drug dealing, drug related crimes, or rates of new IDUs in the area surrounding the safer injecting facility.

Incidence and Prevalence

Incidence = # of new cases in a time interval

Prevalence = # of existing cases at a point in time

e.g. For Canada in 2011:

HIV incidence rate is 9.5 per 100,000 people
HIV prevalence is 213 per 100,000 people

Top 5 Causes of Mortality in Canada, 2012, by Sex

Female
- Cancer
- Heart disease
- Stroke
- COPD/chronic lower respiratory disease
- Alzheimer’s

Male
- Cancer
- Heart disease
- Accidents
- Stroke
- COPD/chronic lower respiratory disease

Behavior Change

- health education serves to:
  - increase knowledge and skills
  - encourage positive behaviour changes and discourage unhealthy choices
- health education is an important component of eliciting behaviour change
- behaviour is a result of three factors
  1. predisposing factors: knowledge, attitude, beliefs, values, intentions
  2. enabling factors: skills, supports
  3. reinforcing factors: health care professionals and the social context of family and community

Health Belief Model (1975)

- “behaviours undertaken by individuals in order to remain healthy […] are a function of a set of interacting beliefs”
- beliefs include: (i) individual’s perception of their susceptibility to a disease; (ii) severity of the disease; (iii) efficacy of proposed change/action; (iv) benefits and costs of health-related actions
- beliefs are modified by socio-demographic and psychosocial variables
- individuals must be in a state of readiness
- behaviour can be stimulated by cues to action, which are triggers that can encourage preventive health decisions and actions (e.g. physician recommendation, public advertising)

Stages of Change Model

- provides a framework in which the Health Belief Model is applied to facilitating behaviour change (e.g. quitting smoking)

Figure 3. Stages of change model

Risk Reduction Strategies

- risk reduction: lower the risk to health without eliminating it (e.g. avoiding sun to lower risk of skin cancer)
- harm reduction: tolerance of some degree of risk behaviour, while aiming to minimize the adverse outcomes associated with these behaviours (e.g. needle exchange programs)

Measurements of Health and Disease in a Population

Incidence Rate

- number of new cases in a population per unit of person-time

Prevalence

- total number of cases in a population over a defined period of time
- two forms of prevalence
  - point prevalence: assessed at one point in time
  - period prevalence: as above, but all cases over defined time window (including ‘incident’ ones) are included:
    - depends on incidence rate and disease duration from onset to termination (cure or death)
    - favours the inclusion of chronic over acute cases and may underestimate disease burden if those with short disease duration are missed
- prevalence studies are cross-sectional and provide weak evidence for causal inferences
- prevalence figures are useful for determining the extent of a disease and can aid in the planning of facilities and services

Example of Harm Reduction Strategy – Evaluation of a Pilot Medically Supervised Safer Injection Facility

CMAJ 2006;175:1399-1404

Purposes: To evaluate the outcomes of a supervised safer injecting facility facilitating pre-obtaining illicit drugs under supervision of medical staff, conducted over a 2 year period.

Methods: IDUs who used the safer injecting facility included age <30 yr, history of drug use, homelessness, daily heroin and/or cocaine injection, and recent history of overdose. This has resulted in lower incidences of public drug use, publicly discarded syringes and sharing of needles. Other studies associated with this one have demonstrated that there has been no increase in the drug dealing, drug related crimes, or rates of new IDUs in the area surrounding the safer injecting facility.

Incidence and Prevalence

Incidence = # of new cases in a time interval

Prevalence = # of existing cases at a point in time

e.g. For Canada in 2011:

HIV incidence rate is 9.5 per 100,000 people
HIV prevalence is 213 per 100,000 people

Top 5 Causes of Mortality in Canada, 2012, by Sex

Female
- Cancer
- Heart disease
- Stroke
- COPD/chronic lower respiratory disease
- Alzheimer’s

Male
- Cancer
- Heart disease
- Accidents
- Stroke
- COPD/chronic lower respiratory disease

Age Standardized Rate
• adjustment of the crude rate of a health-related event using a “standard” population
• standard population is one with a known number of persons in each age and sex group
• standardization prevents bias which could be made by comparing crude rates from two dissimilar populations (e.g. crude death rates over a number of decades are not comparable as the population age distribution has changed with time)

MEASURES OF MORTALITY

Life Expectancy
• “the expected number of years to be lived by a newborn based on age-specific mortality rates at a selected time”
• usually qualified by country, gender, and age

Crude Death Rate
• mortality from all causes of death per 1,000 in the population

Infant Mortality Rate (IMR)
• number of deaths among children >1 yr of age reported during a given time period divided by the number of live births reported during the same time period and expressed per 1000 live births per year

Maternal Mortality Rate (MMR)
• “number of deaths of women during pregnancy and due to puerperal causes […] per 1000 live births in the same year”

MEASURES OF DISEASE BURDEN

Potential Years of Life Lost (PYLL)
• calculated for a population using the difference between the actual age at death and a standard/expected age at death
• increased weighting of mortality at a younger age

Disability Adjusted Life Year (DALY)
• life expectancy weighted by amount of disability experienced
• both premature death and time spent with disability accounted for; these disabilities can be physical or mental

Quality Adjusted Life Year (QALY)
• years of life weighted by utility (similar to quality of life), ranging from 0-1 assigned to a year of life based on perceived quality of life; a yr in “perfect” health is considered equal to 1 QALY, the value of a year in ill health would be lowered based on the burden of disease
• it is possible to have “states worse than death” for example QALY <0 for extremely serious conditions

For additional rate calculations see Outbreak of Infectious Diseases, PH19
Consult the Public Health Agency of Canada for examples and latest statistics

Sources: Shah, CP. Health Indicators and Data Sources. Public Health and Preventive Medicine in Canada, 5e. Toronto: Elsevier, 2003

Epidemiology

Population
• a defined collection of individuals/regions/institutions/etc (e.g. individuals defined by geographic region, sex, age)

Sample
• a selection of individuals from a population
• types
  • random: all members are equally likely to be selected
  • systematic: an algorithm is used to select a subset
  • stratified: population is divided into subgroups that are each sampled
  • cluster: grouped in space/time to reduce costs
  • convenience: non-random inclusion, usually volunteers

Sample Size
• sample size contributes to the statistical precision of the observed estimate
• increasing the sample size decreases the probability of type I and type II errors
• increasing sample size does not reduce bias/confounding
Bias
- systematic error causing results to differ from correct values/inferences
- can occur at any point in study execution (e.g. collection, analysis, interpretation, publication, or review of data)
  - sampling bias: occurs with the selection of a sample that does not truly represent the population
  - sampling procedures should be chosen to prevent or minimize bias
  - measurement bias: systematic error arising from inaccurate measurements of subjects
  - recall bias: bias in individuals’ responses when reporting on past exposures/events
    - e.g. individuals with disease may be more likely to incorrectly recall/believe they were exposed to a possible risk factor than those who are free of disease

Confounder
- a variable that is related to both the exposure and outcome but is not a mediator in the exposure-outcome relationship
- distorts the estimated effect of an exposure if not accounted for in the study design/analysis (e.g. late maternal age could be a confounder in an investigation of birth order >4 and risk of developing Trisomy 21)
- randomization, stratification, matching, and regression modelling can help minimize confounder effects

Interpreting Test Results

<table>
<thead>
<tr>
<th></th>
<th>TP = True positive</th>
<th>TN = True negative</th>
<th>FP = False positive</th>
<th>FN = False negative</th>
</tr>
</thead>
<tbody>
<tr>
<td>Test Result</td>
<td>Positive</td>
<td>Sensitivity = TP/(TP+FN)</td>
<td>Specificity = TN/(TN+FP)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Negative</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Likelihood Ratio (LR)
- Likelihood that a given test result would be expected in a patient with disease compared with the likelihood that the same result would be expected in a patient without disease
- LR+ indicates how much the probability of disease increases if the test is positive
- LR- indicates how much the probability of disease decreases if the test is negative

Positive Predictive Value (PPV)
- Proportion of people with a positive test who have the disease

Negative Predictive Value (NPV)
- Proportion of people with a negative test who are free of disease

Advanced Neoplasia

<table>
<thead>
<tr>
<th>Test Result</th>
<th>Present</th>
<th>Negative</th>
</tr>
</thead>
<tbody>
<tr>
<td>Positive</td>
<td>68</td>
<td>147</td>
</tr>
<tr>
<td>Negative</td>
<td>216</td>
<td>2234</td>
</tr>
<tr>
<td>Total</td>
<td>284</td>
<td>2381</td>
</tr>
</tbody>
</table>

Sensitivity = 68/284 = 23.9%
Specificity = 2234/2381 = 93.8%

LR+ = Sensitivity = 0.239
LR- = 1 - Sensitivity = 0.761
PPV = 68/(68+147) = 31.6%
NPV = 2234/(2234+216) = 91.2%

Figure 4. Understanding sensitivity and specificity

SPIN: use a Sspecific test to rule IN a hypothesis. Note that specific tests have very few false positives. If you get a positive test, it is likely a true positive

SNOUT: use a SENitive test to rule OUT a hypothesis. Note that sensitive tests have very few false negatives. If you get a negative test, it is likely a true negative

Sensitivity
- proportion of people with disease who have a positive test

Specificity
- proportion of people without disease who have a negative test

Pre-Test Probability
- the probability a particular patient has a given disease before a test/assessment results are known
Post-Test Probability
- a revision of the probability of disease after a patient has been interviewed/examined/tested
- calculation process can be explicit using results from epidemiologic studies, knowledge of the accuracy of tests, and a nomogram/Bayes' theorem
- the post-test probability from clinical examination is the basis of consideration when ordering diagnostic tests or imaging studies
- after each iteration the resultant post-test probability becomes the pre-test probability when considering new investigations

Effectiveness of Interventions
Effectiveness, Efficacy, Efficiency
- three measurements indicating the relative value (beneficial effects vs. harmful effects) of an intervention
  - **efficacy**: the extent to which a specific intervention produces a beneficial result under ideal conditions (e.g. RCT)
    - ideal conditions include adherence, close monitoring, access to health resources, etc.
  - **effectiveness**: measures the benefit of an intervention under usual conditions of clinical care
    - considers both the efficacy of an intervention and its actual impact on the real world, taking into account access to the intervention, whether it is offered to those who can benefit from it its proper administration, acceptance of intervention, and degree of adherence to intervention
  - **efficiency**: a measure of economy of an intervention with known effectiveness
    - considers the optimal use of resources (e.g. money, time, personnel, equipment, etc.)

<table>
<thead>
<tr>
<th>Disease (e.g. lung CA)</th>
<th>Present</th>
<th>Absent</th>
<th>Total</th>

</tr>
</tbody>
</table>

**Case-Control Study**

\[
\text{odds ratio (OR)}^* = \frac{A}{C} = \frac{B}{D} = \frac{A \times D}{B \times C}
\]

**Cohort Study**

\[
\frac{A}{A + B} = \text{incidence rate of health outcome in exposed} \quad \frac{C}{C + D} = \text{incidence rate of health outcome in non-exposed}
\]

relative risk (RR)** = \frac{A}{A + B} - \frac{C}{C + D} 

attributable risk (AR)** = \frac{A}{A + B} - \frac{C}{C + D}

*Ratio of the odds in favour of the health outcome among the exposed to the odds in favour among the unexposed
**Ratio of the risk of a health outcome among exposed to the risk among the unexposed
***Ratio of health outcome in exposed individuals that can be attributed to the exposure

**Number Needed to Treat (NNT)**
- number of patients who need to be treated to achieve one additional favourable outcome
- only one of many factors that should be taken into account in clinical or health system decision making (e.g. must take into account cost, ease, feasibility of intervention)
- a condition with death as a potential outcome can have a higher NNT (and be acceptable), as compared to an intervention to prevent an outcome with low morbidity, in which a low NNT would be necessary

**Number Needed to Harm (NNH)**
- number of patients who, if they received the experimental treatment, would lead to one additional patient being harmed, compared with patients who received the control treatment

**Adherence (formerly compliance)**
- degree to which a patient follows a treatment plan

**Coverage**
- extent to which the services rendered cover the potential need for these services in a community

Sources: Shah, CP. Health Indicators and Data Sources. Public Health and Preventive Medicine in Canada. 5e. Toronto: Brever, 2003

Equations to Assess Effectiveness

\[
\begin{align*}
\text{CER} & = \text{control group event rate} \\
\text{EER} & = \text{experimental group event rate} \\
\text{RR} & = \frac{\text{EER}}{\text{CER}} \\
\text{ARR} & = \text{CER} - \text{EER} \\
\text{NNT} & = \frac{1}{\text{ARR}} \\
\end{align*}
\]

### Quantitative Research Methods

![Figure 8. Quantitative study designs](http://phprimer.afmc.ca)

**Formulating a Research Question**

**PICO**
- **Population/Patient Characteristics**
- **Intervention/Exposure of Interest**
- **Comparison Group or Control Group**
- **Outcome that you are trying to prevent or achieve**

### Observational Study Designs

- observational studies involve neither the manipulation of the exposure of interest nor randomization of the study subjects
- there are two main subtypes of observational studies: descriptive and analytic studies

#### Descriptive Studies
- describe the events and rates of disease with respect to person, place and time; estimates disease frequency and time trends
- can be used to generate an etiologic hypothesis and for policy planning

#### Analytic Studies
- observational studies used to test a specific hypothesis
- includes ecological studies, cohort studies, case-control studies, and cross-sectional studies

An example of an ecological fallacy would be concluding that red wine drinking leads to lower risk of death from CVS disease after an ecological study shows that countries with a higher rate of red wine consumption have a lower rate of death from CVS causes.
Table 7. Observational Study Designs

<table>
<thead>
<tr>
<th>Type of Study</th>
<th>Ecological</th>
<th>Cross-Sectional</th>
<th>Case Control</th>
<th>Cohort</th>
</tr>
</thead>
<tbody>
<tr>
<td>Definition</td>
<td>Units of analysis are populations or groups of people, rather than individuals</td>
<td>Use individual data on exposures and outcomes gathered at the same time</td>
<td>Samples a group of people who already have a particular outcome (cases) and compares them to a similar sample group without that outcome (controls)</td>
<td>Subjects are sampled and, as a group, classified on the basis of presence or absence of exposure to a particular risk factor</td>
</tr>
<tr>
<td>Subjects</td>
<td>Aggregated groups (e.g. cities)</td>
<td>Sample of a population</td>
<td>Two or more samples of individuals with and without the outcome(s) of interest (i.e. cases and controls)</td>
<td>One or more cohorts Cohort: group of people with common characteristics (e.g. year of birth, region of residence) Divided into measured exposed vs. non-exposed groups</td>
</tr>
<tr>
<td>Methods</td>
<td>Descriptions of the average exposure or risk of disease for a population Can use regression models to test associations between area-level predictors and aggregate outcomes Collect information from each person at one particular time Tabulate the numbers in groups (e.g. by presence or absence of disease/factor of interest) Make tables and compare groups Estimate prevalence Use regression models to test associations between predictors and outcomes of interest Select sample of cases of a specific disease during a specific time frame Representative of spectrum of clinical disease Select control(s) Represent the general population To minimize risk of bias, may select more than one control group and/or match controls to cases (e.g. age, gender) Assess past exposures (e.g. EMR, questionnaires) Association can be concluded between the risk factor and the disease (odds ratio) Collect information on factors from all persons at the beginning of the study Subjects are followed for a specific period of time to determine development of disease in each exposure group Prospective: measuring from the exposure at present to the future outcomes Retrospective: measuring forward in time from exposures in the past to later outcomes Use statistical models to test associations between exposures and disease or other measured outcomes Provides estimates of incidence, relative risk, attributable risk</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Advantages</td>
<td>Quick, easy to do Uses readily available data Generates hypothesis Determines association between variables Quick and uses fewer resources Surveys with validated questions allows comparison between studies Often used when disease in population is rare (less than 10% of population) due to increased efficiency or when time to develop disease is long Less costly and time consuming Shows an association between risk factor(s) and outcome(s) Stronger evidence for causation Can consider a variety of exposures and outcomes</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Disadvantages</td>
<td>Poor generalizability to individual level (not direct assessment of causal relationship) Ecological fallacy: an incorrect inference from groups to individuals Confounding Does not allow for assessment of temporal relationship or offer strong evidence for causation between variables Recall bias (see Bias, PH9) Confounding Selection bias for cases and controls Only one outcome can be measured Confounding may occur due to individuals self-selecting the exposure, or unknown/unmeasured factors are associated with the measured exposure and outcome Cost and duration of time needed to follow cohort Selection bias</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Examples</td>
<td>A study looking at the association between smoking rates and lung cancer rates in different countries at the population level without individual data on both factors A study that examines the distribution of BMI by age in Ontario at a particular point in time A famous case control study published by Sir Richard Doll demonstrated the link between tobacco smoking exposure and lung cancer cases at the individual level A famous cohort study is the Framingham Heart Study, which assessed the long-term cardiovascular risks of diet, exercise, medications such as ASA, etc.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Experimental Study Designs

not discussed here are non-randomized control trials (e.g. allocation by clinic or other non-random basis – performed when randomization is not possible)

RANDOMIZED CONTROLLED TRIAL (RCT)

Definition
- subjects are assigned by random allocation to two or more groups, one of which is the control group, the other group(s) receive(s) an intervention

Subjects
- individuals are selected using explicit inclusion/exclusion criteria with recruitment targets guided by sample size calculations

Methods
- random allocation of individuals into two or more treatment groups through a centralized concealed process
- method of assessment to reduce bias
  - single-blind: subject does not know group assignment (intervention or placebo)
  - double-blind: subject and observer both unaware of group assignment
  - triple-blind: subject, observer, and analyst unaware of group assignment
- one group receives placebo or standard therapy
- one or more groups receive(s) the intervention(s) under study
- baseline covariates and outcome(s) are measured and the groups are compared
- all other conditions are kept the same between groups

Advantages
- “gold standard” of studies, upon which the practice of EBM is founded
- provides the strongest evidence for effectiveness of intervention
- threats to validity are minimized with sufficient sample size and appropriate randomization
- randomization is one of few methods that can address selection bias and confounding (including unmeasured confounders)
- allows prospective assessment of the effects of intervention

Disadvantages
- some exposures are not amenable to randomization (e.g. cannot randomize subjects to poverty/wealth or to harmful exposures such as smoking) due to ethical or feasibility concerns
- can be difficult to randomly allocate groups (e.g. communities, neighbourhoods)
- difficult to study rare events, since RCTs would require extremely large sample sizes
- contamination, co-intervention, and loss to follow-up can all limit causal inferences
- can have poor generalizability
- costly

Summary Study Designs

META-ANALYSIS

Definition
- a form of statistical analysis that synthesizes the results of independent studies addressing a common research question, as identified through systematic review

Subjects
- all the studies identified through the review (or all subjects used in original studies for individual level meta-analysis)

Methods
- selection of relevant studies from the published literature which meet quality criteria
- statistical models used to combine the results of each independent study
- provides a summary statistic of overall results as well as graphic representation of included studies (forest plot)

Advantages
- attempts to overcome the problem of reduced power due to small sample sizes of individual studies
- ability to control for inter-study variation
- can address questions (e.g. subgroup analyses) that the original studies were not powered to answer

Analysis
- Per-Protocol Analysis (PP): Strategy of analysis in which only patients who complete the entire study are counted towards the results

Intention-to-Treat Analysis (ITT)
- When groups are analyzed exactly as they existed upon randomization (i.e. using data from all patients, including those who did not complete the study)

An example of a meta-analysis is one that compares the effects of ACE inhibitors, CCBs, and other antihypertensive agents on mortality and major cardiovascular events by compiling and analyzing data from a full set of reported RCTs
Methods of Analysis

Distributions

- distribution describes the probability of events
- normal (Gaussian) or non-normal (binomial, gamma, skewed, etc.)
- characteristics of the normal distribution
  - mean = median = mode
  - 67% of observations fall within one standard deviation of the mean
  - 95% of observations fall within two standard deviations of the mean
- measures of central tendency
  - mean: sum of each observations' data (e.g. ages) divided by total number of observations
  - median: value of the 50th percentile; a better reflection of the central tendency for a skewed distribution
  - mode: most frequently observed value in a series
- measures of dispersion
  - range: the largest value minus the smallest value
  - variance: a measure of the spread of data
  - standard deviation: the average distance of data points from the mean (the positive square root of variance)
- given the mean and standard deviation of a normal or binomial distribution curve, a description of the entire distribution of data is obtained

Data Analysis

Statistical Hypotheses

- null (H0): the default hypothesis; often states there is no relationship between two variables
- alternative (H1): the hypothesis that we are interested in; often states there is a relationship between two variables
  - we can find evidence against H0 but we can never 'prove' H1

Type I Error (α Error)

- the null hypothesis is falsely rejected (i.e. concluding an intervention X is effective when it is not, or declaring an observed difference to be real rather than by chance)
- the probability of this error is denoted by the p-value
- studies tend to be designed to minimize this type of error, since a type I error can have larger clinical significance than a type II error

Type II Error (β Error)

- the null hypothesis is falsely accepted (i.e. stating intervention X is not effective when it is, or declaring an observed difference/effect to have occurred by chance when it is present)
- by convention a higher level of error is often accepted for most studies
- can also be used to calculate statistical power

Power

- probability of correctly rejecting a null hypothesis when it is in fact false (i.e. the probability of finding a specified difference to be statistically significant at a given p-value)
- power increases with an increase in sample size
- power = 1 – β, and is therefore equal to the probability of a true positive result

Statistical Significance

- the probability that the statistical association found between variables is due to random chance alone (i.e. there is no association)
- the preset probability is set sufficiently low that one would act on the result; frequently p<0.05
- when statistical tests result in a probability less than the preset limit, the results are said to be statistically significant (denoted by the α-value)

Disadvantages

- sources of bias may not be controlled for
- reliance on published studies may increase the potential conclusion of an effect as it can be difficult to publish studies that show no significant results (publication bias)
- the decision to include/reject a particular study is subjective

Sources:

Example Calculation

Data set: 17, 14, 17, 10, 7
Mean = (17 + 14 + 17 + 10 + 7) ÷ 5 = 13
Median (write the list in order, median is the number in the middle) = 7, 10, 14, 17 = 14
Mode (number repeated more often) = 17
Range = 17 – 7 = 10
Variance = [(17 – 13)² + (14 – 13)² + (17 – 13)² + (10 – 13)² + (7 – 13)²] ÷ 4 = 19.5
Standard Deviation = √variance = √19.5 = 4.42

Type I (α) Error

"There Is An Effect" where in reality there is none

Consult the Cochrane Library of Systematic Reviews (http://www.cochranelibrary.com) for high-quality systematic reviews and meta-analyses
Clinical Significance
- measure of clinical usefulness (e.g. 1 mmHg BP reduction may be statistically significant, but may not be clinically significant)
- depends on factors such as cost, availability, patient compliance, and side effects in addition to statistical significance

Confidence Interval (CI)
- provides a range of values within which the true population result (e.g. the mean) lies
- frequently reported as 95% CI (i.e. 95% chance that the true value is within this data range)
- bounded by the upper and lower confidence limits

Data
- information collected from a sample of a population
- there are 4 overall levels of measurement for quantitative data
  - categorical (e.g. blood type, marital status)
  - ordinal (e.g. low, medium, high)
  - interval (e.g. °C, time of day)
  - ratio (e.g. serum cholesterol, hemoglobin, age)

Validity/Accuracy (of a measurement tool)
- how closely a measurement reflects the entity it claims to measure

Reliability/Precision
- how consistent multiple measurements are when the underlying subject of measurement has not changed
- may be assessed by different observers at the same time (inter-rater reliability) or by the same observer under different conditions (test-retest reliability)

Internal Validity
- degree to which the findings of the sample truly represent the findings in the study population
- dependent on the reliability, accuracy, and absence of other biases

External Validity (i.e. Generalizability)
- degree to which the results of the study can be generalized to other situations or populations

Common Statistical Tests

<table>
<thead>
<tr>
<th>Table 8. Statistical Tests</th>
<th>Two-sample t-Test</th>
<th>Analysis of Variance (ANOVA)</th>
<th>Chi-Squared Test ($\chi^2$)</th>
<th>Linear Regression</th>
<th>Logistic Regression</th>
<th>Pearson product-moment correlation (Pearson’s r)</th>
</tr>
</thead>
<tbody>
<tr>
<td>What are you trying to show?</td>
<td>Compare the mean values of an outcome variable between two groups (e.g. difference in average BP between men and women)</td>
<td>Compare the mean values of an outcome variable between two or more groups (e.g. difference in average BP between persons in three towns)</td>
<td>Test the correspondence between a theoretical frequency distribution and an observed frequency distribution (e.g. if one sample of 20 patients is 30% hypertensive and another comparison group of 25 patients is 60% hypertensive, a chi-squared test determines if this variation is more than expected due to chance alone)</td>
<td>Looks at associations between two or more variables (e.g. age and blood pressure)</td>
<td>Shows how a change in one explanatory variable affects the status (e.g. if vs. non-ill) of the outcome variable</td>
<td>Assesses the strength of the linear relationship between two variables. Ranges from -1 (negative association, i.e. increases in one variable are associated with decreases in another) to 1 (positive association, increases in one variable are associated with increases in the other). A correlation of 0 indicates no relationship</td>
</tr>
</tbody>
</table>

What kind of variables do you measure?

<table>

</tr>
</tbody>
</table>

Assumptions

| Data follow a normal distribution | Equal variances | Data are independent | The Normal distribution of dependent variable’s error term | Expected counts must be at least 5 for all cells in n by m table | Data are independent | Dependent variable’s error term has a normal distribution | Linear relationship between variables | Homoskedasticity | No influential values | Data are independent | Underlying relationship is linear | Data for both variables are Normally distributed | Data are independent |

Good reliability
- Good accuracy
- Poor reliability
- Good accuracy

Figure 12. Validity vs. reliability

What’s the difference between Pearson and Spearman correlation?
Different types of correlation are used for different levels of measurement. Pearson is for continuous and Normal data, Spearman is for ordinal or non-Normal data. There are other forms of correlation for other levels of measurement (e.g. Tetrachoric/polychoric)
Causation

Criteria for Causation (Sir Bradford Hill)
1. strength of association: the frequency with which the factor is found in the disease, and the frequency with which it occurs in the absence of disease
2. consistency: is the same relationship seen with different populations or study design?
3. specificity: is the association particular to your intervention and measured outcome?
4. temporal relationship: did the exposure occur before the onset of the disease?
5. biological gradient: finding a dose response relationship between the exposure-outcome
6. biological plausibility: does the association/causation make biological sense?
7. coherence: can the relationship be explained/accounted for based on what we know about science, logic, etc.?
8. experimental evidence: does experimental evidence support the association (e.g. is there improvement?)
9. analogy: do other established associations provide a model for this type of the relationship?

Note: Not all criteria must be fulfilled to establish scientific causation, and the modern practice of EBM emphasizes ‘experimental evidence’ as superior to other criteria for experimental causation review. However, many causation questions in health cannot be answered with experimental methods.

Assessing Evidence

• critical appraisal is the process of systematically examining research evidence to assess validity, results, and relevance before using it to inform a decision

Figure 13. Pyramid of pre-appraised evidence

Validity
• The degree to which the outcome observed in the study can be attributed to the intervention

5 Questions About the Validity of Primary Studies
• Were the patients randomized?
• Were the follow-up of patients sufficiently long and complete?
• Were all patients analyzed in the groups to which they were randomized?
• Were the groups treated equally except for the intervention?
• Were the patients and clinicians kept blind to treatment?

Other Questions to Consider
• Were the groups similar (i.e. demographics, prognostic factors) at the start of the trial?
• Were the appropriate and valid exposure and outcome measures obtained?
• Were outcome assessors aware of group allocation?
• Was contamination reported?
• Were ethical issues continuously upheld?

Levels of Evidence Classifications Cited in Guidelines/Consensus Statements

<table>
<thead>
<tr>
<th>Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>Based on RCTs (or meta-analysis of RCTs) big enough to have low risk of incorporating FP or FN results.</td>
</tr>
<tr>
<td>II</td>
<td>Based on RCTs too small to provide Level I evidence; may show positive trends that are non-significant, or have a high risk of FN results.</td>
</tr>
<tr>
<td>III</td>
<td>Based on non-randomized, controlled or cohort studies; case series; case-controlled; or cross-sectional studies.</td>
</tr>
<tr>
<td>IV</td>
<td>Based on opinion of respected authorities or expert committees, as published consensus conferences/guidelines.</td>
</tr>
<tr>
<td>V</td>
<td>Opinions of the authors who have written/reviewed the guidelines.</td>
</tr>
</tbody>
</table>

Notes: These 5 levels of evidence are not direct evaluations of evidence quality or credibility; they reflect the nature of the evidence. While RCTs tend to be most credible (with <III), level III evidence gains credibility when multiple studies from different locations and/or time periods report consistent findings. Level IV and V evidence reflects decision-making that is necessary but in the absence of published evidence.

Figure 14. Levels of evidence classifications

Note: This is only one method of classifying evidence. Various systems exist, but operate within the same premise that certain types of evidence carry more weight than others.

Health Services Research

Continuous Quality Improvement

Quality Improvement (QI)
- A means of evaluating and improving processes; focusing more on systems and systematic biases, which are thought to cause variation in quality.
- Measures to increase efficiency of action with the purpose of achieving optimal quality.

Quality Assurance
- Process to guarantee the quality of health care through improvement and attainment of set standards.
- “Five-stage process of quality assurance” (Public Health and Preventative Medicine in Canada, Shah)
  1. Formulation of working goals
  2. Procedural changes to implement those goals
  3. Regular comparison of current performance with original goals
  4. Development of solutions to bring performance closer to goals
  5. Documentation of quality assurance activities

Quality Control
- A process of analyzing the quality of all factors involved in the process to maintain standards.

Continuous Quality Improvement
- The process of ongoing service/product refinement via the vigilant review of expectant issue detrimental to the system and regular incorporation of improvements.

Quality Management
- Combination of several processes (assurance, control, improvement) to maintain consistent quality.

Total Quality Management
- Management principle for advancing quality while minimizing additional expenditures.
- Focuses on the entire system rather than discrete elements.

Audit
- Methodical analysis of a quality system by quality auditor.
- To determine whether quality processes and results comply with goals, and whether processes have been implemented effectively.

Systems Analyses Tools
1. 5 Whys: Brainstorming to simplify the process of change; continue asking ‘why’ until the root of the problem is discovered.
2. Ishikawa Diagrams (i.e. Fishbone Diagrams): Identify generic categories of problems that have an overall contribution on the effect.
3. Defect check sheets: Consider all defects and tally up the number of times the defect occurs.
4. Pareto Chart: X vs. Y chart; x-axis = defect categories, y-axis = frequency; plot cumulative frequency on the right y-axis; purpose is to highlight most important among large set of factors contributing to defects/poor quality.
Outbreak of Infectious Diseases

**Precede-Proceed Model**
- tool for designing, implementing, and evaluating health interventions/programs

**Table 9. Precede-Proceed Model**

<table>
<thead>
<tr>
<th>PRECEDE Phase</th>
<th>PROCEED Phase</th>
</tr>
</thead>
<tbody>
<tr>
<td>Phase 1 – Identify the ultimate desired result</td>
<td>Phase 5 – Implementation (design and conduct the intervention)</td>
</tr>
<tr>
<td>Phase 2 – Identify health issues and their behavioural and environmental determinants. Set priorities among them</td>
<td>Phase 6 – Process Evaluation (determine if the program is implemented as planned)</td>
</tr>
<tr>
<td>Phase 3 – Identify the predisposing, enabling, and reinforcing factors that affect the behaviours and environmental determinants</td>
<td>Phase 7 – Impact Evaluation (measure intermediate objectives – predisposing, enabling, and reinforcing factors)</td>
</tr>
<tr>
<td>Phase 4 – Identify the administrat ve and policy factors that influence what can be implemented</td>
<td>Phase 8 – Outcome Evaluation (measure desired result)</td>
</tr>
</tbody>
</table>

**Cost Analysis**

**Cost Benefit Analysis (CBA)**
- an analysis which compares the total expected costs with the total expected benefits of actions in order to choose the most profitable or beneficial options
- costs are controlled for inflation and market changes so that the effect of the change is evaluated over a consistent, preset financial value

**Cost Effectiveness Analysis (CEA)**
- ratio of the change in cost (numerator) to change in effect (denominator) in response to a new strategy or practice
  - some examples of changes in effect (denominator) could be years of life gained or sight-years gained
  - the numerator highlights the cost of the health gain
  - the most commonly used outcome measure is quality-adjusted life years (QALY) (see *Quality Adjusted Life Year, PH8*)
- can be used where an extensive cost benefit analysis is not applicable or appropriate

**Outbreak of Infectious Diseases**

**Definitions**

**Endemic**
- consistent existence of infectious agent or disease in a given population or area (i.e. usual rate of disease)

**Outbreak**
- incidence of new cases beyond the usual frequency of disease in a particular population or community over a given period of time
- an epidemic that is in a confined location, has a short duration, or begins acutely

**Epidemic**
- an outbreak or excessive rate of disease that rapidly spreads to a large number of individuals (e.g. SARS epidemic)

**Pandemic**
- epidemic over a wide area, crossing international boundaries, and affecting an even larger number of people
Attack Rate
- cumulative incidence of infection within a defined group observed during a specific period of time in an epidemic
- calculated by dividing the total number of people who develop clinical disease by the population at risk, usually expressed as a percentage

Secondary Attack Rate
- the proportion of individuals who develop disease as a result of exposure to primary contacts during the incubation period
- infectiousness reflects the ease of disease transmission and is usually measured by the secondary attack rate

Virulence
- extent of sickness caused in host by a disease-causing agent
- ratio comparing those with the disease who are critically affected over the total number of individuals in the population who have the disease

Case-Fatality Rate (CFR)
- proportion of individuals with the disease who perish as a result of the illness
- most frequently applied to a specific outbreak of acute disease in which all patients have been followed for an adequate period of time to include all attributable deaths
- must be clearly differentiated from the mortality rate

Mortality Rate/Crude Death Rate
- estimation of the portion of the population that dies during a specified period from all causes of death

Steps to Control an Outbreak

Adopted from AFMC Primer on Population Health

1. Determine whether an outbreak

2. Develop case definitions and identify outbreak cases
- consider history, signs, symptoms, test results, and timing to balance sensitivity and specificity in case definition
- consider engaging in active surveillance to identify additional cases

3. Develop hypotheses regarding outbreak cause/source and implement initial control measures
- identify source, population at risk
- manage cases, including appropriate isolation
- reinforce importance of routine and additional precautions

4. Test hypotheses using surveillance data or special studies
- describe cases by person, place, and time to create a line listing
- plot an epidemic curve:
  - histogram with time on the x-axis and number of cases on the y-axis
  - often follows a characteristic pattern based on the nature of the exposure and/or infectious agent:
    - point source epidemic: exposure is brief and not continuous or propagated (e.g. single contaminated dish at a picnic)
    - extended source epidemic: exposure may be continuous (or intermittent if peaks are irregular) and lasts for days or weeks (e.g. ongoing or intermittent contamination of drinking water)
    - propagated epidemic: series of peaks demonstrating only a few cases initially, but then ongoing person-to-person transmission (e.g. influenza virus)

5. Re-evaluate hypothesis and adjust control measures

6. Create and implement plans for future prevention and control
- examples include prevention of transmission in the environment (e.g. handwashing and sterilization techniques), immunization of hosts, and education of healthcare professionals and the public

Active Surveillance
- Outreach such as visits or phone calls by the public health/surveillance authority to detect unreported cases (e.g. an infection control nurse goes to the ward and reviews temperature charts to see if any patient has a nosocomial infection)

Passive Surveillance
- A surveillance system where the public health/surveillance authority depends on others to submit standardized forms or other means of reporting cases (e.g. ward staff notify infection control when new cases of nosocomial infections are discovered)
Environmental Health

Definition
- study of the association between environmental factors, both constructed and natural, and health
- environmental exposures
  - four common hazards: chemical, biological, physical, and radiation
  - four main reservoirs: air, food, water, and soil
  - three main routes: inhalation, ingestion, or absorption (skin)
  - usually divided into two main settings:
    - workplace (including schools): may see high level exposure in healthy individuals (see Occupational Health, PH23)
    - non-workplace: lower levels of exposure over longer period of time. Affects vulnerable populations more severely, such as at extremes of age, immuno-suppressed. May be teratogenic
- health impacts of the environment also include factors such as urban planning and how individuals interact with the built environment (e.g. safe pedestrian and bicycle paths can facilitate more active lifestyles)

Risk Assessment

Adapted from p.250 Sixth Edition of "A Dictionary of Epidemiology" by Miquel Porta

Hazard Identification
- what is the hazard involved?
- assess potential hazards by taking environmental health history

Risk Characterization
- is the identified agent likely to elicit the patient’s current symptoms?
- review known health impacts of the hazard and identify specific properties that contribute to or diminish adverse effects (e.g. evaluate threshold levels)

Exposure Assessment
- is the patient’s exposure to the environmental agent sufficient to have caused the current symptoms?
- quantify exposure through direct measurement or by reviewing frequency and nature of contact with hazard

Air

Biological Hazards
- moulds thrive in moist areas; 10-15% of the population allergic
- bacteria survive as spores and aerosols, can be distributed through ventilation systems (e.g. Legionella)
- dust mites (year-round) and pollens (seasonal) can trigger upper and lower-airway symptoms

Chemical Hazards
- ground-level ozone
  - main component of smog with levels increasing in major cities
  - worsens asthma, irritates upper airway
- carbon monoxide (fossil fuel related, common byproduct of combustion)
  - aggravates cardiac disease at low levels
  - headache, nausea, dizziness at moderate levels
  - fatal at high levels
- sulphur dioxide (fossil fuel-related), nitrogen oxides
  - contribute to acid rain and exacerbate breathing difficulties
- organic compounds at high levels (e.g. benzene, methylene chloride, tetrachloroethylene)
  - tend to be fat-soluble, easily absorbed through skin and difficult to excrete
- heavy metal emissions (e.g. nickel, cadmium, chromium)
  - variety of health effects: upper airway disease, asthma, decreased lung function
  - second-hand tobacco smoke
    - respiratory problems, increase risk of lung cancer
  - particulates associated with decreased lung function, asthma, upper airway irritation

Radiation Hazards
- sound waves
  - ionizing radiation
  - radon is naturally produced by soil containing uranium or radium, can contaminate indoor air and is associated with a small proportion of lung cancers
- ultraviolet radiation is increasing due to ozone layer destruction and increases risk of skin cancer
  - non-ionizing radiation
  - visible light, infrared, microwave

Water

Biological Hazards
- mostly due to human and animal waste
  - Aboriginal Canadians, rural Canadians at higher risk
  - bacteria: Escherichia coli (e.g. Walkerton, ON), Salmonella, Pseudomonas, Shigella
  - protozoa: Giardia, Cryptosporidium (e.g. North Battleford, SK)

Chemical/Industrial Hazards
- chlorination by-products (e.g. chloroform can cause cancer at high levels)
- volatile organic compounds, heavy metals, pesticides, and other industrial waste products can be present in groundwater
- fluoride at high levels (greater than that of municipal fluoridation) can cause skeletal fluorosis

BPA, The Toxic Concern of 2009
Bisphenol A (BPA) is a chemical compound found in some hard, clear, lightweight plastics and resins. According to the NIH, animal studies suggest that ingested BPA may mimic estrogen and other hormones. In October 2008, Canada became the first country in the world to ban the import and sale of polycarbonate baby bottles containing BPA, stating that although exposure levels are below levels that cause negative effects, current safety margins need to be higher. The US FDA does not consider normal exposure to BPA to be a hazard, however the NIH has some concern that fetuses, infants, and children exposed to BPA may be at increased risk for early-onset puberty, prostate, and breast cancer.

Particulate Matter Air Pollution and Cardiovascular Disease: An Update to the Scientific Statement from the American Heart Association
Circulation 2010 Jun 1;121(21):2331-78
A scientific statement by the American Heart Association in 2004 reported that exposure to particulate matter air pollution contributes to cardiovascular morbidity and mortality. An updated American Heart Association statement in 2010 confirmed a causal relationship between particulate matter exposure and cardiovascular morbidity and mortality. The statement reported that such an exposure over several hours to weeks may trigger cardiovascular disease-related mortality and non-fatal events, whereas longer exposures over several years may further increase cardiovascular mortality and reduce life expectancy within highly-exposed populations by several months to years.

The Walkerton Tragedy

To Fluoridate or Not
At the recommended concentration of 0.8-1.0 mg/L, fluoride reduces cavities by 18-40%, and there is little risk of fluorosis unless other exposures (e.g. toothpaste, rinses, mouthwash, etc.) are swallowed. Opposition raises concern that fluoride is not easily controlled and that children, and others may be more susceptible to health problems. However, public health experts strongly support fluoridation as an effective measure to prevent dental caries at the community level and reduce dental health inequities.
Soil

**Biological Hazards**
- biological contamination: tetanus, *Pseudomonas*

**Chemical Hazards**
- contamination sources: rupture of underground storage tanks, use of pesticides and herbicides, percolation of contaminated water runoffs, leaching of wastes from landfills, dust from smelting and coal burning power plants, residue of industrial waste/development (e.g. urban agriculture), lead deposition, leakage of transformers
- most common chemicals: petroleum hydrocarbons, solvents, lead, pesticides, motor oil, other industrial waste products
- infants and toddlers at highest risk of exposure due to hand-mouth behaviours
- dependent on contaminant: leukemia, kidney damage, liver toxicity, neuromuscular blockade, developmental damage to the brain and nervous system, skin rash, eye irritation, headache, nausea, fatigue

Food

Table 11. Comparison of Select Biological Contaminants of Food and Effects on Human Health

- other biological food contaminants include
  - viruses, mould toxins (e.g. aflatoxin has been associated with liver cancer), parasites (e.g. *Toxoplasmosis*, tapeworm), paralytic shellfish poisoning (rare), genetically modified organisms (controversial as to health risks/benefits)

**Chemical Hazards**
- many persistent organic pollutants are fat-soluble and undergo bioamplification
- drugs (antibiotics, hormones)
- inadequately prepared herbal medications
- food additives and preservatives
  - nitrates highest in cured meats; can be converted to carcinogenic nitrosamines
  - sulphites commonly used as preservatives; associated with sulphite allergy (hives, nausea, shock)
- pesticide residues
  - older pesticides (e.g. DDT) have considerable human health effects
  - polychlorinated biphenyls (PCBs)
  - effects (severe acne, numbness, muscle spasm, bronchitis) much more likely to be seen in occupationally exposed individuals than in the general population
- dioxins and furans
  - levels highest in fish and marine mammals, also present in breast milk can cause immunosuppression, liver disease, respiratory disease

---

Honey and Botulism
Although exceedingly rare, infant botulism has been documented as a form of food poisoning from *C. botulinum* found in honey. When an infant swallows spores of this bacterium, they grow and produce a toxin in the baby’s intestine. By the time an infant is 1, its gut has a healthy colony of “good” bacteria that prevents this from occurring.

Organic Foods
- Foods designated as “organic” in Canada must conform to the Organic Products Regulations enforced by the Canadian Food Inspection Agency
- Organic foods are not free of synthetic pesticide residues but typically contain smaller amounts compared to conventionally grown foods
- Currently, there has not been strong evidence to suggest that eating organic foods is safer or more nutritious compared to eating conventionally grown food

Organic foods and children, 2009
**Occupational Health**

- a field involved in the prevention of illness or injury and the promotion of health in the work environment
- services encompass “health promotion and protection (primary prevention), disease prevention (secondary prevention), and treatment and rehabilitation (tertiary prevention)” (Shah)
- occupational disease may be more difficult to recognize than occupational injury

**Taking an Occupational Health History**

- current and previous duties at place of employment
- exposures
  - identification: screen for chemical, metal, dust, biological, and physical hazards as well as psychological stressors; review relevant workplace MSDS
  - assessment: duration, concentration, route, exposure controls (e.g. ventilation, personal protective equipment)
  - temporal relationship: changes in symptoms in relationship to work environment
  - presence of similar symptoms in co-workers
  - non-work exposures: home, neighbourhood, hobbies

**Workplace Legislation**

- universal across Canada for corporate responsibility in the workplace: due diligence, application of Workplace Hazardous Materials Information System (WHMIS), existence of joint health and safety committees in the workplace with representatives from workers and management
- jurisdiction in Canada is provincial (90% of Canadian workers), except for 16 federally regulated industries (e.g. airports, banks, highway transport) under the Canada Labour Code
- Ontario’s Occupational Health and Safety Act
  - sets out rights of workers and duties of employers, procedures for workplace hazards, and law enforcement
  - workers have the right to:
    - participate (e.g. have representatives on joint health and safety committees)
    - know (e.g. be rained and have information about workplace hazards)
    - refuse work (e.g. workers can decline tasks they feel are overly dangerous)
      - note: For some occupations, this right is restricted if, for example, danger/risk is normal part of work or refusal would endanger others (e.g. police, firefighters, some health care workers)
    - stop work (e.g. ‘certified’ workers can halt work they feel is dangerous to other workers)
employers must take precautions to protect the health and safety of employees and investigate
concerns
enforced by Ministry of Labour via inspectors
Health Protection and Promotion Act (HPPA) (Ontario)
Medical Officer of Health has right to investigate and manage health hazards where workplace
exposures may impact non-workers (e.g. community members living close to the work site)

Workplace Health Promotion and Protection

pro-active preventative health measures can reduce workplace illness or injury
identifying workplace hazards (e.g. through material safety data sheets [MSDS])
assessing risk
reducing exposure: changes to work environment including elimination, substitution, and
isolation of hazard (e.g. engineering controls) more effective than changes to how people work (e.g.
administrative controls) and personal protective equipment

Workplace Disease Prevention and Identification

avoid the development of disease with pro-active worker health surveillance
periodic examinations to facilitate diagnosis before symptoms develop:
PFT for asthma (e.g. occupational dust exposure)
audiograms for hearing loss (e.g. occupational noise exposure)
substance misuse screening useful if concern surrounds decreased employee functioning

Workplace Treatment and Rehabilitation

treatment of the disease or injury to facilitate safe and timely return to the workforce
may require rehabilitation: retraining, change in job duties, and/or workers’ compensation (WSIB)
advice relevant authorities if necessary (e.g. report notifiable diseases to public health, conditions
impeding driving to Ministry of Transportation, see Other Reportable Conditions, PH25)

Appendix – Mandatory Reporting

Reportable Diseases

As an essential part of the health system, physicians in Canada are required by law to report certain
diseases to public health for the following reasons:
1. to control the outbreak
   if the disease presents an outbreak threat (e.g. measles, Salmonella, respiratory diseases in
   institutions)
2. to prevent spread
   if the disease presents a significant threat to individuals or a subset of the population (e.g. Lassa
   Fever)
3. for surveillance
   if the disease is preventable with immunization (e.g. polio, diphtheria, congenital rubella)
4. if infected individuals require education, treatment and/or partner notification (e.g. gonorrhea, TB)
5. reporting details (website, office etc.)
   some are more urgent than others (must contact MOH)
   physicians should also report unlisted diseases that appear in clusters
The following list is based on the reportable diseases in Ontario for 2015. Each province will have a similar legislation.

Note: Diseases marked * (and Influenza in institutions) should be reported immediately to the Medical Officer of Health by either telephone (24 hours a day, 7 days a week) or fax (Mon Fri, 8:30 am – 4:30 pm only). Other diseases can be reported the next working day by fax, phone or mail.

Source: Health Protection and Promotion Act, O. Reg. 559/91, amended to O. Reg 49/07 (update)

**Other Reportable Conditions**

- in addition to reporting diseases, physicians have a legal responsibility to report certain conditions.
- The list below highlights some reportable conditions for Ontario, but is not exhaustive. See your jurisdiction’s regulatory body for the full list.

**Child Abuse – to local Children’s Aid Society (CAS)**
- all child abuse and neglect where reasonable grounds to suspect exist (including physical harm, emotional harm, sexual harm, and neglect)
- duty to report is ongoing: if additional reasonable grounds are suspect, a further report to CAS is necessary

**Unfit to Drive – to provincial Ministry of Transportation**
- all patients with a medical condition (e.g. dementia, untreated epilepsy) that may impede their driving ability
- if a physician does not report and the driver gets into an accident, the physician may be held liable

**Unfit to Fly – to federal Ministry of Transportation**
- all patients believed to be flight crew members or air traffic controller with a medical or optometric condition that is likely to constitute a hazard to aviation safety

**Gunshots Wounds – to local police service**
- all patients with a gunshot or stab wounds
- self-inflicted knife wounds are not reportable

Psychiatric Assessment

History

Identifying Data
- necessary: name, age, sex/gender, marital status, occupation/source of financial support, place/type of residency
- adjunct: makeup of household, education, ethnicity, nationality, immigration history (if applicable), religion, referral source, known or unknown to treatment team

Reliability of Patient as a Historian
- indicate if, and for what content; utilize collateral source (e.g. parent, teacher) if patient unable/unwilling to be interviewed

Chief Complaint
- in patient's own words, duration

History of Present Illness
- reason for seeking help (that day), current symptoms (onset, duration and course), stressors, supports, functional status, relevant associated symptoms (pertinent positives and negatives)
- current medication use, doses, and adherence
- safety screen: endangering self or others, dependents at home (e.g. children, pets), ability to drive safely, ability to care for self (e.g. eating, hygiene, taking medications)

Psychiatric Functional Inquiry
- mood: depression, mania
- anxiety: worries, panic attacks, phobias, history of trauma
- obsessive-compulsive: obsessions, compulsions
- psychosis: hallucinations, delusions
- risk assessment: suicidal ideation, plan, intent, history of attempts (see Suicide PS4)
- organic: EtoH/drug use or withdrawal, illness, dementia

Past Psychiatric History
- all previous psychiatric diagnoses, psychiatric contacts, treatments (pharmacological and non-pharmacological), and hospitalizations
- include past suicide attempts, substance use/abuse, and problems/encounters with the legal system

Past Medical/Surgical History
- all medical, surgical, neurological (e.g. head trauma, seizures), and psychosomatic illnesses
- current medications, allergies

Family Psychiatric/Medical History
- family members: ages, occupations, personalities, medical or genetic illnesses and treatments, relationships with parents/siblings
- family psychiatric history: any past or current psychiatric illnesses and hospitalizations, suicide, substance abuse

Past Personal/Developmental History (as relevant)
- prenatal and perinatal history (desired vs. unwanted pregnancy, maternal and fetal health, domestic violence, maternal substance use and exposures, complications of pregnancy/delivery)
- early childhood to age three (developmental milestones, activity/attention level, family stability, attachment figures)
- middle childhood to age 11 (school performance, peer relationships, fire-setting, stealing, incontinence)
- late childhood to adolescence (drugs/alcohol, legal problems, peer and family relationships)
- history of physical or sexual abuse
- adulthood (education, occupations, relationships)
- personality before current illness, recent changes in personality
- psychosexual history (puberty, first sexual encounter, romantic relationships, gender roles, sexual dysfunction)

Screening Questions for Major Psychiatric Disorders
- Have you ever been feeling down, depressed or hopeless?
- Do you feel anxious or worry about things?
- Have there been a time in your life where you have felt euphoric, extremely talkative, had a lot of energy, and a decreased need for sleep?
- Have you ever thought of harming yourself or committing suicide?

Psychiatric Functional Inquiry

MOAPS
Mood
Organic (e.g. substances and organic disease)
Anxiety
Psychosis
Safety

Always Remember to Ask About Abuse
See Family Medic ne, FM26
Mental Status Exam

General Appearance
- posture, gait, grooming, hygiene, manner of dress, body habitus, facial expression, chronological vs. apparent age, relaxed or in distress

Behaviour
- psychomotor activity (agitation, retardation), abnormal movements or lack thereof (tremors, akathisia, tardive dyskinesia, paralysis), attention level and eye contact, attitude toward examiner (ability to interact, level of cooperation)

Speech
- rate (e.g. pressured, slowed), rhythm/fluency, volume, tone, articulation, quantity, spontaneity

Mood and Affect
- mood: subjective emotional state (in patient's own words)
- affect: objective emotional state inferred from emotional responses to stimuli; described in terms of
  - quality ( euthymic, depressed, elevated, anxious, irritable)
  - range (full, restricted, flat, blunted)
  - stability (fixed, labile)
  - mood congruence (inferred by comparing the patient's subjective mood with their affect)
- appropriateness to thought content
- some clinicians use 0-10 scales when rating mood to help get a subjective norm for each patient that can help establish changes over time and with treatment

Thought Process/Form
- coherence (coherent, incoherent)
- logic (logical, illogical)
- stream
  - goal-directed: clearly answers questions in a linear, organized, logical fashion
  - circumstantial: speech is indirect and delayed in reaching its goal; eventually comes back to the point
  - tangential: speech is oblique or irrelevant; does not come back to the original point
  - loosening of associations/derailment: illogical shifting between topics
  - flight of ideas: quickly skipping from one idea to another where the ideas are marginally connected, usually associated with mania
  - word salad: jumble of words lacking meaning or logical coherence
- perseveration: repetition of the same verbal or motor response to stimuli
- echolalia: repetition of phrases or words spoken by someone else
- thought blocking: sudden cessation of flow of thought and speech
- clang associations: speech based on sound such as rhyming or punning
- neologism: use of novel words or of existing words in a novel fashion

Thought Content
- suicidal ideation/ homicidal ideation
- frequency and pervasiveness of thoughts, formulation of plan, means to plan, intent, active vs. passive, protective factors
- preoccupations, ruminations: reflections/thoughts at length, not fixed or false
- obsession: recurrent and persistent thought, impulse, or image which is intrusive or inappropriate and unwanted
  - cannot be stopped by logic or reason
  - causes marked anxiety and distress
  - common themes: contamination, orderliness, sexual, pathological doubt/worry/guilt
  - magical thinking: belief that thinking something will make it happen, normal in children and certain cultures
  - ideas of reference: similar to delusion of reference, but less fixed (the reality of the belief is questioned)
  - overvalued ideas: unusual/odd beliefs that are not of delusional proportions
  - first rank symptoms of schizophrenia: thought insertion/withdrawal/broadcasting
  - delusion: a fixed false belief that is out of keeping with a person's cultural or religious background and is firmly held despite incontrovertible proof to the contrary

Perception
- hallucination: sensory perception in the absence of external stimuli that is similar in quality to a true perception
  - auditory (most common), visual, gustatory, olfactory, tactile
- illusion: misperception of a real external stimulus (such as mistaking a coat on a rack as a person late at night)
- depersonalization: change in self-awareness such that the person feels unreal, distant, or detached from his or her body, and/or unable to feel emotion
- derealization: feeling that the world/outer environment is unreal
Cognition
- level of consciousness (alert, reduced, obtunded)
- orientation: time, place, person
- memory: immediate, recent, remote
- global evaluation of intellect (below average, average, above average, in keeping with person's education)
- intellectual functions: attention, concentration, calculation, abstraction (proverb interpretation, similarities test), language, communication
- MMSE/MOCA useful as standard screening assessments of cognition

Insight
- patient's ability to realize that he or she has a physical or mental illness and to understand its implications (none, limited, partial, full)

Judgment
- patient's ability to understand relationships between facts and draw conclusions that determine one's actions

Assessment and Plan

Historical Multiaxial Model
- since DSM-5, this model is no longer used for psychiatric diagnosis. Instead, relevant psychiatric and medical diagnoses are simply listed. Nevertheless, we offer it here as a possible framework for psychiatric patient assessment, as many physicians still employ it.

Multiaxial Assessment
- Axis I: differential diagnosis of DSM-5 clinical disorders
- Axis II: personality disorders, developmental disability
- Axis III: general medical conditions potentially relevant to understanding/management of the mental disorder
- Axis IV: psychosocial and environmental issues
- Axis V: Global Assessment of Functioning (GAF, 0 to 100) incorporating effects of axes I to IV

After History and MSE, the assessment and plan is recorded

Assessment/Problem Formulation
- identify predominant symptom cluster (mood, anxiety, psychosis organic) causing the most distress/interference, persist when other symptom categories not present (e.g. psychosis in the absence of mood symptoms)
- dominating symptoms will direct differential
- consider current issues as they relate to an individual's factors in three domains: biological, psychological, and social
- for each category: predisposing, precipitating, perpetuating, and protecting factors are considered

Approach to Management
- consider short-term and long-term, and three types: biological (e.g. pharmacotherapy), psychological (e.g. CBT), and social (e.g. support group)

Suicide

Importance
- must be screened for in every encounter; part of risk assessment along with violent/homicidal ideation

Approach
- ask every patient – e.g. "Have you had any thoughts of wanting to harm or kill yourself?"
- classify ideation
  - passive ideation: would rather not be alive but has no active plan for suicide
    - e.g. "I'd rather not wake up" or "I would not mind if a car hit me"
  - active ideation
    - e.g. "I think about killing myself"
- assess risk
  - plan: "Do you have a plan as to how you would end your life?"
  - intent: "Do you think you would actually carry out this plan?" "If not, why not?"
  - past attempts: highest risk if previous attempt in past year
    - ask about lethality, outcome, medical intervention
- assess suicidal ideation
  - onset and frequency of thoughts: "When did this start?" or "How often do you have these thoughts?"
  - control over suicidal ideation: "How do you cope when you have these thoughts?" "Could you call someone for help?"
  - intention: "Do you really want to end your life?" or "Do you wish to kill yourself?"
  - intended lethality: "What do you think would happen if you actually took those pills?"
  - access to means: "How will you get a gun?" or "Which bridge do you think you would go to?"
  - time and place: "Have you picked a date and place? Is it in an isolated location?"
  - provocative factors: "What makes you feel worse (e.g. being alone?)"
• protective factors: “What keeps you alive (e.g. friends, family, pets, faith, therapist)?”
• final arrangements: “Have you written a suicide note? Made a will? Given away your belongings?”
• practiced suicide or aborted attempts: “Have you ever put the gun to your head? Held the mediations in your hand? Stood at the bridge?”
• ambivalence: “I wonder if there is a part of you that wants to live, given that you came here for help?”

Assessment of Suicide Attempt
• setting (isolated vs. others present/chance of discovery)
• planned vs. impulsive attempt, triggers/stressors
• substance use/intoxication
• medical attention (brought in by another person vs. brought in by self to ED)
• time lag from suicide attempt to ED arrival
• expectation of lethality, dying
• reaction to survival (guilt/remorse vs. disappointment/self-blame)

Epidemiology
• attempted/completed = 20:1
• M:F = 1:4 for attempts, 3:1 for completed

Risk Factors
• epidemiologic factors
  • age: increases after age 14, second most common cause of death for ages 15-24, highest rates of completion in persons >65 yr
  • sex: male
  • race/ethnic background: white or Native Canadians
  • marital status: widowed/divorced
  • living situation: alone; no children <18 yr old in the household
  • other: stressful life events, access to firearms
• psychiatric disorders
  • mood disorders (15% lifetime risk in depression; higher in bipolar)
  • anxiety disorders (especially panic disorder)
  • schizophrenia (10-15% risk)
  • substance abuse (especially alcohol – 15% lifetime risk)
  • eating disorders (5% lifetime risk)
  • conduct disorder
  • personality disorders (borderline, antisocial)
• past history
  • prior suicide attempt
  • family history of suicide attempt/completion

Clinical Presentation
  symptoms associated with suicide
  • hopelessness
  • anhedonia
  • insomnia
  • severe anxiety
  • impaired concentration
  • psychomotor agitation
  • panic attacks

Management
• proper documentation of the clinical encounter and rationale for management is essential
• higher risk (hospitalization needs to be strongly considered)
  • patients with a plan and intention to act on the plan, access to lethal means, recent social stressors, and symptoms suggestive of a psychiatric disorder
  • do not leave patient alone; remove potentially dangerous objects from room
  • if patient refuses to be hospitalized, complete form for involuntary admission (Form 1)
• lower risk
  • patients who are not actively suicidal, with no plan or access to lethal means
  • discuss protective factors and supports in their life, remind them of what they live for; promote survival skills that helped them through previous suicide attempts
  • make a safety plan that could include an agreement that they will:
    • not harm themselves
    • avoid alcohol, drugs, and situations that may trigger suicidal thoughts
    • follow-up with you at a designated time
    • contact a health care worker, call a crisis line, or go to an emergency department if they feel unsafe or if their suicidal feelings return or intensify
• depression: consider hospitalization if symptoms severe or if psychotic features are present; otherwise outpatient treatment with good supports and SSRIs/SNRIs
• alcohol-related: usually resolves with abstinence for a few days; if not, suspect depression
• personality disorders: crisis intervention, may or may not hospitalize
• schizophrenia/psychosis: hospitalization might be necessary
• parasuicide/self-mutilation: long-term psychotherapy with brief crisis intervention when necessary
Psychotic Disorders

Definition
- characterized by a significant impairment in reality testing
- delusions or hallucinations (with/without insight into their pathological nature)
- behaving in a disorganized way so that it is reasonable to infer that reality testing is disturbed

Differential Diagnosis of Psychosis

Approach
- differentiate among psychotic disorders and distinguish them from other primary diagnoses with psychotic features
- consider symptoms, persistence, and time
- symptoms: what symptoms exist? The primary diagnosis needs full criteria to be met
  - mood: depressive episodes with psychotic features, manic episodes with psychotic features
  - psychotic: consider symptoms in Criterion A of schizophrenia, such as delusions, hallucinations, disorganized speech, grossly disorganized/catatonic behaviour, negative symptoms (i.e. diminished emotional expression or avolition)
- persistence: is there a time when certain symptom clusters are present without other clusters?
  - e.g. if there is a period of time with mood symptoms but not psychotic symptoms, consider mood disorder
  - e.g. if two weeks where psychotic symptoms persist in the absence of mood symptoms, consider schizoaffective disorder
- time: how long have the symptoms been present?

Table 1. Differentiating Psychotic Disorders

<table>
<thead>
<tr>
<th>Disorder</th>
<th>Psychotic Symptoms</th>

</tr>
<tr>
<td>2º to Mood Disorder</td>
<td>Mood symptoms dominant + delusions/ hallucinations (mood congruent)</td>
<td>Psychosis may be present for the duration of the mood episode</td>
</tr>
</tbody>
</table>

Schizophrenia

DSM-5 Diagnostic Criteria for Schizophrenia

A. two (or more) of the following, each present for a significant portion of time during a 1 mo period (or less if successfully treated). At least one of these must be (1), (2), or (3)
1. delusions
2. hallucinations
3. disorganized speech (e.g. frequent derailment or incoherence)
4. grossly disorganized or catatonic behaviour
5. negative symptoms (i.e. diminished emotional expression or avolition)

B. decreased level of function: for a significant portion of time since onset, one or more major areas affected (e.g. work, interpersonal relations, self-care) is markedly decreased (or if childhood/adolescent onset, failure to achieve expected level)

C. at least 6 mo of continuous signs of the disturbance. Must include at least 1 mo of symptoms (or less if successfully treated) that meet Criterion A (i.e. active-phase symptoms) and may include periods of prodromal or residual symptoms, during which, disturbance may manifest by only negative symptoms or by two or more Criterion A symptoms present in an attenuated form (e.g. odd beliefs, unusual perceptual experiences)

D. rule out schizoaffective disorder and depressive or bipolar disorder with psychotic features because either 1) no major depressive or manic episodes have occurred concurrently with the active-phase symptoms, or 2) if mood episodes have occurred during active-phase symptoms, they have been present for a minority of the total duration of the active and residual periods of the illness

E. rule out other causes: GMC, substances (e.g. drug of abuse, medication)

Disorganized Behaviours in Schizophrenia
- Catatonic stupor: fully conscious, but immobile, mute, and unresponsive
- Catatonic excitement: uncontrolled and aimless motor activity, maintaining bizarre positions for a long time
- Stereotypy: repeated but non-goal-directed movement (e.g. rocking)
- Mannerisms: goal-directed activities that are odd or out of context (e.g. grimacing)
- Echopraxia: imitates movements and gestures of others
- Automatic obedience: carries out simple commands in robot-like fashion
- Inappropriate affect, neglect of self-care, other odd behaviours (random shouting)
Epidemiology
- prevalence: 0.3-0.7%, M:F = 1:1
- mean age of onset: females late-20s; males early- to mid-20s
- suicide risk: 10% die by suicide, 30% attempt suicide

Etiology
- multifactorial: disorder is a result of interaction between both biological and environmental factors
  - genetic: 40% concordance in monozygotic (MZ) twins; 46% if both parents have schizophrenia; 10% of dizygotic (DZ) twins, siblings, children affected; vulnerable genes include Disrupted-in-Schizophrenia 1 (DISC1); neuregulin 1 (NRG 1); dystrobrevin binding protein (dysbindin (DTNBP1); catechol-O-methyltransferase (COMT); d-amino acid oxidase activator (DAOA); metabotropic glutamate receptor 3 (GRM3); and brain-derived neurotrophic factor (BDNF)
  - neurochemistry (’dopamine hypothesis’): excess activity in the mesolimbic dopamine pathway may mediate the positive symptoms of psychosis, while decreased dopamine in the prefrontal cortex may mediate negative and cognitive symptoms. GABA, glutamate, and ACh dysfunction are also thought to be involved
  - neuroanatomy: decreased frontal lobe function; asymmetric temporal/limbic function; decreased basal ganglia function; subtle changes in thalamus, cortex, corpus callosum, and ventricles; cytotoxicarchitectural abnormalities
  - neuroendocrinology: abnormal growth hormone, prolactin, cortisol, and ACTH
  - neuropsychology: global defects seen in attention, language, and memory suggest disrupted connectivity of neural networks
  - environmental: indirect evidence of cannabis use, geographical variance, winter season of birth obstetrical complications, and prenatal viral exposure

Pathophysiology
- neurodegenerative theory: natural history may be a rapid or gradual decline in function and ability to communicate
  - glutamate system may mediate progressive degeneration by excitotoxic mechanism which leads to production of free radicals
  - neurodevelopmental theory: abnormal development of the brain from prenatal life
    - neurons fail to migrate correctly, make inappropriate connections, and apoptosis in later life

Comorbidity
- substance-related disorders
- anxiety disorders
- reduced life expectancy secondary to medical comorbidities (e.g. obesity, diabetes, metabolic syndrome, CV/pulmonary disease)

Management of Schizophrenia
- biological / somatic
  - acute treatment and maintenance: antipsychotics (haloperidol, risperidone, olanzapine, paliperidone; clozapine if refractory); often regimens of IM q2-4 wk used in severe cases to ensure adherence
  - adjunctive: ± mood stabilizers (for aggression/impulsiveness - lithium, valproate, carbamazepine) ± anxiolytics ± ECT
  - treat for at least 1-2 years after the first episode, at least 5 years after multiple episodes (relapse causes severe deterioration)
- psychosocial
  - psychotherapy (individual, family, group), supportive, CBT (see Table 14, PS41)
  - ACT (Assertive Community Treatment): mobile mental health teams that provide individualized treatment in the community and help patients with medication adherence, basic living skills, social support, job placements, resources
  - social skills training, employment programs, disability benefits
  - housing (group home, boarding home, transitional home)

Course and Prognosis
- majority of individuals display some type of prodromal phase
  - course is variable: some individuals have exacerbations and remissions while others remain chronically ill; accurate prediction of the long-term outcome is not possible
  - negative symptoms may be prominent early in the illness and may become more prominent and more disabling later on; positive symptoms appear and typically diminish with treatment
  - over time: 1/3 improve, 1/3 remain the same, 1/3 worsen

Good Prognostic Factors
- Acute onset
- Shorter duration of prodrome
- Female gender
- Good cognitive functioning
- Good premorbid functioning
- No family history
- Presence of affective symptoms
- Absence of structural brain abnormalities
- Good response to drugs
- Good support system
Psychotic Disorders

Schizophreniform Disorder

Diagnosis
Adopted/summarized from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
• criteria A, D, and E of schizophrenia are met; an episode of the disorder lasts for at least 1 mo but less than 6 mo
• if the symptoms have extended past 6 mo the diagnosis becomes schizophrenia
• specifiers: with/without good prognostic features (e.g. acute onset, confusion, good premorbid functioning, absence of blunt/flat affect) with catatonia, current severity based on quantitative assessment of primary symptoms of psychosis

Treatment
• similar to acute schizophrenia

Prognosis
• better than schizophrenia; begins and ends more abruptly; good pre and post-morbid function

Brief Psychotic Disorder

Diagnosis
Adopted/summarized from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
• criteria A1-A4, D, and E of schizophrenia are met; an episode of the disorder lasts for at least 1 d but less than 1 mo with eventual full return to premorbid level of functioning
• specifiers: with/without marked stressors, with postpartum onset, with catatonia, current severity
• can occur after a stressful event or postpartum (see Postpartum Mood Disorders, PS12)

Treatment
• secure environment, antipsychotics, anxiolytics

Prognosis
• good, self-limiting, should return to pre-morbid function within 1 mo

Schizoaffective Disorder

DSM-5 Diagnostic Criteria for Schizoaffective Disorder
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
A. concurrent psychosis (criterion A of schizophrenia) and major mood episode - uninterrupted period of illness
B. delusions or hallucinations for 2 or more wk in the absence of a major mood episode during the lifetime duration of the illness
C. major mood episode symptoms are present for the majority of the total duration of the active and residual periods of the illness
D. the disturbance is not attributable to the effects of a substance or another medical condition
• specifiers: bipolar type, depressive type, with catatonia, type of episode, severity

Epidemiology
• one-third as prevalent as schizophrenia; schizoaffective disorder bipolar type more common in young adults, schizoaffective disorder depressive type more common in older adults
• depressive symptoms correlated with higher suicide risk

Treatment
• antipsychotics, mood stabilizers, antidepressants

Prognosis
• between that of schizophrenia and of mood disorder

Delusional Disorder

DSM-5 Diagnostic Criteria for Delusional Disorder
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
A. the presence of one (or more) delusions with a duration of 1 mo or longer
B. criterion A for schizophrenia has never been met
• Note: hallucinations, if present, are not prominent and are related to the delusional theme
C. apart from the impact of the delusion(s) or its ramifications, functioning is not markedly impaired, and behaviour is not obviously bizarre or odd
D. if manic or major depressive episodes have occurred, these have been brief relative to the duration of the delusional periods
E. the disturbance is not attributable to the physiological effects of a substance or another medical condition and is not better explained by another mental disorder
• subtypes: erotomaniac, grandiose, jealous, persecutory, somatic, mixed, unspecified
• further specify: bizarre content, type of episode (e.g. first episode, multiple episode), severity
Treatment
• psychotherapy, antipsychotics, antidepressants

Prognosis
• chronic, unremitting course but high level of functioning; a portion will progress to schizophrenia

Mood Disorders

Definitions
• accurate diagnosis of a mood disorder requires a careful past medical and psychiatric history to detect past mood episodes and to rule out whether these episodes were secondary to substance use, a medical condition, a loss, etc
• mood episodes represent a combination of symptoms comprising a predominant mood state that is abnormal in quality or duration (e.g. major depressive, manic, mixed, hypomanic). DSM-5 Criteria for mood episodes are listed below
• types of mood disorders include
  - depressive (major depressive disorder, persistent depressive disorder)
  - bipolar (bipolar I/II disorder, cyclothymia)
  - secondary to general medical condition, substances, medications, other psychiatric issue

Medical Workup of Mood Disorder
• routine screening: physical exam, CBC, thyroid function test, extended electrolytes, urinalysis, drug screen, medications list
• additional screening: neurological consultation, chest X-ray, ECG, CT head

Mood Episodes

DSM-5 Diagnostic Criteria for Major Depressive Episode
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
A. ≥5 of the following symptoms have been present during the same 2 wk period and represent a change from previous functioning; at least one of the symptoms is either 1) depressed mood or 2) loss of interest or pleasure (anhedonia)

Note: do not include symptoms that are clearly attributable to another medical condition
• depressed mood most of the day, nearly every day, as indicated by either subjective report or observation made by others
• markedly diminished interest or pleasure in all, or almost all, activities most of the day, nearly every day
• significant and unintentional weight loss/weight gain, or decrease/increase in appetite nearly every day
• insomnia or hypersomnia nearly every day
• psychomotor agitation or retardation nearly every day
• fatigue or loss of energy nearly every day
• feelings of worthlessness or excessive or inappropriate guilt (which may be delusional) nearly every day (not merely self-reproach or guilt about being sick)
• diminished ability to think or concentrate, or indecisiveness, nearly every day
• recurrent thoughts of death (not just fear of dying), recurrent suicidal ideation without a specific plan, or a suicide attempt or a specific plan for committing suicide

B. the symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning

C. the episode is not attributable to the direct physiological effects of a substance or a GMC

DSM-5 Criteria for Manic Episode
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. a distinct period of abnormally and persistently elevated, expansive, or irritable mood, and abnormally and persistently increased goal-directed activity or energy, lasting ≥1 wk and present most of the day, nearly every day (or any duration if hospitalization is necessary)

B. during the period of mood disturbance and increased energy or activity, ≥3 of the following symptoms have persisted (4 if the mood is only irritable) have been present to a significant degree and represent a noticeable change from usual behaviour
• inflated self-esteem or grandiosity
• decreased need for sleep (e.g. feels rested after only 3 h of sleep)
• more talkative than usual or pressure to keep talking
• flight of ideas or subjective experience that thoughts are racing
• distractibility (i.e. attention too easily drawn to unimportant or irrelevant external stimuli)
• increase in goal-directed activity (either socially, at work or school, or sexually) or psychomotor agitation
• excessive involvement in pleasurable activities that have a high potential for painful consequences (e.g. engaging in unrestrained spending sprees, sexual indiscretions, or foolish business investments)

C. the mood disturbance is sufficiently severe to cause marked impairment in social/occupational functioning or to necessitate hospitalization to prevent harm to self or others, or there are psychotic features

D. the episode is not attributable to the physiological effects of a substance or another medical condition
Note: A full manic episode that emerges during antidepressant treatment but persists at a fully syndromal level beyond the physiological effect of that treatment is sufficient evidence for a manic episode, and therefore, a bipolar I diagnosis. Note: Criteria A-D constitute a manic episode. At least one lifetime manic episode is required for the diagnosis of bipolar I disorder.

Hypomanic Episode
- criterion A and B of a manic episode is met, but duration is ≥4 days
- episode associated with an uncharacteristic change in functioning that is observable by others but not severe enough to cause marked impairment in social or occupational functioning or to necessitate hospitalization
- absence of psychotic features (if these are present the episode is, by definition, manic)

Mixed Features
- an episode specifier in bipolar or depression that indicates the presence of both depressive and manic symptoms concurrently, classified by the disorder and primary mood episode component (e.g. bipolar disorder, current episode manic, with mixed features)
- clinical importance due to increased suicide risk
- if found in patient diagnosed with major depression, high index of suspicion for bipolar disorder
- while meeting the full criteria for a major depressive episode, the patient has on most days ≥3 of criteria B for a manic episode
- while meeting the full criteria for a manic/hypomanic episode, the patient has on most days ≥3 of criteria A for a depressive episode (the following criterion A cannot count: psychomotor agitation, insomnia, difficulties concentrating, weight changes)

Depressive Disorders

MAJOR DEPRESSIVE DISORDER

DSM-5 Diagnostic Criteria for Major Depressive Disorder (MDD)
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. presence of a MDE
B. the MDE is not better accounted for by schizoaffective disorder and is not superimposed on schizophrenia, schizoaffective disorder, delusional disorder, or psychotic disorder NOS
C. there has never been a manic episode or a hypomanic episode

Note: This exclusion does not apply if all of the manic-like, or hypomanic-like episodes are substance or treatment-induced or are due to the direct physiological effects of another medical condition

- specifiers: with anxious distress, mixed features, melancholic features, atypical features, mood-congruent psychotic features, mood-incongruent psychotic features, catatonia, peripartum onset, seasonal pattern
- single vs. recurrent is an episode descriptor that carries prognostic significance. Recurrent is classified as the patient having two or more distinct MDE episodes; to be considered separate the patient must have gone 2 consecutive months without meeting criteria

Epidemiology
- lifetime prevalence: 12%
- peak prevalence age 15-25 yr (M:F = 1:2)

Etiology
- biological
  - genetic: 65-75% MZ twins; 14-19% DZ twins, 2-4 fold increased risk in first-degree relatives
  - neurotransmitter dysfunction: decreased activity of 5-HT, NE, and DA at neuronal synapse; changes in GABA and glutamate; various changes detectable by fMRI
  - neuroendocrine dysfunction: abnormal HPA axis activity
  - neuroanatomy and neurophysiology: decreased hippocampal volume, increased size of ventricles; decreased REM latency and slow-wave sleep; increased REM length
  - immunologic: increased pro-inflammatory cytokines IL-6 and TNF
  - secondary to medical condition, medication, substance use disorder
- psychosocial
  - psychodynamic (e.g. low self-esteem, unconscious aggression towards self or loved ones, disordered attachment)
  - cognitive (e.g. distorted schemata, Beck's cognitive triad: negative views of the self, the world, and the future)
  - environmental factors (e.g. job loss, bereavement, history of abuse or neglect, early life adversity)
  - comorbid psychiatric diagnoses (e.g. anxiety, substance abuse, developmental disability, dementia, eating disorder)

Risk Factors
- sex: F>M, 2:1
- family history: depression, alcohol abuse, suicide attempt or completion
- childhood experiences: loss of parent before age 11, negative home environment (abuse, neglect)
- personality: neuroticism, insecure, dependent, obsessive
- recent stressors: illness, financial, legal, relational, academic
- lack of intimate, confiding relationships or social isolation
- low socioeconomic status

Antidepressants for Depression in Physical Medical Illness
Purpose: To evaluate whether antidepressants are clinically effective and acceptable for treatment of depression in patients who also have a physical illness.
Methods: Systematic review of RCTs comparing any antidepressant drug as defined by the British National Formulary with placebo or no treatment, in patients aged 16 years and over who have been formally diagnosed with depression by any criterion, and have a specified physical disorder. Main outcome measures were number of individuals demonstrating improvement or recovery by the end of the trial, and number completing treatment (as a proxy for treatment acceptability).
Results: Eighteen studies with 838 patients having varied physical illnesses were included. Patients treated with antidepressants were significantly more likely to improve than those given placebo (13 studies, OR 0.37, 95% CI 0.27-0.51) or no treatment (1 study, OR 3.45, 95% CI 1.33-9.30) (number needed to treat relative to placebo = 4.2, 3.2-6.4).
Most antidepressants were associated with a small but significant increase in dropouts (OR 1.36, 1.14-2.40; NNH 9.8, 5.4-42.9). Among two studies evaluating impact on function and quality of life, drug was found to be better than no treatment for HIV patients, and drug was not significantly different than placebo in lung disease patients. Tetracyclines appeared to be more effective than SSRI but also more likely to produce dropouts, based on non-randomized comparisons between trials.
Conclusion: Antidepressants cause improvements in depression in patients with various physical illnesses significantly more frequently than placebo or no treatment. Antidepressants were reasonably acceptable to patients. Tetracyclines may be more effective than SSRI but may also produce more dropouts. As such, antidepressants should at least be considered in those with comorbid physical illness and depression.
Depression in the Elderly

- affects about 15% of community residents >65 yr old; up to 50% in nursing homes
- high suicide risk due to social isolation, chronic medical illness, decreased independence
- suicide peak: males aged 80-90; females aged 50-65
- dysphoria may not be a reliable indicator of depression in those >85 yr
- often present with somatic complaints (e.g. changes in weight, sleep, energy) or anxiety symptoms
- may have prominent cognitive changes after onset of mood symptoms (dementia syndrome of depression)
- see Table 3, PS21, for a comparison of delirium and dementia

Treatment

- lifestyle: increased aerobic exercise, mindfulness-based stress reduction, zinc supplementation
- biological: SSRIs, SNRIs, other antidepressants, somatic therapies (see Pharmacotherapy, PS42, and Somatic Therapies, PS49)
  - 1st line pharmacotherapy: sertraline, escitalopram, venlafaxine, mirtazapine
  - for partial or non-response, can change class or add augmenting agent (bupropion, quetiapine-XR, aripiprazole, lithium)
  - typical response to antidepressant treatment: physical symptoms improve at 2 wk, mood/cognition by 4 wk; if no improvement after 4 wk at a therapeutic dosage, alter regimen
  - ECT: currently fastest and most effective treatment for MDD. Consider in severe, psychotic or treatment resistant cases
  - rTMS: early data support efficacy equivalent to ECT with good safety and tolerability
  - phototherapy: especially if seasonal component, shift work, sleep dysregulation
  - psychological
    - individual therapy (interpersonal, CBT), family therapy, group therapy
    - social: vocational rehabilitation, social skills training
    - experimental: magnetic seizure therapy, deep brain stimulation, vagal nerve stimulation, ketamine

Prognosis

- one year after diagnosis of MDD without treatment: 40% of individuals still have symptoms that are sufficiently severe to meet criteria for MDD, 20% continue to have some symptoms that no longer meet criteria for MDD, 40% have no mood disorder

PERSISTENT DEPRESSIVE DISORDER

DSM-5 Diagnostic Criteria for Persistent Depressive Disorder

Note: in DSM-IV-TR this was referred to as Dysthymia

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. depressed mood for most of the day, for more days than not, as indicated either by subjective account or observation by others, for ≥2 yr

B. presence, while depressed, of ≥2 of the following:
  - poor appetite or overeating
  - insomnia or hypersomnia
  - low energy or fatigue
  - low self-esteem
  - poor concentration or difficulty making decisions
  - feelings of hopelessness

C. during the 2 yr period (1 yr for children or adolescents) of the disturbance, the person has never been without the symptoms in criteria A and B for more than 2 mo at a time

D. criteria for a major depressive disorder may be continuously present for 2 yr

E. there has never been a manic episode or a hypomanic episode, and criteria have never been met for cyclothymic disorder

F. the disturbance is not better explained by a persistent schizoaffective disorder, schizophrenia, delusional disorder, or other specified or unspecified schizophrrenia spectrum and other psychotic disorder

G. the symptoms are not due to the direct physiological effects of a substance or another medical condition

H. the symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning

Epidemiology

- lifetime prevalence: 2.3%; M=F

Treatment

- psychological
  - traditionally, psychotherapy was the principal treatment for persistent depressive disorder; recent evidence suggests some benefit, but generally inferior to pharmacological treatment. Combinations of the two may be most efficacious
  - biological
    - antidepressant therapy: SSRIs (e.g. sertraline, paroxetine), TCAs (e.g. imipramine) as an outpatient
Postpartum Mood Disorders

Postpartum “Blues”
- transient period of mild depression, mood instability, anxiety, decreased concentration; considered to be normal changes in response to fluctuating hormonal levels, the stress of childbirth, and the increased responsibilities of motherhood
- occurs in 50-80% of mothers; begins 2-4 d postpartum, usually lasts 48 h, can last up to 10 d
- does not require psychotropic medication
- usually mild or absent; feelings of inadequacy, anhedonia, thoughts of harming baby, suicidal thoughts

MAJOR DEPRESSIVE DISORDER WITH PERIPARTUM ONSET (POSTPARTUM DEPRESSION)

Clinical Presentation
- MDD with onset during pregnancy or within 4 wk following delivery
- typically lasts 2-6 mo; residual symptoms can last up to 1 yr
- may present with psychosis (rare, 0.2%), usually associated with mania, but also with MDE
- severe symptoms include extreme disinterest in baby, suicidal and infanticidal ideation

Epidemiology
- occurs in 10% of mothers, risk of recurrence 50%

Risk Factors
- previous history of a mood disorder (postpartum or otherwise), family history of mood disorder
- psychosocial factors: stressful life events, unemployment, marital conflict, lack of social support, unwanted pregnancy, colicky or sick infant

Treatment
- psychotherapy (CBT or IPT)
- short-term safety of maternal SSRIs for breastfeeding infants established; long-term effects unknown
- if depression severe or psychotic symptoms present, consider ECT

Prognosis
- impact on child development: increased risk of cognitive delay, insecure attachment, behavioural disorders
- treatment of mother improves outcome for child at 8 mo through increased mother-child interaction

Bipolar Disorders

BIPOLAR I / BIPOLAR II DISORDER

Definition
- Bipolar I Disorder
  - disorder in which at least one manic episode has occurred
  - if manic symptoms lead to hospitalization, or if there are psychotic symptoms, the diagnosis is BP I
  - commonly accompanied by at least 1 MDE but not required for diagnosis
  - time spent in mood episodes: 53% asymptomatic, 32% depressed, 9% cycling/mixed, 6% hypo/manic
- Bipolar II Disorder
  - disorder in which there is at least 1 MDE, 1 hypomanic and no manic episodes
  - while hypomania is less severe than mania, Bipolar II is not a “milder” form of Bipolar I
  - time spent in mood episodes: 46% asymptomatic, 50% depressed, 1% cycling/mixed, 2% hypo/manic
- Bipolar II is often missed due to the severity and chronicity of depressive episodes and low rates of spontaneous reporting and recognition of hypomanic episodes

Classification
- classification of bipolar disorder involves describing the disorder (I or II) and the current or most recent mood episode as either manic, hypomanic, or depressed
- specifiers: with anxious distress, depressed with mixed features, hypo/manic with mixed features, melancholic features, atypical features, mood-congruent or -incongruent psychotic features, catatonia, peripartum onset, seasonal pattern, rapid cycling (4+ mood episodes in 1 yr)

Epidemiology
- lifetime prevalence: 1% BPI, 1.1% BPII, 2.4% Subthreshold BPD; M:F = 1:1
- age of onset: teens to 20s usually MDE first, manic episode 6-10 years after average age of first manic episode 32 yr

Risk Factors
- genetic: 60-65% of bipolar patients have family history of major mood disorders, especially bipolar disorders
- clinical features of MDE history favouring bipolar over unipolar diagnosis: early age of onset (<25 yr), increased number of MDEs, psychotic symptoms, postpartum onset, anxiety disorders (especially separat on, panic), antidepressant failure due to early “poop out” or hypomanic symptoms, early impulsivity and aggression, substance abuse, cyclothymic temperament

Selective Serotonin Reuptake Inhibitors in Pregnancy and Infant Outcomes

Paediatr Child Health 2011;16:562-563
Canadian Pediatric Society (CPS) clinical practice guideline recommendations: It is important to treat depression in pregnancy. There is no evidence that SSRIs increase the risk of major malformations. There is conflicting evidence concerning the association of paroxetine and cardiac malformations. SSRIs are not contraindicated while breast-feeding.

Bipolar II is quite often missed and many patients are symptomatic for up to a decade before accurate diagnosis and treatment

Patients with bipolar disorder are at higher risk for suicide when they switch from mania to depression, especially as they become aware of consequences of their behaviour during the manic episode
Treatment
- **lifestyle:** psychoeducation regarding cycling nature of illness, ensure regular check ins, develop early warning system, “emergency plan” for manic episodes, promote stable routine (sleep, meals, exercise)
- **biological:** lithium, anticonvulsants, antipsychotics, ECT (if refractory); monotherapy with antidepressants should be avoided
  - mood stabilizers vary in their ability to “treat” (reduce symptoms acutely) or “stabilize” (prevent relapse and recurrence) manic and depressive symptoms; multi-agent therapy is common
  - treating mania: lithium, valproate, carbamazepine (2nd line), SGA, ECT, benzodiazepines (for acute agitation)
  - preventing mania: same as above but usually at lower dosages, minus benzodiazepines
  - treating depression: lithium, lurisdione, quetiapine, lamotrigine, antidepressants (only with mood stabilizer), ECT
  - preventing depression: same as above plus aripiprazole, valproate (note: quetiapine first line in treating bipolar II depression)
  - mixed episode or rapid cycling: multi-agent therapy, lithium or valproate + SGA (lurisdione, aripiprazole, olanzapine)
- **psychological:** supportive psychotherapy, CBT, IPT or interpersonal social rhythm therapy, family therapy
- **social:** vocational rehabilitation, consider leave of absence from school/work, assess capacity to manage finances, drug and ETOH cessation, sleep hygiene, social skills training, education and recruitment of family members

Course and Prognosis
- high suicide rate (15% mortality from suicide), especially in mixed states
- BP I and II are chronic conditions with a relapsing course featuring alternating manic and depressive episodes; depressive symptoms tend to occur more frequently and last longer than manic episodes
- can achieve high level of functioning between episodes
- may switch rapidly between depression and mania without any period of euthymia in between
- high recurrence rate for mania – 90% will have a subsequent episode in the next 5 yr
- long term follow-up of BP I – 15% well, 45% well with relapses, 30% partial remission, 10% chronically ill

**CYCLOTHYMIA**
Adapted/summarized from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

**Diagnosis**
- presence of numerous periods of hypomanic and depressive symptoms (not meeting criteria for full hypomanic episode or MDE) for ≥2 yr; never without symptoms for ≥2 mo
- never have met criteria for MDE, manic or hypomanic episodes
  - symptoms not better explained by any psychotic disorder (including schizoaffective, schizophrenia, schizoaffectiveform, delusional disorder, or other specified/unspecified)
  - symptoms are not due to the direct physiological effects of a substance or GMC
- symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning

**Treatment**
similar to Bipolar I: mood stabilizer ± psychotherapy, avoid antidepressant monotherapy, treat any comorbid substance use disorder

---

**Anxiety Disorders**

**Definition**
- anxiety is a universal human characteristic involving tension, apprehension, or even terror which serves as an adaptive mechanism to warn about an external threat
- manifestations of anxiety are a result of the activation of the sympathetic nervous system and can be described through P:
  - **physiology:** main brain structure involved is the amygdala (fear conditioning); neurotransmitters involved include 5-HT, cholecystokinin, epinephrine, norepinephrine, DA
  - **psychology:** one’s perception of a given situation is distorted which causes one to believe it is threatening in some way
  - **behaviour:** once feeling threatened, one responds by escaping or facing the situation, thereby causing a disruption in daily functioning
- anxiety becomes pathological when:
  - fear is greatly out of proportion to risk/severity of threat
  - response continues beyond existence of threat or becomes generalized to other similar or dissimilar situations
  - social or occupational functioning is impaired
  - often comorbid with substance use and depression

---

**Lithium** is among few agents with proven efficacy in preventing suicide attempts and completions

**Monotherapy with antidepressants should be avoided in patients with bipolar depression as patients can switch from depression into mania**

**The 4 L's or Bipolar Depression**
Lithium, Lamotrigine, Lurasidone, SeroqueL

**A Randomized Controlled Trial of Cognitive Therapy for Bipolar Disorder: Focus on Long-Term Change**
*J Clin Psychiatry* 2006;67:277-286

**Purpose:** To evaluate long-term change with cognitive therapy plus emotive techniques for the treatment of bipolar disorder.

**Methods:** Blinded RCT including patients with DSM-IV bipolar I or II disorder allocated to either a 6 mo trial of cognitive therapy (CT) with emotive techniques or treatment as usual. Both groups received mood stabilizers. Main outcomes were relapse rates, dysfunctional attitudes, psychosocial functioning, hopelessness, self-control, and medication adherence. Patients were assessed by independent raters blinded to treatment group.

**Results:** At 6 mo, CT patients experienced fewer depressive symptoms and fewer dysfunctional attitudes. There was a non-significant (p=0.06) trend to greater time to depressive relapse. At 12 mo follow-up, CT patients had lower Young Mania Rating scores and improved behavioral self-control. At 18 mo, CT patients reported less severity of illness.

**Conclusions:** CT appears to provide benefits in the 12 mo after completion of therapy.
Differential Diagnosis

Medical Workup of Anxiety Disorder
- routine screening: physical exam, CBC, thyroid function test, electrolytes, urinalysis, urine drug screening
- additional screening: neurological consultation, chest X-ray ECG, CT head

Panic Disorder

DSM-5 Diagnostic Criteria for Panic Disorder

A. recurrent unexpected panic attacks - a panic attack is an abrupt surge of intense fear or intense discomfort that reaches a peak within minutes, and during which time four (or more) of the following symptoms occur
- palpitations, pounding heart, or accelerated heart rate
- sweating
- trembling or shaking
- sensations of shortness of breath or smothering
- feelings of choking
- chest pain or discomfort
- nausea or abdominal distress
- feeling dizzy, unsteady, light-headed, or faint
- chills or heat sensations
- paresthesias (numbness or tingling sensations)
- derealization (feelings of unreality) or depersonalization (being detached from oneself)
- fear of losing control or “going crazy”
- fear of dying

B. 1 mo (or more) of “anxiety about panic attacks” - at least one of the attacks has been followed by one or both of the following:
- persistent concern or worry about additional panic attacks or their consequences
- a significant maladaptive change in behaviour related to the attacks

C. the disturbance is not attributable to the physiological effects of a substance or another medical condition

D. the disturbance is not better explained by another mental disorder

Epidemiology
- prevalence: 2-5% (one of the top five most common reasons to see a family doctor); M:F = 1:2-3
- onset: average early-mid 20s, familial pattern

Treatment
- psychological
  - CBT: interoceptive exposure (eliciting symptoms of a panic attack and learning to tolerate the symptoms without coping strategies); cognitive restructuring (addressing underlying beliefs regarding the panic attacks), relaxation techniques (visualization, box-breathing)
- pharmacological
  - SSRIs: fluoxetine, citalopram, paroxetine, fluvoxamine, sertraline
  - SNRI: venlafaxine
  - with SSRIs/SNRIs, start with low doses, titrate up slowly
  - anxiety disorders often require treatment at higher doses for a longer period of time than depression (i.e. full response may take up to 12 wk)
  - treat for up to 1 year after symptoms resolve to avoid relapse
  - to prevent non-compliance due to physical side effects, explain symptoms to expect prior to initiation of therapy
  - other antidepressants (mirtazapine, MAOIs)
  - consider avoiding buproprion or TCAs due to stimulating effects (exacerbate anxious symptoms)
  - benzodiazepines (short-term, low dose, regular schedule, long half-life, avoid prn usage)

Starting Medication for Anxiety
- start low, go slow, aim high and explain symptoms to expect prior to initiation of therapy to prevent non-compliance due to physical side effects

Prognosis
- 6-10 yr post-treatment: 30% well, 40-50% improved, 20-30% no change or worse
- clinical course: chronic, but episodic with psychosocial stressors
Agoraphobia

DSM-5 Diagnostic Criteria for Agoraphobia
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. marked fear or anxiety about two (or more) of the following five situations:
   - using public transportation
   - being in open spaces
   - being in enclosed places
   - standing in line or being in a crowd
   - being outside of the home alone
B. the individual fears or avoids these situations because of thoughts that escape might be difficult or help might not be available in the event of developing panic-like symptoms or other incapacitating or embarrassing symptoms
C. the agoraphobic situations almost always provoke fear or anxiety
D. the agoraphobic situations are actively avoided, require the presence of a companion, or are endured with intense fear or anxiety
E. the fear or anxiety is out of proportion to the actual danger posed by the agoraphobic situations and to the sociocultural context
F. the fear, anxiety, or avoidance is persistent, typically lasting ≥6 mo
G. the fear, anxiety, or avoidance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning
H. if another medical condition is present, the fear, anxiety, or avoidance is clearly excessive
I. the fear, anxiety, or avoidance is not better explained by the symptoms of another mental disorder and are not related exclusively to obsessions, perceived defects or flaws in physical appearance, reminders of traumatic events, or fear of separation

Note: agoraphobia is diagnosed irrespective of the presence of panic disorder. If an individual's presentation meets criteria for panic disorder and agoraphobia, both diagnoses should be assigned

Treatment
- as per panic disorder

Generalized Anxiety Disorder

DSM-5 Diagnostic Criteria for Generalized Anxiety Disorder
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. excessive anxiety and worry (apprehensive expectation), occurring more days than not for at least 6 mo, about a number of events or activities (such as work or school performance)
B. the individual finds it difficult to control the worry
C. the anxiety and worry are associated with three (or more) of the following six symptoms (with at least some symptoms having been present for more days than not for the past 6 mo)
   1. restlessness or feeling keyed up or on edge
   2. being easily fatigued
   3. difficulty concentrating or mind going blank
   4. irritability
   5. muscle tension
   6. sleep disturbance (difficulty falling or staying asleep, or restless, unsatisfying sleep)
D. the anxiety, worry, or physical symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning
E. the disturbance is not attributable to the physiological effects of a substance or another medical condition
F. the disturbance is not better explained by another mental disorder

Epidemiology
- 1 yr prevalence: 3-8%; M:F = 1:2
- if considering only those receiving inpatient treatment, ratio is 1:1
- most commonly presents in early adulthood

Treatment
- lifestyle: caffeine and EtOH avoidance, sleep hygiene
- psychological: CBT including relaxation techniques, mindfulness
- biological
   - SSRIs and SNRIs are 1st line (paroxetine, escitalopram, sertraline, venlafaxine XL)
   - 2nd line: buspirone (tid dosing), bupropion (caution due to stimulating effects),
   - add-on benzodiazepines (short-term, low dose, regular schedule, long half-life, avoid prn usage)
   - β-blockers not recommended

Prognosis
- chronically anxious adults become less so with age
- depends on pre-morbid personality functioning, stability of relationships, work, and severity of environmental stress
- difficult to treat
**Phobic Disorders**

Adopted/summarized from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013 American Psychiatric Association

**Specific Phobia**
- definition: marked and persistent (>6 mo) fear that is excessive or unreasonable, cued by presence or anticipation of a specific object or situation
- lifetime prevalence 12-16%; M:F ratio variable
- types: animal/insect, environment (heights, storms), blood/injection/injury, situational (airplane, closed spaces), other (loud noise, clowns)

**Social Phobia (Social Anxiety Disorder)**
- definition: marked and persistent (>6 mo) fear of social or performance situations in which one is exposed to unfamiliar people or to possible scrutiny by others; fearing he/she will act in a way that may be humiliating or embarrassing (e.g. public speaking, initiating or maintaining conversation, dating, eating in public)
- 12 mo prevalence rate may be as high as 7%; M:F ratio approximately equal

**Diagnostic Criteria for Phobic Disorders**
- exposure to stimulus almost invariably provokes an immediate anxiety response; may present as a panic attack
- person recognizes fear as excessive or unreasonable
- situations are avoided or endured with anxiety/distress
- significant interference with daily routine, occupational/social functioning, and/or marked distress

**Treatment**
- psychological
  - cognitive behaviour therapy (focusing on both in vivo and virtual exposure therapy, gradually facing feared situations)
  - behavioural therapy is more efficacious than medication
- biological
  - SSRIs/SNRIs (e.g. fluoxetine, paroxetine, sertraline, venlafaxine), MAOIs
  - β-blockers or benzodiazepines in acute situations (e.g. public speaking)

**Prognosis**
- chronic

**Obsessive-Compulsive Disorder**

**DSM-5 Diagnostic Criteria for Obsessive-Compulsive Disorder**
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. presence of obsessions, compulsions, or both
- obsessions are defined by (1) and (2)
  1. recurrent and persistent thoughts, urges, or images that are experienced, at some time during the disturbance, as intrusive and unwanted, and cause marked anxiety or distress in most individuals
  2. the individual attempts to ignore or suppress such thoughts, urges, or images, or to neutralize them with some other thought or action (i.e. by performing a compulsion; see below)
- compulsions are defined by (1) and (2)
  1. repetitive behaviours (e.g. hand washing, ordering, checking) or mental acts (e.g. praying, counting, repeating words silently) that the individual feels driven to perform in response to an obsession or according to rules that must be applied rigidly
  2. behaviours mental acts are aimed at preventing or reducing anxiety or distress, or preventing some dreaded event or situation; however, these behaviours or mental acts are not connected in a realistic way with what they are designed to neutralize or prevent, or are clearly excessive

B. the obsessions or compulsions are time-consuming (e.g. take >1 h/d) or cause clinically significant distress or impairment in social, occupational, or other important areas of functioning

C. the obsessive-compulsive symptoms are not attributable to the physiological effects of a substance or another medical condition

D. the disturbance is not better explained by the symptoms of another mental disorder

**Epidemiology**
- 12 mo prevalence 1.1-1.8%; females affected at slightly higher rates than males
- rate of OCD in first-degree relatives is higher than in the general population

**Treatment**
- CBT: exposure with response prevention (ERP) – involves exposure to feared situations with the addition of preventing the compulsive behaviours; cognitive strategies include challenging underlying beliefs
- pharmacotherapy: SSRIs/SNRIs (12-16 week trials, higher doses vs. depression), clomipramine; adjunctive antipsychotics (risperidone)

**Prognosis**
- tends to be refractory and chronic
### DSM-5 Diagnostic Criteria for Post-Traumatic Stress Disorder

A. exposure to actual or threatened death, serious injury, or sexual violence in one (or more) of the following ways:
   1. directly experiencing the traumatic event(s)
   2. witnessing, in person, the event(s) as it occurred to others
   3. learning that the traumatic event(s) occurred to a close family member or close friend. In cases of actual or threatened death of a family member or friend, the event(s) must have been violent or accidental
   4. experiencing repeated or extreme exposure to aversive details of the traumatic event(s) (e.g. first responders collecting human remains: police officers repeatedly exposed to details of child abuse)

B. presence of one (or more) of the following intrusion symptoms associated with the traumatic event(s), beginning after the traumatic event(s) occurred
   1. recurrent, involuntary, and intrusive distressing memories of the traumatic event(s)
   2. recurrent distressing dreams in which the content and/or affect of the dream are related to the traumatic event(s)
   3. dissociative reactions (e.g. flashbacks) in which the individual feels or acts as if the traumatic event(s) were recurring
   4. intense or prolonged psychological distress at exposure to internal or external cues that symbolize or resemble an aspect of the traumatic event(s)
   5. marked physiological reactions to internal or external cues that symbolize or resemble an aspect of the traumatic event(s)

C. persistent avoidance of stimuli associated with the traumatic event(s), beginning after the traumatic event(s) occurred, as evidenced by one or both of the following
   1. avoidance of or efforts to avoid distressing memories, thoughts, or feelings about or closely associated with the traumatic event(s)
   2. avoidance of or efforts to avoid external reminders (people, places, conversations, activities, objects, situations) that arouse distressing memories, thoughts, or feelings about or closely associated with the traumatic event(s)

D. negative alterations in cognitions and mood associated with the traumatic event(s), beginning or worsening after the traumatic event(s) occurred, as evidenced by two (or more) of the following
   1. inability to remember an important aspect of the traumatic event(s)
   2. persistent and exaggerated negative beliefs or expectations about oneself, others, or the world
   3. persistent, distorted cognitions about the cause or consequences of the traumatic event(s) that lead the individual to blame himself/herself or others
   4. persistent negative emotional state (e.g. fear, horror, anger, guilt, or shame)
   5. markedly diminished interest or participation in significant activities
   6. feelings of detachment or estrangement from others
   7. persistent inability to experience positive emotions

E. marked alterations in arousal and reactivity associated with the traumatic event(s), beginning or worsening after the traumatic event(s) occurred, as evidenced by two (or more) of the following
   1. irritable behaviour and angry outbursts (with little or no provocation) typically expressed as verbal or physical aggression toward people or objects
   2. reckless or self-destructive behaviour
   3. hypervigilance
   4. exaggerated startle response
   5. problems with concentration
   6. sleep disturbance (e.g. difficulty falling or staying asleep or restless sleep)

F. duration of the disturbance (criteria B, C, D, and E) is more than 1 mo

G. the disturbance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning

H. the disturbance is not attributable to the physiological effects of a substance or another medical condition

### Epidemiology

- prevalence of 7% in general population
- men's trauma is most commonly combat experience/physical assault; women's trauma is usually physical or sexual assault

### Treatment

- psychotherapy, CBT
  - ensure safety and stabilize: emotional regulation techniques (e.g. breathing, relaxation)
  - once coping mechanisms established, can explore/mourn trauma - challenge dysfunctional beliefs, etc.
  - reconnect and integrate - exposure therapy, etc.
• biological
  ■ SSRIs (e.g. paroxetine, sertraline)
  ■ prazosin (for treating disturbing dreams and nightmares)
  ■ benzodiazepines (for acute anxiety)
  ■ adjunctive atypical antipsychotics (risperidone, olanzapine)
• eye movement desensitization and reprocessing (EMDR): an experimental method of reprocessing memories of distressing events by recounting them while using a form of dual attention stimulation such as eye movements, bilateral sound, or bilateral tactile stimulation (its use is controversial because of limited evidence)

Complications
• substance abuse, relationship difficulties, depression, impaired social and occupational functioning disorders, personality disorders

Adjustment Disorder

Definition
• a diagnosis encompassing patients who have difficulty coping with a stressful life event or situation and develop acute, often transient, emotional or behavioural symptoms that resemble less severe versions of other psychiatric conditions

DSM 5 Diagnostic Criteria for Adjustment Disorder
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
A. the development of emotional or behavioural symptoms in response to an identifiable stressor(s) occurring within 3 mo of the onset of the stressor(s)
B. these symptoms or behaviours are clinically significant as evidenced by either of the following:
  ■ marked distress that is in excess of what would be expected from exposure to the stressor
  ■ significant impairment in social or occupational (academic) functioning
C. the stress-related disturbance does not meet criteria for another mental disorder and is not merely an exacerbation of a pre-existing mental disorder
D. the symptoms do not represent normal bereavement
E. once the stressor (or its consequences) has terminated, the symptoms do not persist for more than an additional 6 mo
  ■ specifiers: with depressed mood, with anxiety, with mixed anxiety/depression, with conduct disturbance, with mixed disturbance of conduct/emotions unspecified

Classification
• types of stressors
  ■ single (e.g. termination of romantic relationship)
  ■ multiple (e.g. marked business difficulties and marital problems)
  ■ recurrent (e.g. seasonal business crises)
  ■ continuous (e.g. living in a crime-ridden neighbourhood)
  ■ developmental events (e.g. going to school, leaving parental home, getting married, becoming a parent, failing to attain occupational goals, retirement)

Epidemiology
• F:M 2:1, prevalence 2-8% of the population

Treatment
• brief psychotherapy individual or group (particularly useful for patients dealing with unique and specific medical issues; e.g. colostomy or renal dialysis groups), crisis intervention
• biological
  ■ benzodiazepines may be used for those with significant anxiety symptoms (short-term, low-dose, regular schedule)

Bereavement

Clinical Presentation
• bereavement is a normal psychological and emotional reaction to a significant loss, also called grief or mourning
• length and characteristics of “normal” bereavement are variable between individuals/cultures
• normal response: protest → searching and acute anguish → despair and detachment → reorganization
• presence of the following symptoms may indicate abnormal grief/presence of MDD
  ■ guilt about things other than actions taken or not taken by the survivor at the time of death
  ■ thoughts of death other than the survivor feeling that they would be better off dead or should have died with the deceased person; morbid preoccupation with worthlessness
  ■ marked psychomotor retardation; prolonged and marked functional impairment
  ■ hallucinatory experiences other than thinking that the survivor hears the voice of or transiently sees the image of the deceased person
  ■ dysphoria that is pervasive and independent of thoughts or triggers of the deceased, absence of mood reactivity

Risk Factors for Poor Bereavement Outcome
• Poor social supports
• Unanticipated death or lack of preparation for death
• Highly dependent relationship with deceased
• High initial distress
• Other concurrent stresses and losses
• Death of a child
• Pre-existing psychiatric disorders, especially depression and separation anxiety
Neurocognitive Disorders

Delirium

- see Neurology, N20 and Geriatric Medicine, G4

DSM-5 Diagnostic Criteria for Delirium

Repinned with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. attention and awareness: disturbance in attention (i.e. reduced ability to direct, focus, sustain, and shift attention) and awareness (reduced orientation to the environment)

B. acute and fluctuating: disturbance develops over short period of time (usually hours to days), represents a change from baseline attention and awareness, and tends to fluctuate in severity during the course of a day

C. cognitive changes: an additional disturbance in cognition (e.g. memory deficit, disorientation, language, visuospatial ability, or perception)

D. not better explained: disturbances in criteria A and C are not better explained by another neurocognitive disorder (pre-existing, established, or evolving) and do not occur in the context of a severely reduced level of arousal (e.g. coma)

E. direct physiological cause: evidence that disturbance is a direct physiological consequence of another medical condition, substance intoxication or withdrawal (i.e. due to a drug of abuse or medication), toxin, or is due to multiple etiologies

Note: delirium can be described as HYPERactive, HYPOfactive, or MIXED presentation. While patients with hyperactive delirium may demonstrate features of restlessness and agitation, as well as experience hallucinations and delusions, those with hypoactive delirium present with lethargy, sedation and respond slowly to questioning

Clinical Presentation and Assessment

- common symptoms
  - distractibility, disorientation (time, place, rarely person)
  - misinterpretations, illusions, hallucinations
  - speech/language disturbances (dysarthria, dysnomia)
  - affective symptoms (anxiety, fear, depression, irritability, anger, euphoria, apathy)
  - shifts in psychomotor activity (groping/picking at clothes, attempts to get out of bed when unsafe, sudden movements, sluggishness, lethargy)
  - impairment in sleep duration and/or architecture (e.g. sleep-wake reversal)
  - Folstein Mini Mental Status Exam or Montreal Cognitive Assessment are helpful to assess baseline of altered mental state (i.e. score will improve as symptoms resolve)

Risk Factors

- most common precipitating factors include: polypharmacy (particularly involving psychoactive drugs such as anticholinergics), infection, dehydration, immobility, malnutrition, and use of bladder catheters
- other factors include:
  - hospitalization (incidence 10-56%), frail and surgical patients are at the greatest risk
  - previous delirium
  - nursing home residents (incidence 60%)
  - old age (especially males)
  - severe illness (e.g. cancer, AIDS)
  - recent anesthesia or surgery
  - brain vulnerability: substance abuse, past psychiatric illness, pre-existing neurologic or neurocognitive disorder

Investigations

- standard: CBC and differential, electrolytes (including Ca, Mg and PO₄), glucose, BUN, Cr, TSH/T4, LFTs, vit B₆, folate, albumin; urinalysis, urine C+S
- as indicated: ECG (to assess QT interval when considering treatment with an antipsychotic agent), CXR, CT head, toxicology/heavy metal screen, VDRL, HIV, LP blood cultures, EEG (typically abnormal - generalized slowing [most common] or fast activity, can also be used to rule out underlying seizures or post-ictal states as etiology)

Treatment

- support and watchful waiting should be first line, as well as education and normalization of the grief process
- screen for increased alcohol, cigarette and drug use
- normal grief should not be treated with antidepressant or anxiolytic medication, as it is important to allow the person to experience the whole mourning process to achieve resolution
- psychosocial: for those needing additional support, complex grief/bereavement, or significant MDD, grief therapy (individual or group) is indicated
- pharmacotherapy: if MDD present, past history of mood disorders, severe or autonomous symptoms

Neurocognitive Disorders

Etiology of Delirium

- old age
- nursing home residents (incidence 60%)
- hospitalization (incidence 10-56%)
- frail and surgical patients
- hyperactive or hypoactive

Bereavement is associated with a significant increase in morbidity and mortality acutely following the loss, with effects seen up to 1 yr after.

Loneliness is the most common symptom that continues to persist in normal bereavement and may last several years.

Confusion Assessment Method (CAM) for Diagnosis of Delirium

Highly sensitive and specific method to diagnosis delirium
- Part 1: an assessment instrument that screens for overall cognitive impairment
- Part 2: includes four features found best able to distinguish delirium from other cognitive impairments

Need (1) + (2) = (3 or 4)
(1) Acute onset and fluctuating course
(2) Inattention
(3) Disorganized thinking
(4) Altered level of consciousness - hyperactive or hypoactive

Visual hallucinations are organic until proven otherwise

Etiology of Delirium

I WATCH DEATH
- Infectious (encephalitis, meningitis, UTI, pneumonia)
- Withdrawal (alcohol, barbiturates, benzodiazepines)
- Acute metabolic disorder (electrolyte imbalance, hepatic or renal failure)
- Trauma (head injury, post-operative)
- CNS pathology (stroke, hemorhage, tumour, seizure disorder, Parkinson’s)
- Hypoxia (anemia, cardiac failure, pulmonary embolus)
- Deficiencies (vitamin B₁₂, folic acid, thiamine)
- Endocrinopathies (thyroid, glucose, parathyroid, adrenal)
- Acute vascular (shock, vasculitis, hypertensive encephalopathy)
- Toxins: substance use sedatives, opioids (especially morphine), anesthetics, anticholinergics anticonvulsants, dopaminergic agents, steroids, insulin, glyburide, antibiotics (especially quinolones), NSAIDs
- Heavy metals (arsenic, lead, mercury)
indications for CT head: focal neurological deficit, acute change in status, anticoagulant use, acute incontinence, gait abnormality, history of cancer

MRI may be useful to exclude acute or subacute stroke and multifocal inflammatory lesions in patients with delirium of unknown cause and negative head CT

Management
- identify and manage underlying cause
- identify and treat underlying cause immediately
- stop all non-essential medications
- maintain nutrition, hydration, electrolyte balance and monitor vitals
- optimize the environment
  - environment: quiet, well-lit, near window for cues regarding time of day
  - optimize hearing and vision
  - room near nursing station for closer observation; constant care if patient jumping out of bed, pulling out lines
  - family member present for reassurance and re-orientation
- frequent orientation - calendar, clock, reminders
- pharmacotherapy
  - low dose, high potency antipsychotics: haloperidol has the most evidence; reasonable alternatives include risperidone, olanzapine (more sedating, less QT prolongation), quetiapine (if EPS), aripiprazole (may shorten QTc)
  - benzodiazepines only to be used in alcohol/substance withdrawal delirium; otherwise, can worsen delirium (antipsychotics will not be useful in substance withdrawal delirium)
- try to minimize anticholinergic side effects
- physical restraints to maintain safety only if necessary (last resort)

Prognosis
- up to 50% 1 yr mortality rate after episode of delirium

Major Neurocognitive Disorder (Dementia)

see Neurology: N21

DSM-5 Diagnostic Criteria for Major Neurocognitive Disorder
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. evidence of significant cognitive decline from a previous level of performance in one or more cognitive domains (complex attention, executive function, learning and memory, language, perceptual-motor, or social cognition) based on:
  1. concern of the individual, a knowledgeable informant, or the clinician that there has been a significant decline in cognitive function;
  and
  2. substantial impairment in cognitive performance, preferably documented by standardized neuropsychological testing or, in its absence, another quantified clinical assessment

B. cognitive deficits interfere with independence in everyday activities (i.e. at a minimum, requiring assistance with complex instrumental activities of daily living such as paying bills or managing medications)
- Note: if deficits do not interfere as in B, and impairments are mild-moderate as in A, this is considered "mild neurocognitive disorder"; see Neurology: N21

C. cognitive deficits do not occur exclusively in the context of a delirium

D. cognitive deficits are not better explained by another mental disorder (e.g. major depressive disorder, schizophrenia)

E. in the case of neurodegenerative dementias such as Alzheimer's Disease, disturbances should be of insidious onset and progressive

Specify whether due to:

</tbody>
</table>

Epidemiology
- prevalence increases with age: 5% in patients >65 yr of age; 35-50% in patients >85 yr of age
- pre-test probability of dementia in an older person with reported memory loss is estimated to be 60%
- prevalence is increased in people with Down's syndrome and head trauma
- Alzheimer's disease comprises >50% of cases; vascular causes comprise approximately 15% of cases (other causes of dementia neurocognitive disorder – see Neurology: N23)
- average duration of illness from onset of symptoms to death is 8-10 yr

Subtypes
- with or without behavioural disturbance (e.g. wandering, agitation)
- early-onset: age of onset <65 yr
- late-onset: age of onset >65 yr
Investigations (rule out reversible causes)
- standard: see Delirium, PS19
- as indicated: VDRL, HIV, SPECT, CT head in dementia
- indications for CT head: same as for delirium, plus: age <60, rapid onset (unexplained decline in cognition or function over 1-2 mo), dementia of relatively short duration (<2 yr), recent significant head trauma, unexplained neurological symptoms (new onset of severe headache/seizures)

Management
- see Neurology, N20 for further management
- treat underlying medical problems and prevent others
- provide orientation cues for patient (e.g. clock, calendar)
- provide education and support for patient and family (e.g. day programs, respite care, support groups, home care)
- consider long-term care plan (nursing home) and power of attorney/living will
- inform Ministry of Transportation about patient's inability to drive safely
- consider pharmacological therapy
  - cholinesterase inhibitors (e.g. donepezil [Aricept®], rivastigmine, galantamine) for mild to severe disease
  - NMDA receptor antagonist (e.g. memantine) for moderate to severe disease
  - low-dose neuroleptics (e.g. risperidone, quetiapine), antidepressants or trazodone if behavioural or emotional symptoms prominent – start low and go slow
  - reassess pharmacological therapy every 3 mo

Overview
- a neurobiological disorder involving compulsive drug seeking and drug taking, despite adverse consequences, with loss of control over drug use (think issues with the “3 Cs”: compulsive, consequences, control)
- dependence is the hallmark of substance use disorders and comes in the following forms:
  - behavioural: substance-seeking activities and pathological use patterns
  - physical: physiologic withdrawal effects without use
  - psychological: continuous or intermittent cravings for the substance to avoid dysphoria or attain drug state
- abuse: drug use that deviates from the approved social or medical pattern, usually causing impairment or disruption to function in self or others
- these disorders are usually chronic with a relapsing and remitting course

Epidemiology
- 47% of those with substance abuse have mental health problems
- 29% of those with a mental health disorder have a substance use disorder
- 47% of those with schizophrenia and 25% of those with an anxiety disorder have a substance use disorder
Etiology
- almost all drugs (and activities) of abuse increase dopamine in the nucleus accumbens, an action that contributes to their euphoric properties and, with repeated use, to their ability to change signalling pathways in the brain's reward system
- substance use disorders arise from multifactorial interactions between genes (personality, neurobiology) and environment (low socioeconomic status, substance-using peers, abuse history, chronic stress)

Diagnosis
- substance use disorders are measured on a continuum from mild to severe based on the number of criteria met within 12 mo
  - mild: 2-3
  - moderate: 4-5
  - severe: 6 or more
- each specific substance is addressed as a separate use disorder and diagnosed utilizing the same overarching criteria (e.g. a single patient may have moderate alcohol use disorder, and a mild stimulant use disorder)
- testing for illicit drugs is most commonly done on urine or blood samples; Serum toxicology screen is needed to assess alcohol level
- criteria for substance use disorders (PEC WITH MCAT)
  - use despite Physical or psychological problem (e.g. alcoholic liver disease or cocaine related nasal problems)
  - failures in important External roles at work/school/home
  - Craving or a strong desire to use substance
  - Withdrawal
  - continued use despite Interpersonal problems
  - Tolerance, needing to use more substance to get same effect
  - use in physically Hazardous situations
  - More substance used or for longer period than intended
  - unsuccessful attempts to Cut down
  - Activities given up due to substance
  - excessive Time spent on using or finding substance

Classification of Substances

<table>
<thead>
<tr>

<td>LSD, mescaline, psilocybin, PCP, ketamine, ibogaine, salvia</td>
<td>Distortion of sensory stimuli and enhancement of feelings, psychosis (+++ visual hallucinations), delirium, anxiety (panic), poor coordination</td>
</tr>
</tbody>
</table>

General Approach to Assessment
- ask about socially accepted substances (e.g. nicotine, alcohol) before asking about use of marijuana, misuse of prescription medicines, and about illicit drugs
- obtaining history from family members may be helpful

General Approach to Treatment
- approach must be appropriate to the patient's current state of change (see Population Health and Epidemiology, Health Promotion Strategies, PH6, for Prochaska’s Stages of Change Model)
- patients will only change when the pain of change appears less than the pain of staying the same
- provider can help by providing psychoeducation (emphasize neurobiologic model of addiction), motivation, and hope
- principles of motivational interviewing (see Psychotherapy, PS40)
  - non-judgmental stance
  - space for patient to talk and reflect
  - offer accurate empathic reflections back to patient to help frame issue
  - encourage and offer referral to evidence based services
  - social: 12-step programs (alcoholics anonymous, narcotics anonymous), family education and support
  - psychological therapy: addiction counselling, motivational enhancement therapy (MET), CBT, contingency management, group therapy, family therapy, marital counselling
  - medical management (differs depending on substance): acute detoxification, pharmacologic agents to aid maintenance
  - harm reduction whenever possible: safe-sex practices, avoid driving while intoxicated, avoid substances with child care, safe needle practices/exchange, pill-testing kits, reducing tobacco use
  - comorbid psychiatric conditions: many will resolve with successful treatment of the substance use disorder but patients who meet full criteria for another disorder should be treated for that disorder with psychological and pharmacologic therapies

Questions to Characterize Substance Use and Risk Assessment
- When was the last time you used?
- How long can you go without using?
- By what route (oral ingestion, insufflation, smoking, IV) do you usually use?
- Are there any triggers that you know will cause you to use?
- How has your substance use affected your work, school, relationships?
- Substances can be very expensive, how do you support your drug use?
- Have you experienced medical or legal consequences of your use?
- Any previous attempts to cut down or quit, and did you experience any withdrawal symptoms?
Nicotine

- see Family Medicine, FM11

Alcohol

- see Family Medicine, FM12 and Emergency Medicine, ER54

History

- CAGE: validated screening questionnaire
  - C ever felt the need to Cut down on drinking?
  - A ever felt Annoyed at criticism of your drinking?
  - G ever feel Guilty about your drinking?
  - E ever need a drink first thing in morning (Eye opener)?
    - for men, a score of ≥2 is a positive screen; for women, a score of ≥1 is a positive screen
    - if positive CAGE, then assess further to distinguish between problem drinking and alcohol use disorder

<table>
<thead>
<tr>
<th>Table 4. Canada’s Low-Risk Alcohol Drinking Guidelines</th>
</tr>
</thead>
<tbody>
<tr>
<td>Moderate Drinking</td>
</tr>
<tr>
<td>Men: 3 or less/d (≤15/wk)</td>
</tr>
<tr>
<td>Women: 2 or less/d (≤10/wk)</td>
</tr>
<tr>
<td>Elderly: 1 or less/d</td>
</tr>
</tbody>
</table>

Alcohol Intoxication

- legal limit for impaired driving is 10.6 mmol/L (50 mg/dL) reached by 2-3 drinks/h for men and 1-2 drinks/h for women
- coma can occur with >60 mmol/L (non-tolerant drinkers) and 90-120 mmol/L (tolerant drinkers)

Alcohol Withdrawal

- occurs within 12-48 h after prolonged heavy drinking and can be life-threatening
- alcohol withdrawal can be described as having 4 stages, however not all stages may be experienced:
  - stage 1 (onset 12-18 h after last drink): “the shakes” tremor, sweating, agitation, anorexia, cramps, diaphoresis, sleep disturbance
  - stage 2 (onset 7-48 h): alcohol withdrawal seizures, usually tonic-clonic, non-focal and brief
  - stage 3 (onset 48 h): visual, auditory, olfactory or tactile hallucinations
  - stage 4 (onset 3-5 d): delirium tremens, confusion, delusions, hallucinations, agitation, tremors, autonomic hyperactivity (fever, tachycardia, HTN)
- course: almost completely reversible in young; elderly often left with cognitive deficits
- mortality rate 20% if untreated

Management of Alcohol Withdrawal

- monitor using the Clinical Institute Withdrawal Assessment for Alcohol (CIWA-A) scoring system
  - areas of assessment include:
    - physical (5): nausea and vomiting, tremor, agitation, paroxysmal sweats, headache/fullness in head
    - psychological/cognitive (2): anxiety, orientation/clouding of sensorium
    - perceptual (3): tactile disturbances, auditory disturbances, visual disturbances
  - all categories are scored from 0-7 (except: orientation/sensorium 0-4), maximum score of 67
  - mild <10, moderate 10-20, severe >20

<table>
<thead>
<tr>

<tr>
<td>Diazepam 20 mg x 3 doses as seizure prophylaxis (haloperidol lowers seizure threshold)</td>
</tr>
<tr>
<td>Admit to Hospital if</td>
</tr>
<tr>
<td>Still in withdrawal after &gt;80 mg of diazepam</td>
</tr>
<tr>
<td>Delirium tremens, recurrent arrhythmias, or multiple seizures</td>
</tr>
<tr>
<td>Medically ill or unsafe to discharge home</td>
</tr>
</tbody>
</table>

Delirium Tremens (alcohol withdrawal delirium)

- Autonomic hyperactivity (diaphoresis, tachycardia, increased respiration)
- Hand tremor
- Insomnia
- Psychomotor agitation
- Anxiety
- Nausea or vomiting
- Tonic-clonic seizures
- Visual/tactile/auditory hallucinations
- Persecutory delusions

Confabulations: the fabrication of imaginary experiences to compensate for memory loss

Make sure to ask about other alcohols: mouthwash, rubbing alcohol, methanol, ethylene glycol, aftershave (may be used as a cheaper alternative)

A “Standard Drink”

| Spirit (40%): 1.5 oz. or 43 mL |
| Table Wine (12%): 5 oz. or 142 mL |
| Fortified Wine (18%): 3 oz. or 85 mL |
| Regular Beer (5%): 12 oz. or 341 mL |
| OR |
| 1 pint of beer = 1.5 SD |
| 1 bottle of wine = 5 SD |
| 1 “mickey” = 8 SD (375 ml) |
| "26-e-" = 17 SD (750 ml) |
| "40 oz. = 27 SD |

Treatment of Opioid Use Disorder

- **Wernicke-Korsakoff Syndrome**
  - alcohol-induced amnestic disorders due to thiamine deficiency
  - necrotic lesions: mammillary bodies, thalamus, brainstem
  - Wernicke's encephalopathy (acute and reversible): triad of oculomotor dysfunction such as nystagmus (CN VI palsy), gait ataxia, and confusion
  - Korsakoff's syndrome (chronic and only 20% reversible with treatment): anterograde amnesia and confabulations; cannot occur during an acute delirium or dementia and must persist beyond usual duration of intoxication/withdrawal
  - management
    - Wernicke's: thiamine 100 mg PO OD x 1-2 wk
    - Korsakoff's: thiamine 100 mg PO bid/tid x 3-12 mo

- **Treatment of Alcohol Use Disorder**

  - **see General Approach to Treatment, PS4**
  - **pharmacological**
    - naltrexone (Revia®): opioid antagonist, shown to be successful in reducing the "high" associated with alcohol, moderately effective in reducing cravings, frequency or intensity of alcohol binges
    - disulfiram (Antabuse®): prevents oxidation of alcohol (blocks acetaldehyde dehydrogenase); with alcohol consumption, acetaldehyde accumulates to cause a toxic reaction (vomiting, tachycardia, death); if patient relapses, must wait 48 h before restarting Antabuse®; prescribed only when treatment goal is abstinence. RCT evidence is generally poor or negative
    - acamprosate (Campral®): NMDA glutamate receptor antagonist; useful in maintaining abstinence and decreasing cravings

- **Opioids**

  - types of opioids: heroin, morphine, oxycodone, Tylenol #3® (codeine), hydromorphone, fentanyl
  - major risks associated with the use of contaminated needles: increased risk of hepatitis B and C, bacterial endocarditis, HIV/AIDS

- **Acute Intoxication**

  - direct effect on receptors in CNS resulting in decreased pain perception, sedation, decreased sex drive, nausea/vomiting, decreased GI motility (constipation and anorexia), and respiratory depression

- **Toxic Reaction**

  - typical syndrome includes shallow respirations, miosis, bradycardia, hypothermia, decreased level of consciousness
  - management
    - ABCs
    - IV glucose
    - naloxone hydrochloride (Narcan®): 0.4 mg up to 2 mg IV for diagnosis
    - treatment: intubation and mechanical ventilation, ± naloxone drip, until patient alert without naloxone (up to >48 h with long-acting opioids)
  - caution with longer half-life; may need to observe for toxic reaction for at least 24 h

- **Withdrawal**

  - symptoms: depression, insomnia, drug-craving, myalgias, nausea, chills, autonomic instability (lacrimation, rhinorrhea, piloerection)
  - onset: 6-12 h; duration: 5-10 d
  - complications: loss of tolerance (overdose on relapse), miscarriage, premature labour
  - management: long-acting oral opioids (methadone, buprenorphine), α-adrenergic agonists (clonidine)

- **Treatment of Opioid Use Disorder**

  - long term treatment may include withdrawal maintenance treatment with methadone (opioid agonist) or buprenorphine (mixed agonist-antagonist)
  - Suboxone® formulation includes naloxone in addition to buprenorphine, in an effort to prevent injection of the drug. When naloxone is injected, it will precipitate opiate withdrawal and block the opiate effect of buprenorphine; however, it will not have this antagonist action when taken sublingually

- **Cocaine**

  - street names: blow, C, coke, crack, flake, freebase, rock, snow
  - alkaloid extracted from leaves of the coca plant; blocks presynaptic uptake of serotonin (causing euphoria), dopamine (linked to its addictive effect), norepinephrine and epinephrine (causing vasoconstriction, HTN)
  - sodium channel blockade - cocaine slows or blocks nerve conduction and acts as a local anesthetic by altering recovery of neuronal Na+ channels. It has a similar effect on cardiac Na+ channels and in overdose can manifest on ECG as prolongation of the QRS complex
  - self-administered by inhalation (90% bioavailability), insufflation (e.g. intranasal; 80% bioavailability), or intravenous route
Substance-Related and Addictive Disorders

- onset and duration of action: onset within seconds if inhaled, lasting 15-30 min; onset in 3-5 min if insufflated, blood levels peak at 10-20 min with effects beginning to fade after 45-60 min. Cocaine has a biologic half life of 1 h, thus repeated self-administration is common among users to maintain an effect

Intoxication
- elation, euphoria, pressured speech, restlessness, sympathetic stimulation (e.g. tachycardia, mydriasis, sweating)
- prolonged use may result in paranoia and psychosis

Overdose
- medical emergency: HTN, tachycardia, tonic-clonic seizures, dyspnea, and ventricular arrhythmias
- treatment with IV diazepam to control seizures
- beta-blockers (incl. labetalol or propranolol) are not recommended because of risk from unopposed alpha-adrenergic stimulation

Withdrawal
- initial “crash” (1-48 h): increased sleep, increased appetite
- withdrawal (1-10 wk): dysphoric mood plus fatigue, irritability, vivid unpleasant dreams, insomnia or hypersomnia, psychomotor agitation or retardation
- complications: relapse, suicide (significant increase in suicide during withdrawal period)
- management: supportive management

Treatment of Cocaine Use Disorder
- see General Approach to Treatment, PS4
- no pharmacologic agents have widespread evidence or acceptance of use

Complications
- cardiovascular: arrhythmias, MI, CVA, ruptured AAA, chest pain (accounts for 40% of all cocaine-related ED visits)
- neurologic: seizures
- psychiatric: psychosis, paranoia, delirium, suicidal ideation
- other: nasal septal deterioration, acute/chronic lung injury “crack lung”, possible increased risk of connective tissue disease

Amphetamines
- includes prescription medications for ADHD such as Ritalin® and Adderall®
- intoxication characterized by euphoria, improved concentration, sympathetic and behavioural hyperactivity and at high doses can mimic psychotic mania, can eventually cause coma
- chronic use can produce a paranoid psychosis which can resemble schizophrenia with agitation, paranoia, delusions and hallucinations
- withdrawal symptoms include dysphoria, fatigue, and restlessness
- treatment of amphetamine induced psychosis: antipsychotics for acute presentation, benzodiazepines for agitation, β-blockers for tachycardia, hypertension

Cannabis
- cannabis (marijuana) is the most commonly used recreational drug
- psychoactive substance: delta-9-tetrahydrocannabinol (Δ9-THC)
- general clinical manifestations: intoxication characterized by tachycardia, conjunctival vascular engorgement, dry mouth, altered sensorium, increased appetite, and muscle relaxation
- neuropsychiatric effects:
  - altered mood, perception and thought content: increased sense of well-being, euphoria/laughter
  - impaired cognitive and psychomotor performance: reduced reaction time, impaired attention, concentration and short-term memory.
  - It may also impair motor coordination required to complete complex tasks requiring divided attention. Notably, psychomotor impairments may interfere with one’s ability to operate heavy machinery such as automobiles
-inhaled marijuana: onset of psychoactive effects occurs rapidly with peak effects felt 15-30 min after intake and lasting up to 4 h
- acute exacerbation in patients with asthma may be a complication with inhalation
- ingested marijuana: following oral ingestion, psychotrophic effects set in with a delay of 30-90 min, reach their maximum after 2-3 h and last for about 4-12 h, depending on dose (Grottenhrenen, 2003, pharmacokinetics and pharmacodynamics of cannabinoids)
- high doses can cause depersonalization, paranoia, anxiety and may trigger psychosis and schizophrenia if predisposed
- chronic use is associated with tolerance and an apathetic, amotivational state, and increases risk of later manic episodes
- assessment: standard urine drug screens
- treatment of cannabis use disorder: see General Approach to Treatment, PS4
- cessation following heavy use produces a significant withdrawal syndrome: irritability, anxiety, insomnia, decreased food intake
Hallucinogens

- Types of hallucinogens by primary action:
  - 5-HT2A agonists: LSD, mescaline (peyote), psilocybin mushrooms, DMT (ayahuasca)
  - NMDA antagonists: PCP, ketamine
  - K-opioid agonists: salvinorin A, ibogaine
- 5-HT2A agonists are most commonly used; intoxication characterized by tachycardia, HTN, mydriasis, tremor, hyperpyrexia, and a variety of perceptual, mood and cognitive changes (rarely, if ever, deadly; treat with diazepam symptomatically)
- Psychological effects of high doses: depersonalization, derealization, paranoia, and anxiety (panic with agoraphobia)
- Tolerance develops rapidly (hours-days) to most hallucinogens so physical dependency is virtually impossible, although psychological dependency and problematic usage patterns can still occur
- No specific withdrawal syndrome characterized
- Management of acute intoxication
- Support, reassurance, diminished stimulation; benzodiazepines or high potency antipsychotics seldom required (if used, use small doses), minimize use of restraints
- Long term adverse effects: controversial role in triggering psychiatric disorders, particularly mood or psychosis, thought to be chiefly in genetic with other risk factors
- Hallucinogen Persisting Perception Disorder: DSM-5 diagnosis characterized by long lasting, spontaneous, intermittent recurrences of visual perceptual changes reminiscent of those experienced with hallucinogen exposure

"Club Drugs"

Table 6. The Mechanism and Effects of Common "Club Drugs"

<table>
<thead>
<tr>
<th>Drug</th>
<th>Mechanism</th>
<th>Effect</th>
<th>Adverse Effects</th>
</tr>
</thead>
<tbody>
<tr>
<td>MDMA (&quot;Ecstasy&quot;, &quot;X&quot;, &quot;E&quot;, &quot;M&quot;, &quot;Molly&quot;)</td>
<td>Acts on serotonergic and dopaminergic pathways, properties of a hallucinogen and stimulant</td>
<td>Enhanced sensorium; feelings of well-being, empathy</td>
<td>Sweating, tachycardia fatigue, muscle spasms (especially jaw clenching), ataxia, hyperpyrexia, arrhythmias, DIC, rhabdomyolysis, renal failure, seizures, death</td>
</tr>
<tr>
<td>Gamma Hydroxybutyrate (GHB, &quot;G&quot;, &quot;Liquid Ecstasy&quot;)</td>
<td>Biphasic dopamine response (inhibition then release) and releases opiate-like substance</td>
<td>Euphoric effects, increased aggression, impaired judgment</td>
<td>Sweating, tachycardia, fatigue, muscle spasms (especially jaw clenching), ataxia, severe withdrawal from abrupt cessation of high doses: tremor, seizures, psychosis</td>
</tr>
<tr>
<td>Flunitrazepam (Rohypnol® &quot;Roofies&quot;, &quot;Rope&quot;, &quot;The Forget Pill&quot;)</td>
<td>Potent benzodiazepine rapid oral absorption</td>
<td>Sedation, psychomotor impairment, amnestic effects, decreased sexual inhibition</td>
<td>CNS depression with EtOH</td>
</tr>
<tr>
<td>Ketamine (&quot;Special K&quot;, &quot;K-Kkat&quot;)</td>
<td>NMDA receptor antagonist, rapid-acting general anesthetic used in pediatrics and by veterinarians</td>
<td>&quot;Dissociative&quot; state, profound amnesia/ analgesia, hallucinations and sympathomimetic effects</td>
<td>Psychological distress, accidents due to intensity of experience and lack of bodily control. In overdose: decreased LOC, respiratory depression, catatonia</td>
</tr>
<tr>
<td>Methamphetamine (&quot;speed&quot;, &quot;meth&quot;, &quot;chalk&quot;, &quot;ice&quot;, &quot;crystal&quot;)</td>
<td>Amphetamine stimulant, induces noradrenaline, dopamine, and serotonin release</td>
<td>Rush begins in min, effects last 6-8 h, increased activity, decreased appetite, general sense of well-being, tolerance occurs quickly, users often binge and crash</td>
<td>Short-term use: high agitation, rage, violent behaviour, occasionally hyperthermia and convulsions. Long-term use: addiction, anxiety, confusion, insomnia, paranoia, auditory and tactile hallucinations (especially formication), delusions mood disturbance, suicidal and homicidal thoughts, stroke. May be contaminated with lead, and IV users may present with acute lead poisoning</td>
</tr>
<tr>
<td>Phencyclidine (&quot;PCP&quot;, &quot;angel dust&quot;)</td>
<td>Not understood, used by veterinarians to immobilize large animals</td>
<td>Amnestic, euphoric, hallucinatory state</td>
<td>Horizontal/vertical myostagmus, myoclonus, ataxia, autonomic instability (treat with diazepam IV), prolonged agitation psychosis (treat with haloperidol); high risk for suicide; violence towards others. High dose can cause coma</td>
</tr>

</table>

Cannabis Use and Risk of Psychotic or Affective Mental Health Outcomes: A Systematic Review

The Lancet 2007;370:319-328

Purpose: To review the evidence for cannabis use and occurrence of psychotic or affective mental health outcomes.

Study Characteristics: A meta-analysis of 35 population-based longitudinal studies, or case-control studies nested within longitudinal designs.

Results: There was an increased risk of any psychotic outcome in individuals who had ever used cannabis (pooled adjusted odds ratio = 1.41, 95% CI 1.20-1.65). Findings were consistent with a dose-response effect, with greater risk in people who used cannabis more frequently (2.09, 95% CI 1.54-2.84). Findings for depression, suicidal thoughts, and anxiety outcomes were less consistent. In both cases (psychotic and affective outcomes), a substantial confounding effect was present.

Conclusions: The findings are consistent with the view that cannabis increases risk of psychotic outcomes independent of transient intoxication effects, though evidence is less strong for affective outcomes. Although cannabis use and the development of psychosis are strongly associated, it is difficult to determine causality and it is possible that the association results from confounding factors or bias. The authors did conclude that there is sufficient evidence to warn young people that using cannabis could increase their risk of developing a psychotic illness later in life.

Date Rape Drugs

- GHB
- Flunitrazepam (Rohypnol®)
- Ketamine

Emerging Medical Uses of Hallucinogens

Many hallucinogens are currently under investigation for therapeutic benefit; LSD & Psilocybin for end of life anxiety, MDMA for PTSD. Ketamine for rapid treatment of depression, ibogaine derivatives for addiction.
Somatic Symptom and Related Disorders

General Characteristics
• physical signs and symptoms lacking objective medical support in the presence of psychological factors that are judged to be important in the initiation, exacerbation, or maintenance of the disturbance
• cause significant distress or impairment in functioning
• symptoms are produced unconsciously and are not the result of malingering or factitious disorder, which are disorders of voluntary presentation of symptoms (or intentionally inducing, e.g. injecting feces) for secondary gain
• primary gain: somatic symptom represents a symbolic resolution of an unconscious psychological conflict; serves to reduce anxiety and conflict with no external incentive
• secondary gain: the sick role; external benefits obtained or unpleasant duties avoided (e.g. work)

Management of Somatic Symptom and Related Disorders
• brief, regular scheduled visits with GP to facilitate therapeutic relationship and help patient feel cared for
• limit number of physicians involved in care, minimize medical investigations; coordinate necessary investigations
• emphasis on what the patient can change and control; the psychosocial coping skills, not their physical symptoms (functional recovery > explanation of symptoms)
• do not tell patient it is “all in their head,” emphasize these disorders are real entities or functional in nature
• psychotherapy: CBT, mindfulness interventions, biofeedback, conflict resolution
• minimize psychotropic drugs: anxioleptics in short-term only, antidepressants for comorbid depression and anxiety

Somatic Symptom Disorder

DSM-5 Diagnostic Criteria for Somatic Symptom Disorder
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
A. one or more somatic symptoms that are distressing or result in significant disruption of daily life
B. excessive thoughts, feelings, or behaviours related to the somatic symptoms or associated health concerns as manifested by at least one of the following
  1. disproportionate and persistent thoughts about the seriousness of one's symptoms
  2. persistently high level of anxiety about health or symptoms
  3. excessive time and energy devoted to these symptoms or health concerns
C. although any one somatic symptom may not be continuously present, the state of being symptomatic is persistent (typically >6 mo)
• somatic symptom disorder with predominant pain (previously pain disorder) for those whose somatic symptom is primarily pain
• patients have physical symptoms and believe these symptoms represent the manifestation of a serious illness
• persistent belief despite negative medical investigations and may develop different symptoms over time
• lifetime prevalence may be around 5-7% in the general adult population
• females tend to report more somatic symptoms than males do, cultural factors may influence sex ratio
• complications: anxiety and depression commonly comorbid (up to 80%), unnecessary medications or surgery
• often a misdiagnosis for an insidious illness so rule out all organic illnesses (e.g. multiple sclerosis)

Illness Anxiety Disorder
• preoccupation with fear of having, or the idea that one has, a serious disease, to the point of causing significant impairment
• convictions persist despite negative investigations and medical reassurance
• somatic symptoms are mild or not present
• there is a high level of anxiety about health and the individual is easily alarmed about personal health status
• person engages in maladaptive behaviour such as excessive physical checking or total healthcare avoidance
• duration is ≥6 mo; onset in 3rd-4th decade of life
• a new diagnostic entity so epidemiology is not well known; however, it is likely less common than SSD
• possible role for SSRIs due to generally high level of anxiety
**Conversion Disorder (Functional Neurological Symptom Disorder)**

- one or more symptoms or deficits affecting voluntary motor or sensory function that mimic a neurological or GMC (e.g. impaired coordination, local paralysis, double vision, seizures, or convulsions)
- does not need to be preceded by a psychological event as per previous DSM criteria, however this is still worth exploring as many patients will present after such an event or related to a medical diagnosis in a first-degree relative
- 2-5/100,000 in general population; 5% of referrals to neurology clinics
- more common in rural populations and in individuals with little medical knowledge
- spontaneous remission in 95% of acute cases, 50% of chronic cases (>6 mo)
- incompatible findings detected from specific neurological testing can help differentiate between functional and neurological origin (e.g. Hoover's sign, dermatome testing)

**Dissociative Disorders**

**Definition**
- severe dissociation resulting in breakdown of integrated functions of consciousness and perception of self
- differential diagnosis: PTSD, acute stress disorder, borderline personality disorder, somatic symptom disorder, substance abuse, GMC (various neurologic disorders including complex/partial seizures, migraine, Cotard syndrome)

**Dissociative Identity Disorder**

disruption of identity characterized by two or more distinct personality states or an experience of possession
- can manifest as sudden alterations in sense of self and agency (ego-dystonic emotions, behaviours, speech)
- features recurrent episodes of amnesia (declarative or procedural)

**Dissociative Amnesia**

- inability to recall important autobiographical information, usually of a traumatic or stressful nature, that is inconsistent with normal forgetting and not attributable to a psychiatric disorder or medical illness
- localized/selective amnesia: failure to recall all/some events during a prescribed period of time
- generalized amnesia: (more rare) complete loss of memory for one’s life history, ± procedural knowledge, ± semantic knowledge. Usually sudden onset. Often presents with perplexity, disorientation, aimless wandering

**Depersonalization/Derealization Disorder**

- persistent or recurrent episodes of one or both of:
  - depersonalization: experiences of detachment from oneself, feelings of unreality, or being an outside observer to one’s thoughts, feelings, speech, and actions (can feature distortions in perception including time, as well as emotional and physical numbing)
  - derealization: experiences of unreality or detachment with respect to the surroundings (e.g. feeling as if in a dream, or that the world is not real, external visual world is foggy or distorted)
- transient (seconds-hours) experiences of this nature are quite common in the general population
- episodes can range from hours-years, patients are often quite distressed and verbalize concern of “going crazy”

**Fugue**

Purposeful travel or bewildered wandering while in amnesic state

**La belle indifférence**

An inappropriately cavalier patient attitude in the face of serious symptoms; classically associated with conversion disorder
Sleep Disorders

for more information regarding normal sleep cycles and the illnesses described, see Neurology, Sleep Disorders, N46

Overview

• adequate sleep is essential to normal functioning; deprivation can lead to cognitive impairment and increased mortality
• circadian rhythms help regulate mood and cognitive performance
• neurotransmitters commonly implicated in psychiatric illnesses also regulate sleep
  ▪ acetylcholine activity and decreased activity of monoamine neurotransmitters is associated with greater REM sleep
  ▪ decreased adrenergic and cholinergic activity are associated with NREM sleep
• depression is associated with decreased Δ (deep, slow-wave) sleep, decreased REM latency, and increased REM density
• criteria
  ▪ must cause significant distress or impairment in normal functioning
  ▪ not due to a GMC or medications/drugs (unless specified)

Management

• pharmacological treatments are illness-specific
  ▪ non-benzodiazepines preferable (e.g. trazodone, zopiclone, quetiapine), but benzodiazepines a short term option
  ▪ medication should not be prescribed without having first made a diagnosis and considering major psychiatric illnesses (major depression and alcohol use disorders are common etiologies)
• sleep hygiene is a simple, effective, but often underutilized method for addressing sleep disturbances; recommendations include
  ▪ waking up and going to bed at same time every day, including on weekends
  ▪ avoiding long periods of wakefulness in bed
  ▪ not using bed for non-sleep activities (reading, TV, work)
  ▪ avoiding napping
  ▪ discontinuing or reducing consumption of alcohol, caffeine, drugs
  ▪ exercising at least 3-4x per week (but not in the evening, if this interferes with sleep)
• Cognitive Behavioural Therapy for insomnia (CBTi)

</tbody>
</table>
Sexuality and Gender

Gender Dysphoria

Definition
- the distress that may coincide with conflict between one's experienced/expressed gender and one's assigned gender

Typical Presentation
- strong and persistent cross-gender identification
- desire to be rid of primary/secondary sex characteristics and to gain the primary/secondary sex characteristics of their identified gender
- repeated stated desire or insistence that one is of the opposite sex
- intense desire to participate in the stereotypical games and pastimes of the opposite sex
- strong preference for playmates of the opposite sex
- significant distress or impairment in functioning and persistent discomfort with his or her sex or gender role

Treatment
- psychotherapy
- hormonal therapy
- sexual reassignment surgery

Paraphilic Disorders

Definition
- intense and persistent sexual interest that is not sexual interest in genital stimulation or preparatory fondling with phenotypically normal, physically mature, consenting human partners
- paraphilic disorder: paraphilia that causes distress or functional impairment to the individual, or a paraphilia whose realization entails personal harm, or risk of harm to others
- subtypes: voyeuristic, exhibitionistic, frotteuristic, sexual masochism, sexual sadism, pedophilic, fetidistic, transvestic, other specified paraphilic disorder, unspecified paraphilic disorder
- rarely self referred; come to medical attention through interpersonal or legal conflict
- person usually has more than one paraphilia; 5% of paraphilias attributed to women
- typical presentation: begins in childhood or early adolescence; increasing in complexity and stability with age
- chronic, decreases with advancing age but may increase with stress

Treatment
- anti-androgen drugs
- behaviour modification
- psychotherapy

SEXUAL DYSFUNCTION
- see Gynecology, GY33 and Urology, U34

Eating Disorders

Definition
- eating disorders are characterized by a persistent disturbance of eating that impairs psychosocial functioning or health
- disorders include: anorexia nervosa, avoidant/restrictive food intake disorder, binge eating disorder, bulimia nervosa, pica and rumination disorder.

Epidemiology
- anorexia nervosa (AN): 1% of adolescent and young adult females; onset 13-20 yr old
- bulimia nervosa (BN): 2-4% of adolescent and young adult females; onset 16-18 yr old
- F:M=10:1; mortality 5-10%

Etiology
- multifactorial: psychological, sociological, and biological associations
- individual: perfectionism, lack of control in other life areas, history of sexual abuse
- personality: obsessive-compulsive, histrionic, borderline
- familial: maintenance of weight equilibrium and control in dysfunctional family
• cultural factors: prevalent in industrialized societies, idealization of thinness in the media
• genetic factors
  • AN: 6% prevalence in siblings, with one study of twin pairs finding concordance in 9 of 12 monozygotic pairs versus concordance in 1 of 14 dizygotic pairs
  • BN: higher familial incidence of affective disorders than the general population

Risk Factors
• physical factors: obesity, chronic medical illness (e.g. DM)
• psychological factors: individuals who by career choice are expected to be thin, family history (mood disorders, eating disorders, substance abuse), history of sexual abuse (especially for BN), homosexual males, competitive athletes, concurrent associated mental illness (depression, OCD, anxiety disorder [especially panic and agoraphobia], substance abuse [specifically for BN])

Anorexia Nervosa

DSM-5 Diagnostic Criteria for Anorexia Nervosa
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. intake and weight: restriction of energy intake relative to requirements, leading to a significantly low body weight in the context of age, sex, developmental trajectory, and physical health. Significantly low weight is defined as a weight that is less than minimally normal or, for children and adolescents, less than that minimally expected
B. fear or behaviour: intense fear of gaining weight or of becoming fat, or persistent behaviour that interferes with weight gain, even though at a significantly low weight
C. perception: disturbance in the way in which one's body weight or shape is experienced, undue influence of body weight or shape on self-evaluation or persistent lack of recognition of the seriousness of the current low body weight
• specifiers: partial remission, full remission, severity based on BMI (mild = BMI >17 kg/m², moderate = BMI 16-16.99 kg/m², severe = BMI 15-15.99 kg/m², extreme = BMI <15 kg/m²), type (restricting = during last 3 mo no episodes of binge-eating or purging vs. binge-eating/purging type = in last 3 mo have participated in recurrent episodes of binge-eating/purging)

Management
• psychotherapy: individual, group, family (gold standard): address food and body perception, coping mechanisms health effects
• medications of little value
• outpatient and inpatient programs are available
• inpatient hospitalization for treatment of eating disorders is rarely on an acute basis (unless there is a concurrent psychiatric reason for emergent admission e.g. suicide risk)
• criteria to admit to medical ward for hospitalization: <65% of standard body weight (<85% of standard body weight for adolescents), hypovolemia requiring intravenous fluid, heart rate <40 bpm, abnormal serum chemistry, or if actively suicidal
• agree on target body weight on admission and reassure this weight will not be surpassed
• monitor for complications of AN (see Table 9, PS33)
• monitor for refeeding syndrome
  • potentially life-threatening metabolic response to refeeding in severely malnourished patients resulting in severe shifts in fluid and electrolyte levels
  • complications include hypophosphatemia, congestive heart failure, cardiac arrhythmias, delirium, and death
  • prevention: slow refeeding, gradual increase in nutrition, supplemental phosphorus, and close monitoring of electrolytes and cardiac status

Prognosis
• early intervention much more effective (adolescent onset has much better prognosis than adult onset)
• 1 in 10 adolescents continue to have anorexia nervosa as adults
• with treatment, 70% resume a weight of at least 85% of expected levels and about 50% resume normal menstrual function
• eating peculiarities and associated psychiatric symptoms are common and persistent
• long-term mortality: 10-20% of patients hospitalized will die in next 10-30 yr (secondary to severe and chronic starvation, metabolic or cardiac catastrophes, with a significant proportion committing suicide)

Bulimia Nervosa

DSM-5 Diagnostic Criteria for Bulimia Nervosa
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. recurrent episodes of binge-eating: an episode of binge-eating is characterized by both of the following
• eating, in a discrete period of time, an amount of food that is definitely larger than what most individuals would eat during a similar period of time and under similar circumstances
• a sense of lack of control over eating during the episode
B. recurrent inappropriate compensatory behaviour in order to prevent weight gain, such as self-induced vomiting, misuse of laxatives, diuretics, enemas, or other medications, fasting, or excessive exercise
C. the binge-eating and inappropriate compensatory behaviours both occur, on average, at least once a week for 3 mo
D. self-evaluation is unduly influenced by body shape and weight
E. the disturbance does not occur exclusively during episodes of AN
   • specifiers: partial remission, full remission, severity (measured in # of inappropriate compensatory behaviours/wk: mild = 1-3, moderate = 4-7, severe = 8-13, extreme = 14+)

Associated Features
• fatigue and muscle weakness due to repetitive vomiting and fluid/electrolyte imbalance
• tooth decay
• swollen appearance around angle of jaw and puffiness of eye sockets due to fluid retention
• reddened knuckles, Russell’s sign (knuckle callus from self-induced vomiting)
• trouble concentrating
• weight fluctuation over time

Management
• admission for significant electrolyte abnormalities
• biological: treatment of starvation effects, SSRIs (fluoxetine most evidence) as adjunct
• psychological: develop trusting relationship with therapist to explore personal etiology and triggers, CBT, family therapy, recognition of health risks
• social: challenge destructive societal views of women, use of hospital environment to provide external patterning for normative eating behaviour

Prognosis
• relapsing/remitting disease
• good prognostic factors: onset before age 15, achieving a healthy weight within 2 yr of treatment
• poor prognostic factors: later age of onset, previous hospitalizations, individual and familial disturbance
• 60% good treatment outcome, 30% intermediate outcome, 10% poor outcome

Binge-Eating Disorder

Definition
• recurrent episodes of binge-eating (as defined by criteria A of BN) that are associated with eating much more rapidly than normal, eating until feeling uncomfortably full, eating large amounts when not physically hungry, eating alone because embarrassed by how much one is eating, feeling disgusted with self/depressed, very guilty afterwards at least once/wk x 3 mo
• not associated with any compensatory behaviours
• dieting usually follows binge-eating (vs. BN where dysfunctional dieting typically precedes binge-eating)
• associated with health consequences (e.g. increased risk of weight gain, obesity)

Epidemiology
• F:M = 2:1
• begins in adolescence or young-adulthood

Treatment
• CBT

Avoidant/Restrictive Food Intake Disorder

Definition
• eating/feeding disturbance to the extent of persistent failure to meet appropriate nutritional and/or energy needs, resulting in significant weight loss/growth failure and nutritional deficiencies. Patients experience disturbances in psychosocial functioning and may become dependent on enteral feeding/oral nutritional supplementation
• does not occur during an episode of AN or BN
• no evidence of distress in the way in which one’s body weight or shape is experienced

Risk Factors
• temperament (e.g. anxiety disorders), environment (e.g. familial anxiety), genetic (e.g. history of GI conditions)
• begins in infancy and can persist into adulthood

Treatment
• psychoeducation
• behaviour modification
• psychotherapy

Personality Disorders

- in the literature, personality and its disorders are better understood using a trait-based dimensional approach (e.g. 5 major traits such as extraversion, agreeableness, conscientiousness, neuroticism, and openness to experiences rated on a continuum of dysfunctional effects) rather than discrete categories; however, the discrete categories still remain in the current DSM and will be referenced here.

General Information

- an enduring pattern of inner experience and behaviour that deviates markedly from the expectations of the individual’s culture; manifested in two or more of: cognition, affect, interpersonal functioning, impulse control
- inflexible and pervasive across a range of situations
- pattern is stable and well established by adolescence or early adulthood (vs. a sudden onset)
- associated with many complications, such as depression, suicide, violence, brief psychotic episodes, multiple drug use, and treatment resistance
- relationship building and establishing boundaries are important; focus should be placed on validating, finding things to be truly empathetic about, and speaking to the patient’s strengths.
- mainstay of treatment is psychotherapy, add pharmacotherapy to treat associated psychiatric disorders (i.e. depression, anxiety, substance abuse)

Classification

- personality disorders are divided into three clusters (A, B and C), with shared features among disorders within each
# Table 10. Description and Diagnosis of Personality Disorders

## Cluster A: "Mad" Personality Disorders

<table>
<thead>
<tr>
<th>Disorder</th>
<th>Description</th>
<th>Diagnosis Requires</th>

<td>Threats interpreted in benign remarks</td>
<td></td>
</tr>
</tbody>
</table>

| Schizotypal Personality Disorder (3-5.6%) | Pattern of eccentric behaviours; peculiar thought patterns | 5+ of: ME PECULIAR |
| | Diagnosis requires | |
| | 1. Magical thinking | |
| | 2. Experiences unusual perceptions (including body illusions) | |
| | 3. Paranoid ideation | |
| | 4. Eccentric behaviour or appearance | |
| | 5. Constricted or inappropriate affect | |
| | 6. Unusual thinking/speech (e.g. vague, stereotyped) | |
| | 7. Lacks close friends | |
| | 8. Ideas of reference | |
| | 9. Anxiety in social situations | |
| | (Note: Rule out psychotic/pervasive developmental disorders - this is not part of the criteria) | |

## Cluster B: "Bad" Personality Disorders

<table>
<thead>
<tr>
<th>Disorder</th>
<th>Description</th>
<th>Diagnosis Requires</th>
</tr>
</thead>
<tbody>
<tr>
<td>Borderline Personality Disorder (2-4%)</td>
<td>Unstable moods and behaviour, feel alone in the world, problems with self-image. History of repeated suicide attempts, self-harm behaviours. Inpatients commonly report history of sexual abuse. Tends to fizzle out as patients age. DBT is the principal treatment (see Psychotherapy, PS40)</td>
<td>5+ of: IMPULSIVE</td>
</tr>
<tr>
<td></td>
<td><strong>10% suicide rate</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Diagnosis requires</td>
<td></td>
</tr>
<tr>
<td></td>
<td>1. Impulsive (min. 2 self-damaging ways, e.g. sex/drugs/spending)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>2. Mood/affect instability</td>
<td></td>
</tr>
<tr>
<td></td>
<td>3. Paranoid or dissociation under stress</td>
<td></td>
</tr>
<tr>
<td></td>
<td>4. Unstable self-image</td>
<td></td>
</tr>
<tr>
<td></td>
<td>5. Labile intense relationships</td>
<td></td>
</tr>
<tr>
<td></td>
<td>6. Suicidal gestures / self-harm</td>
<td></td>
</tr>
<tr>
<td></td>
<td>7. Inappropriate anger</td>
<td></td>
</tr>
<tr>
<td></td>
<td>8. Avoiding abandonment (real or imagined, frantic efforts to)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>9. Emptiness (feelings of)</td>
<td></td>
</tr>
</tbody>
</table>

| Narcissistic Personality Disorder (2%) | Sense of superiority, needs constant admiration, lacks empathy, but with fragile sense of self. Consider themselves "special" and will exploit others for personal gain. | 5+ of: GRANDIOSE |
| | Diagnosis requires | |
| | 1. Grandiose | |
| | 2. Requires excessive admiration | |
| | 3. Arrogant | |
| | 4. Needs to be special (and associate with other specials) | |
| | 5. Dreams of success, power, beauty, love | |
| | 6. Interpersonally exploitative | |
| | 7. Others (lacks empathy, unable to recognize feelings/needs of) | |
| | 8. Sense of entitlement | |
| | 9. Envious (or believes others are envious) | |

| Antisocial Personality Disorder (M: 3%, F: 1%) | Lack of remorse for actions, manipulative and deceitful, often violate the law. May appear charming on first impression. Pattern of disregard for others and violation of others’ rights must be present before age 15; however, for the diagnosis of ASPD patients must be at least 18. Strong association with Conduct Disorder, history of trauma/abuse common. (see Child Psychiatry) | 3+ of: CORRUPT |
| | Diagnosis requires | |
| | 1. Cannot conform to law | |
| | 2. Obligations ignored (irresponsible) | |
| | 3. Reckless disregard for safety | |
| | 4. Remorseless | |
| | 5. Underhanded (deceitful) | |
| | 6. Planning insufficient (impulsive) | |
| | 7. Temper (irritable and aggressive) | |

| Histrionic Personality Disorder (1.3-3%) | Attention-seeking behaviour and excessively emotional. Are dramatic, flamboyant, and extroverted. Cannot form meaningful relationships. Often sexually inappropriate | 5+ of: ACTRESSS |
| | Diagnosis requires | |
| | 1. Appearance used to attract attention | |
| | 2. Centre of attention (else uncomfortable) | |
| | 3. Theatrical | |
| | 4. Relationships (believed to be more intimate than they are) | |
| | 5. Easily influenced | |
| | 6. Seductive behaviour | |
| | 7. Shallow expression of emotions (which rapidly shift) | |
| | 8. Speech (impressionistic and vague) | |
Table 10. Description and Diagnosis of Personality Disorders (continued)

<table>
<thead>
<tr>
<th>Cluster C “Sad” Personality Disorders</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Patients seem anxious, fearful</td>
</tr>
<tr>
<td>• Familial association with anxiety disorder</td>
</tr>
<tr>
<td>• Common defense mechanisms: isolation, avoidance, hypochondriasis</td>
</tr>
</tbody>
</table>

**Avoidant Personality Disorder (0.5-1.5%)**
Timid and socially awkward with a pervasive sense of inadequacy and fear of criticism. Fear of embarrassing or humiliating themselves in social situations so remain withdrawn and socially inhibited. Diagnosis requires 4+ of: CRINGES
1. Criticism or rejection preoccupies thoughts in social situations
2. Restraint in relationships due to fear of being shamed
3. Inhibited in new relationships due to fear of inadequacy
4. Needs to be sure of being liked before engaging socially
5. Gets around occupational activities requiring interpersonal contact
6. Embarrassment prevents new activity or taking risks
7. Self-viewed as unappealing or inferior

**Dependent Personality Disorder (1.6-6.7%)**
Pervasive and excessive need to be taken care of, excessive fear of separation, clinging and submissive behaviours. Difficulty making everyday decisions. Useful to set regulated treatment schedule (regular, brief visits) and being firm about in between issues. Encourage patient to do more for themselves, engage in own problem-solving. Diagnosis requires 5 of: RELIANCE
1. Reassurance required for everyday decisions
2. Expressing disagreement difficult
3. Life responsibilities assumed by others
4. Initiating projects difficult (because no confidence)
5. Alone (feels helpless and uncomfortable when alone)
6. Nurture (goes to excessive lengths to obtain)
7. Companionship sought urgently
8. Exaggerated fears of being left to care for self

**Obsessive-Compulsive Personality Disorder (3-10%)**
Preoccupation with orderliness, perfectionism, and mental and interpersonal control. Is inflexible, closed-off, and inefficient. Diagnosis requires 4+ of: SCRIMPER
1. Stubborn
2. Cannot discard worthless objects
3. Rule/detail obsessed (to point of activity lost)
4. Inflexible in matters of morality, ethics, values
5. Misery
6. Perfectionistic
7. Excludes leisure due to devotion to work
8. Reluctant to delegate to others

<td>No psychosis, may have ideas of reference, paranoid ideation, odd beliefs and magical thinking</td>
</tr>
<tr>
<td>Relationships</td>
<td>Solitary, NO desire for social relationships</td>
<td>Lacks close relationships, INTERESTED in relationships but socially inept</td>
</tr>
</tbody>
</table>

**Child Psychiatry**

**Developmental Concepts**

- **temperament**: a child’s innate psycho-physiological and behavioural characteristics (e.g. emotionality, activity, and sociability); spectrum from “difficult” to “slow-to-warm-up” to “easy temperament”
- **parental fit**: the congruence between parenting style (authoritative, permissive) and child temperament
- **attachment**: special relationship between child and primary caretaker(s); develops during first year, the caretaker’s attachment style is the best predictor of their child’s attachment style, refer to Table 12
- **separation anxiety** (normal between 10-18 mo): where separation from attachment figure results in distress

Table 12. Attachment Models

<table>
<thead>
<tr>
<th>Parent/Caregiver</th>
<th>Attachment Type</th>
<th>Features in Child</th>
</tr>
</thead>
<tbody>
<tr>
<td>Loving, consistently available, sensitive, and responsive</td>
<td>Secure</td>
<td>Freely explores and engages strangers well (as long as mother in close proximity), upset with caregiver’s departure, happy with return</td>
</tr>
<tr>
<td>Rejecting, unavailable psychologically, insensitive responses</td>
<td>Insecure (avoidant)</td>
<td>Ignores caregiver, shows little emotion with arrival or departure, little exploration</td>
</tr>
<tr>
<td>Inconsistent, insensitive responses, role reversal</td>
<td>Insecure (ambivalent/resistant)</td>
<td>Clingy but inconsolable, often displays anger or helplessness, little exploration</td>
</tr>
<tr>
<td>Frightening, dissociated, sexualized, or atypical</td>
<td>Disorganized</td>
<td>Simultaneous approach/avoidance and stress related straining behaviour</td>
</tr>
<tr>
<td>Often history of trauma or loss</td>
<td></td>
<td></td>

</table>

**Tips for the Child Interview**

- Use language the child will understand (i.e. don’t ask about feeling of worthlessness, ask about whether they feel like they’re a bad kid)
- Children in some cultures are taught to be quiet and avoid eye contact with adults who are authority figures (do not mistake with depression)
- Use developmentally-appropriate questions (i.e. don’t ask about lack of interest in activities, ask children whether they feel bored)
Mood Disorders

MAJOR DEPRESSIVE DISORDER

Epidemiology
pre-pubertal 1-2% (no gender differences); post-pubertal 4-18% (F:M = 2:1)

Clinical Presentation
• see Mood Disorders, PS9
• only difference in diagnostic criteria is that irritable mood may replace depressed mood
• physical factors: insomnia (children), hypersomnia (adolescents), somatic complaints, substance abuse, decreased hygiene
• psychological factors: irritability, boredom, anhedonia, low self-esteem, deterioration in academic performance, social withdrawal, lack of motivation, listlessness
• comorbid diagnoses: anxiety, ADHD, ODD, conduct disorder, and eating disorders

Treatment
• majority never seek treatment
• individual (CBT, IPT), family therapy and education, modified school program
• SSRIs: strongest evidence for fluoxetine. Escitalopram and sertraline would be second line medications of choice
• close follow-up for adolescents starting SSRIs to monitor for increased suicidal ideation or behavior
• ECT: only in adolescents who have severe illness, psychotic features, catatonic features, persistently suicidal
• internet based psychotherapy, light therapy, self-help books

Prognosis
• prolonged episodes, up to 1-2 yr
• adolescent onset predicts chronic mood disorder; up to 2/3 will have another depressive episode within 5 yr
• complications: negative impact on family and peer relationships, school failure significantly increased risk of suicide attempt (10%) or completion (however, suicide risk low for pre-pubertal children), substance abuse

DISRUPTIVE MOOD DYSREGULATION DISORDER

Clinical Presentation
• severe, developmentally inappropriate, recurrent verbal or behavioral temper outbursts at least 3x per wk
• mood is predominantly irritable or angry in between outbursts, as observable by others
• these symptoms occur before 10 yr, have been occurring for 12 mo, with no more than 3 consecutive mo free from symptoms
• high rates of comorbidities; ADHD, ODD, anxiety disorders, depressive disorders

BIPOLAR DISORDER

Clinical Presentation
• see Bipolar Disorder, PS12
• mixed presentation and psychotic symptoms (hallucinations and delusions) more common in adolescent population than adult population
• unipolar depression may be an early sign of adult bipolar disorder
• ~30% of psychotic depressed adolescents receive a bipolar diagnosis within 2 yr of presentation
• associated with rapid onset of depression, psychomotor retardation, mood-congruent psychosis, affective illness in family pharmaco logically-induced mania

Treatment
• pharmacotherapy: mood stabilizers and/or antipsychotics
• psychotherapy: CBT, Family Focused Therapy

Anxiety Disorders

• lifetime prevalence 10-20%; F:M = 2:1

Clinical Presentation
• children and adolescents rarely vocalize their anxiety but instead exhibit behavioral manifestations
• school problems, recurrent physical symptoms (abdominal pain, headaches) especially in mornings, social and relationship problems, social withdrawal and isolation, family conflict, difficulty with sleep initiation, temper tantrums, irritability and mood symptoms, alcohol and drug use in adolescent

Differential Diagnosis
• depressive disorders, ODD, truancy
• clinical judgment important to differentiate developmentally normal from pathological anxiety
• for school avoidance, differentiate fear of general performance and humiliation. Consider anxiety about separation, and rule out bullying and school refusal due to learning disorder
Course and Prognosis
- better prognosis with later age of onset, lower co-morbidities, early initiation of treatment, ability to maintain school attendance and peer relationships, absence of social anxiety disorder
- with treatment, up to 80% of children will not meet criteria for their anxiety disorder at 3 yr follow-up, but up to 30% will meet criteria for another psychiatric disorder

Treatment
- similar principles for most childhood anxiety disorders due to overlapping symptomatology and frequent comorbidity
- family psychotherapy, predictive and supportive environment
- CBT: child and parental education, relaxation techniques (e.g. deep breathing), exposure/desensitization, recognizing and correcting anxious thoughts
- pharmacotherapy: SSRIs (e.g. fluoxetine), benzodiazepines (alprazolam, clonazepam) have evidence – use with caution due to addictive and abuse potential as well as disinhibiting effect, especially in neurodevelopmental delay, fluvoxamine and sertraline also have good evidence, particularly for OCD

SEPARATION ANXIETY DISORDER
- excessive and developmentally inappropriate anxiety on real, threatened, or imagined separation from primary caregiver or home, with physical or emotional distress for at least 4 wk (e.g. worries of something happening to parent or themselves if separated)
- school refusal (75%) and comorbid major depression common (2/3)
- persistent worry, refusal to sleep alone, clinging, nightmares involving separation, somatic symptoms

SOCIAL ANXIETY DISORDER (SOCIAL PHOBIA)
- anxiety, fear, and/or avoidance provoked by situations where child feels under the scrutiny of others
- must distinguish shy child, child with issues functioning socially (e.g. autism), and child with social anxiety
- diagnosis only if anxiety interferes significantly with daily routine, social life, academic functioning, or if markedly distressed. Must occur in settings with peers, not just adults
- features: temper tantrums, freezing, clinging behaviour, mutism, excessively timid, stays on periphery, refuses to be involved in group play
- significant implication for future quality of life if untreated; lower levels of satisfaction in leisure activities, higher rates of school dropout, poor workplace performance, increased rates of remaining single

SELECTIVE MUTISM
- consistent failure to speak in specific social situations where speaking is expected, despite speaking in other situations
- the disturbance interferes with educational or occupational achievement or with social communication

GENERALIZED ANXIETY DISORDER
- diagnostic criteria same as adults (see Generalized Anxiety Disorder, PS15)
  note: only 1 item is required in children for Criteria C
- often redo tasks, show dissatisfaction with their work, and tend to be perfectionistic
- often fearful in multiple settings and expect more negative outcomes when faced with academic or social challenges, and require reassurance and support to take on new tasks

SPECIFIC PHOBIA
- common phobias in childhood: fear of heights, small animals, doctors, dentists, darkness, loud noises, thunder, and lightning

Neurodevelopmental Disorders

Autism Spectrum Disorder

Diagnosis
- persistent deficits in social communication and interaction, manifested in three areas:
  - social-emotional reciprocity: ranging, for example, from abnormal social approach and failure of normal back-and-forth conversation, to reduced sharing of interests, emotions, or affect, to failure to initiate or respond to social interactions
  - nonverbal communicative behaviours, ranging, for example, from poorly integrated verbal and nonverbal communication, to abnormalities in eye contact and body language or deficits in understanding and use of gestures, to a total lack of facial expressions and nonverbal communication
  - developing, maintaining, and understanding relationships, ranging, for example, from difficulties adjusting behaviour to suit various social contexts, to difficulties in sharing imaginative play or in making friends, to absence of interest in peers
- restricted, repetitive patterns of behaviour, interests, or activities Manifested by two or more of the following:
  - stereotyped or repetitive motor movements, insistence on sameness, highly restricted fixed interests, hyper-/hypo-reactivity to sensory input
  - symptoms must be present in early developmental period

Attachment type can be assessed in infants 10-18 mo of age using the Strange Situation test, in which the child is stressed by the caregiver being removed from the situation and the stranger staying. Attachment style is measured by the child’s behaviour during the reunion with the caregiver

Attachment problems may present as a child who is difficult to soothe, has difficulty sleeping, problems feeding, tantrums, or behavioural problems

The shy child is quiet and reluctant to participate but slowly ‘warms up’

Fluoxetine, Cognitive-Behavioural Therapy and Their Combination for Adolescents with Depression: Treatment for Adolescents with Depression Study (TADS) Randomized C controlled Trial

Purpose: To evaluate effectiveness of fluoxetine alone, cognitive behavioural therapy (CBT) alone, CBT with fluoxetine and placebo among adolescents with major depressive disorder (MDD)

Methods: Randomized controlled trial at 13 US academic and community clinics between spring 2000-summer 2003, including patients aged 12-17 with a primary DSM-IV diagnosis of MDD assigned to one of the aforementioned four treatment arms.

The primary outcome was the Children’s Depression Rating Scale-Revised (CDRS-R) total score.

Results: Fluoxetine with CBT had a statistically significant CDRS-R score as compared to placebo (p=0.001) with a 71% response rate. This combination was greater than fluoxetine alone (p=0.03), and CBT alone (p=0.01). Fluoxetine alone was greater than CBT alone (p=0.01).

Conclusion: Combination of fluoxetine with CBT offered the most favourable benefit-risk tradeoff for adolescents with MDD

Newer Generation Antidepressants for Depressive Disorders in Children and Adolescents

Cochrane Database Syst Rev 2012;11:CD004851

Purpose: To determine the efficacy and adverse outcomes of newer generation antidepressants versus placebo for child and adolescent depressive disorders

Methods: Meta-analysis of RCTs, crossover trials and cluster trials with children and adolescents aged 6 to 18 years and a diagnosis of depressive disorder, assigned to antidepressants or placebo.

Depression severity score was the main outcome measure.

Results: Nineteen trials involving 3,335 participants were included. Children treated with an antidepressant had lower depression severity score and higher rates of response/ remission. Children on antidepressants were also found to be at increased risk (58%) of suicide-related outcome (RR 1.58; 95% CI 1.02-2.45).

Conclusion: In children and adolescents, antidepressants are effective at treating depression, yet may cause a higher chance of suicide-related outcomes.
Neurodevelopmental Disorders

- symptoms cause clinically significant impairment in social, occupational, or other important areas of current functioning
- not better explained by intellectual disability or global developmental delay
- specifiers
  - current severity: requiring very substantial support, requiring substantial support, requiring support
  - ± language impairment, ± intellectual impairment
  - associated with known medical or genetic condition or environmental factors (i.e. Rett's disorder)

Differential Diagnosis
- developmental disability, childhood schizophrenia, social phobia, OCD, communication disorder, non-verbal learning disorder, ADHD, abuse, hearing or visual impairment, seizure disorder, motor impairment

Management
- hearing and vision test to rule out impairment
- psychological testing to assess intellectual functioning and learning
- chromosomal analysis to rule out abnormalities (e.g. Trisomy 21, Fragile X syndrome)
- rule out psychotic disorders, social problems, depression, anxiety abuse

Treatment
- team-based: school, psychologist, occupational therapist, physiotherapist, speech and language therapy, pediatrics, psychiatry
- psychosocial: family education and support, school programming, behaviour management, social skills training
- treat concomitant disorders such as ADHD, tics, OCD, anxiety, depression, and seizure disorder
- pharmacotherapy: atypical antipsychotics (for irritability, aggression, agitation, self-mutilation, tics), SSRIs (for anxiety, depression), stimulants (for associated inattention and hyperactivity)

Prognosis
- variable, but improves with early intervention
- better if IQ >60 and able to communicate

Attention Deficit Hyperactivity Disorder

- prevalence: 5-12% of school-aged children; M:F = 4:1, although girls may be under-diagnosed
- girls tend to have inattentive/distractible symptoms; boys have impulsive/hyperactive symptoms

Etiology
- genetic: 75% heritability, dopamine candidate genes DAT1, DRD4
- neurobiology: decreased catecholamine transmission, low prefrontal cortex (PFC) activity, increased beta activity on EEG
- cognitive: developmental disability, poor inhibitory control, and other errors of executive function

Diagnosis
- differential: learning disorders, hearing/visual defects, thyroid, atopic conditions, congenital problems (fetal alcohol syndrome, Fragile X), lead poisoning, history of head injury, traumatic life events (abuse)
- diagnosis requires: onset before age 12, persistent symptoms >6 mo, symptoms present in at least two settings (i.e. home, school, work), interferes with academic, family, and social functioning, and is divided into 3 subtypes
  - combined type: ≥6 symptoms of inattention and ≥6 symptoms of hyperactivity-impulsivity
  - predominantly inattentive type: ≥6 symptoms of inattention
  - predominantly hyperactive-impulsive type: ≥6 symptoms of hyperactivity-impulsivity
- for older adolescents (>17 yr) or adults, 5 symptoms required
- does not occur exclusively during the course of another psychiatric disorder

Observe child for “ATTENTION” features
- Annoy[ing]
- Tempor[atural]
- Energetic
- Noisy
- Task incomplet[ion]
- Inattentive
- Oppos[itional]
- Negativ[ism]

Treatment with stimulant medications of ADHD in childhood does not increase the likelihood of substance abuse later in life, contrary to the concerns of many parents and health care providers
**Features**
- difficult to differentiate from highly variable normative behaviour before age 4, but often identified upon school entry
- rule out developmental delay, sensory impairments, genetic syndromes, encephalopathies, or toxins (alcohol lead)
- increased risk of substance abuse, depression, anxiety, academic failure, poor social skills, comorbid CD and/or ODD, adult ASPD
- associated with family history of ADHD, difficult temperamental characteristics

**Treatment**
- non-pharmacological: parent management, anger control strategies, positive reinforcement, social skills training, individual/family therapy, behaviour therapy, tutors, classroom intervention, exercise routines, extracurricular activities, omega-3 fatty acids
- pharmacological: first line: stimulants (methylphenidate, amphetamine salts); second line: atomoxetine; third line/adjunct: nonstimulants (α-agonists; clonidine, guanfacine, NDRI; buproprion)
- for comorbid symptoms: antidepressants, antipsychotics

**Prognosis**
- 70-80% continue into adolescence, but hyperactive symptoms usually abate
- 65% continue into adulthood; secondary personality disorders and compensatory anxiety disorders are identifiable

---

**Disruptive, Impulse Control, and Conduct Disorder**

**Oppositional Defiant Disorder**
- prevalence: 2-16%, M:F after puberty

**Diagnosis**
- pattern of negativistic/hostile and defiant behaviour for ≥6 mo with ≥4 of:
  - angry/irritable mood: easily loses temper, touchy or easily annoyed, often angry and resentful
  - argumentative/defiant: argues with adults/authority figure, defies requests/rules, deliberately annoys, blames others for their own mistakes or misbehaviour
  - vindictive: spiteful or vindictive twice in past 6 mo
  - behaviour causes significant impairment in social, academic, or occupational functioning
  - behaviours do not occur exclusively during the course of a psychotic or mood disorder
  - criteria not met for conduct disorder (CD); if ≥18 yr, criteria not met for ASPD
  - may progress to CD, differentiated by an absence of destructive or physically aggressive behaviour
  - features that typically differentiate ODD from transient developmental stage: onset <8 yr, chronic duration (>6 mo), frequent intrusive behaviour
  - impact of ODD: poor school performance, few friends, strained parent/child relationships, risk of later mood disorders

**Treatment**
- parent: management training, psychoeducation and family therapy to reduce punitive parenting and parent-child conflict
- behavioural therapy: to teach, practice, and reinforce prosocial behaviour
- social: school/day-care interventions
- pharmacotherapy for comorbid disorders

---

**Conduct Disorder**
- prevalence: 1.5-3.4% (M:F = 4:12:1)

**Etiology**
- parental/familial factors: parental psychopathology (e.g. ASPD, substance abuse), child-rearing practices (e.g. child abuse, discipline), low socioeconomic status (SES), family violence
- child factors: difficult temperament, ODD, learning problems, neurobiology
Diagnosis
• differential: ADHD, depression, head injury, substance abuse
• diagnosis: use multiple sources (Achenbach Child Behavioural Checklist, Teacher’s Report Form)
  • pattern of behaviour that violates rights of others and age appropriate social norms with ≥3 criteria noted in past 12 mo and ≥1 in past 6 mo
  • aggression to people and animals: bullying, initiating physical fights, use of weapons, forced sex cruel to people and/or animals, stealing while confronting a person (e.g. armed robbery)
  • destruction of property: arson, deliberately destroying others’ property
  • deceitfulness or theft: breaking and entering, conning others, stealing nontrivial items without confrontation
  • violation of rules: out all night before age 13, often truant from school before age 13, runaway ≥2 times at least overnight or for long periods of time
  • disturbance causes clinically significant impairment in social, academic, or occupational functioning
  • if ≥18 yr, criteria not met for ASPD

• diagnostic types
  • childhood onset: at least one criterion prior to age 10
  • poor prognosis: associated with ODD, aggressiveness, impulsiveness
  • adolescent onset: absence of any criteria until age 10
  • better prognosis; least aggressive, gang-related delinquency
  • mild, moderate, severe

Treatment
• early intervention necessary and more effective; long-term follow-up required
• psychosocial: parent management training, anger replacement training, CBT, family therapy, education/employment programs, social skills training
• pharmacotherapy: for comorbid disorders

Prognosis
• poor prognostic indicators include early-age onset, high frequency, variety of behaviours, pervasiveness (i.e. in home, school, community), comorbid ADHD, early sexual activity, substance abuse
• 50% of CD children become adult ASPD

Intermittent Explosive Disorder

Diagnosis
• recurrent behavioural outbursts representing a failure to control aggressive impulses in children >6 yr, manifested as either
  • verbal or physical aggression that does not damage others or property, occurring 2+ times per wk for 3 mo
  • 3 outbursts involving physical damage to another person, animal or piece of property in the last 12 mo
  • outbursts are out of proportion to triggers or provocation, are not premeditated, and not for primary gain
  • outbursts cause clinically significant impairment in social, academic, or occupational functioning

See Pediatrics
• Child Abuse, P14
• Chronic Abdominal Pain, P39
• Developmental Delay, P22
• Intellectual Disability, P22
• Learning Disabilities, P24
• Sleep Disturbances, P12

See Neurology
• Tic Disorders, N33
• Tourette’s Syndrome, N34

Psychotherapy
• treatment in which a person with mental or physical difficulties aims to achieve symptomatic relief through talks with another person
• psychotherapy is delivered by a specially trained social worker, nurse, psychologist, psychiatrist, counsellor or general practitioner
• various types of therapy exist because of diverse theories of human psychology and mental illness etiology

Common Factors of Psychotherapy
• good evidence that effective psychotherapy creates observable changes in brain circuitry and connectivity, similar to those observed with successful pharmacologic and other treatment modalities
• studies suggest that up to 30-70% of therapy outcome is due to common factors with only 10-40% from specific factors
• common factors are: warmth (unconditional positive regard), accurate empathy, genuineness, goodness of fit
## Table 14. Summary of Psychotherapeutic Modalities

<table>
<thead>
<tr>
<th>Type</th>
<th>Indications</th>
<th>Approach, Technique and Theory</th>
<th>Ideal Candidates</th>
<th>Duration</th>
</tr>
</thead>
</table>
| **Psychoanalytic/Psychodynamic**      | Psychoneuroses; anxiety, obsessional thinking, compulsive or conversion disorders, sexual dysfunction, depressive states | Theory: Exploration of meaning of early experiences and how they affect emotions and patterns of behaviour  
(Recollection (remembering), repetition (reliving with the analyst), working through (gaining insight))  
Techniques: free association, dream interpretation, transference analysis | Psychologically minded, highly motivated, wish to understand selves and not just relieve symptoms  
Able to withstand difficult emotions without fleeing or self-destructive acts  
High level of function | Time intensive:  
Classically: 4-5 times/wk for 3-7 yr  
Psychodynamically oriented therapy: 2-3 times/wk for fewer years |
| **Supportive**                        | Adjustment disorders, psychosomatic disorders, severe psychotic or personality disorders | Ameliorate symptoms through behavioural or environmental restructuring to aid adaptation and facilitate coping  
Help patients feel safe, secure, and encouraged | Individuals in crisis or with severe symptoms in acute or chronic settings  
Low insight, low motivation, “weak” ego systems | Variable (single session to years, though often short intermittent) |
| **Interpersonal**                     | Mood disorders                                                               | Focuses on how interpersonal relationships impact symptoms  
4 key problem areas addressed: grief and loss, role transitions, conflict, interpersonal deficits  
Break the interpersonal cycle: depression, self-esteem, social withdrawal | Individuals with depression or bipolar disorder with some insight and difficult social functioning  
Absence of severe psychotic process, personality disorder, or comorbid substance abuse | 12-20 wk |
| **Behavioural**                       | Most mental health disorders benefit from specific application of behavioural therapy (e.g., behavioural activation for depression; exposure therapy for phobias; contingency management for anorexia nervosa and substance use disorder) | Systematic Desensitization: mastering anxiety-provoking situations by approaching them gradually and in a relaxed state that limits anxiety  
Flooding: confronting feared stimulus for prolonged periods until it is no longer frightening  
Positive Reinforcement: strengthening behaviour and causing it to occur more frequently by rewarding it  
Negative Reinforcement: causing behaviour to occur more frequently by removing a noxious stimulus when desired behaviour occurs  
Extinction: causing a behaviour to diminish by not rewarding it  
Punishment (aversion therapy): causing a behaviour to diminish by applying a noxious stimulus | Individuals with motivation to change and specific symptoms that are amenable to change  
Global areas of dysfunction such as personality disorder are difficult to treat with behavioural therapy | Usually short term (weeks-months) |
| **Cognitive Therapy**                 | Depression, anxiety, panic disorder, personality disorders, and somatoform disorders | Moods/emotions are influenced by one’s thoughts and psychiatric disturbances are often caused by habitual errors in thinking  
Therapy helps patient make explicit their inaccurate automatic thoughts and correct assumptions with a more balanced perspective  
Uses thought records (often charts with column headings including “situation,” “feeling,” “thought,” “cognitive distortion”) to help monitor thoughts, the situations they occur in, and the feelings they might provoke due to their underlying cognitive errors | Motivated patients who will comply with homework, openness to changing core beliefs | First course - usually 15-25 wk  
Maintenance therapy can be carried over years |
| **Cognitive Behavioural Therapy**     | Most mental health disorders including: mood anxiety, OCD, personality, eating, substance use, psychotic disorders | Combines theory and method from Cognitive and Behavioural therapies to teach the patient to change connections between thinking patterns, habitual behaviours, and mood/anxiety problems | Individuals with motivation to change and are able to participate in homework | Typically 6-18 wk, 1 hr sessions  
Maintenance sessions can be added over time |
| **Dialectical Behavioural Therapy**   | Borderline Personality Disorder | Therapy that combines CBT techniques with Buddhist Zen mindfulness practices and dialectical philosophy  
Focuses on 4 types of skills: mindfulness, emotion regulation, interpersonal effectiveness, and distress tolerance  
Involves 4 components: individual therapy, group skills training, phone consultations, and a consultation team | Patients with severe problems of emotional dysregulation, impulsivity, and self-harm  
Patients with borderline personality disorder or borderline personality trait | Typically 1 yr |
| **Motivational Interviewing**         | Substance use disorders | Spirit of MI (CAPE): Compassion, Acceptance, Partnership, Evocation  
Principles of MI (RULE): Resist “righting reflex”, Understand client and their reasons for change, Listen, Empower by conveying hope and supporting autonomy  
Techniques of MI (OARS): Open-ended questions, Affirmations to validate client, Reflections (the skill of accurate empathy), Summaries to help client organize self | Patients with problematic substance use, maladaptive behaviour patterns (therapy disengagement, medication noncompliance, poor health habits) | Brief interventions (efficacy with as little as 15 min, single sessions), better result with more sessions  
Addiction is a chronic condition, often need boosters over time |
| **Motivational Enhancement Therapy (MET)** | Techniques can be applied to facilitate behavioural change in most psychological problems | | | MET = 4 sessions |
Other Therapies

- group psychotherapy
  - aims to promote self-understanding, acceptance, social skills
- family therapy
  - family system considered more influential than individual, especially for children

Mindfulness-Based Cognitive Therapy (MBCT)/stress reduction (MBSR)

- derived from Buddhist meditative and philosophical practices; aims to help people attend to thoughts, behaviours, and emotions in the moment and non-judgmentally using guided breathing exercises. Emerging evidence for treating adjustment disorder, MDD, anxiety, pain disorders, insomnia, substance relapse prevention
- narrative psychotherapy
  - an integrative approach that attempts to understand the patient’s experience as a whole
  - hypnosis
  - mixed evidence for treatment of pain, phobias, anxiety, and smoking cessation

Pharmacotherapy

Antipsychotics

- “antipsychotics” and “neuroleptics” are terms used interchangeably
- overall mechanism of action: block, to varying degrees, dopamine activity in target brain pathways
- indications: for managing agitation, sleep, psychosis and mania reduction, mood stabilizing - used in schizophrenia and other psychotic disorders, mood disorders with or without psychosis, violent behaviour, autism, Tourette’s, somatoform disorders, dementia, OCD
- onset: immediate calming effect and decrease in agitation; thought disorder responds in 2-4 wk
- rational use
  - no reason to combine antipsychotics
  - choosing an antipsychotic
    - all antipsychotics are equally effective, except for clozapine (considered to be most effective in treatment-refractory psychosis)
    - atypical antipsychotics (SGA) are as effective as typical (first generation) antipsychotics but are thought to have better side effect profiles
    - choose a drug that the patient has responded to in the past or that was used successfully in a family member
- route: PO, short-acting or long-acting depot IM injections, sublingual
- if no response in 4-6 wk, switch drugs; if response, titrate dose
- duration: minimum 6 mo, usually for life

Long-Acting Preparations

- antipsychotics formulated in oil for IM injection
- received on an outpatient basis
- indications: individuals with schizophrenia or other chronic psychosis who relapse because of non-adherence
- dosing: start at low dosages, then titrate every 2-4 wk to maximize safety and minimize side effects
- should be exposed to oral form prior to first injection
- side effects: risk of EPS, parkinsonism, increased risk of NMS

Canadian Guidelines for the Treatment of Acute Psychosis in the Emergency Setting

- haloperidol 5 mg IM ± lorazepam 2 mg IM
- loxapine 25 mg ± lorazepam 2 mg IM
- olanzapine 2.5-10 mg (PO, IM, quick dissolve)
- risperidone 2 mg (M-tab, liquid)

Two Year Randomized Controlled Trial and Follow-Up Of Dialectical Behaviour Therapy (DBT) vs. Treatment by Experts for Suicidal Behaviours and Borderline Personality Disorder

**Purpose**: To determine how DBT compares with non-behavioural psychotherapy.

**Methods**: RCT involving 1 year of DBT or of non-behavioural therapy, followed by 1-year follow-up period. Women with recent suicidal and self-injurious behaviours meeting DSM criteria and matched to various demographic data were included. Primary outcome was trimester assessments of suicidal behaviour, emergency services use and general psychological well-being.

**Results**: Patients receiving DBT were half as likely to attempt suicide, required less hospitalization for suicidal ideation, had fewer medical risks for suicide attempts, were less likely to drop out of therapy, and had few emergency room visits for suicidal ideation.

**Conclusions**: DBT is effective in reducing suicidal behaviour in patients with borderline personality disorder.

</table>

### Advantages
- Lower incidence of EPS than typical antipsychotics at lower doses (<8 mg)
- Associated with less weight gain compared to clozapine and olanzapine
- Better overall efficacy compared to haloperidol
- Well tolerated
- Low incidence of EPS and TD
- Mood stabilizing
- Most effective for treatment-resistant schizophrenia
- Does not worsen tardive symptoms; may treat them
- Approximately 50% of patients benefit, especially paranoid patients and those with onset after 20 yr
- Less weight gain and risk of metabolic syndrome compared to olanzapine
- A lower incidence of EPS compared to haloperidol

### Disadvantages
- SE: insomnia, agitation, EPS, H/A, anxiety, prolactin, postural hypotension, constipation, dizziness, weight gain
- Highest risk of EPS among atypicals (still lower than high-potency typicals)
- SE: mild sedation, insomnia, dizziness, minimal anticholinergic, early AST and ALT elevation, restlessness
- High risk of metabolic effects (weight gain, DM, hyperlipidemia)
- SE: H/A, sedation, dizziness, constipation
- Most sedating of first line atypicals
- SE: drowsiness/sedation, hyperactivation, tachycardia, myocarditis, cardiomyopathy, dizziness, EPS, NAMS
- 1% agranulocytosis

### Comments
- Quick dissolve (Zydis®) used commonly in ER setting for better compliance
- IM form available
- Quick dissolve formulation (Zydos®) used commonly in ER setting for better compliance
- Weekly blood counts for 6 mo, then q2wk
- Do not use with drugs which may cause bone marrow suppression due to risk of agranulocytosis

### Note
- Risk of weight gain: Clozapine > Olanzapine > Quetiapine > Risperidone

---

**Effectiveness of Antipsychotic Drugs in Patients with Chronic Schizophrenia**

**Purpose:** To compare perphenazine with several newer drugs (olanzapine, quetiapine, risperidone, ziprasidone) in patients with chronic schizophrenia.

**Methods:** Randomized, double-blind, active-control trial with median follow-up of 56 mo, involving patients with a diagnosis of schizophrenia (as per DSM-IV criteria) and able to take antipsychotic medications (as determined by study doctors). Patients were assigned to receive 1-4 capsules daily of olanzapine (20.1 mg), quetiapine (643.4 mg), risperidone (6.9 mg), perphenazine (30.8 mg), or ziprasidone (112.8 mg), with dosage at the discretion of the study doctor. Main outcome was discontinuation of treatment for any cause.

**Results:** 1,432 patients were included. The olanzapine group had statistically significant lower rate of discontinuation for any cause (H4%) from all others (quetiapine – 82%, risperidone – 81%, perphenazine – 79%, ziprasidone – 98%). There were no significant differences in time until discontinuation due to intolerable side effects; however, olanzapine was associated with a significantly higher rate of metabolic side effects.

**Conclusion:** The majority of patients in each group discontinued treatment due to inefficacy and intolerable side effects; for other reasons. Olanzapine was most effective in terms of lowest rates of discontinuation. Efficacy of conventional antipsychotic agent perphenazine was similar to quetiapine, risperidone and olanzapine.

**Anticholinergic Effects**

- Red as a beet
- Hot as a hare
- Dry as a bone
- Blined as a bat
- Mad as a hatter

**Note:** high potency antipsychotics (e.g. haloperidol) have low doses, while low potency antipsychotics (e.g. chlorpromazine) have high doses
Anticholinergic Agents

- benztropine (Cogentin®) 2 mg PO, IM, or IV OD (1-6 mg)
- amantadine (Symmetrel®) 100 mg PO bid (100-400 mg)
- diphenhydramine (Benadryl®) 25-50 mg PO/IM qid
- do not always prescribe with neuroleptics
- give anticholinergic agents only if at high risk for acute EPS or if acute EPS develops
- do not give these for tardive syndromes because they worsen the condition

Antidepressants

- onset of effect
  - relief of neurovegetative/physical symptoms: 1-3 wk
  - relief of emotional/cognitive symptoms: 2-6 wk
- taper TCAs slowly (over weeks-months) because they can cause withdrawal reactions
- tapering of any antidepressant is usually required and is based on the medication’s half-life and the patient’s individual sensitivity (e.g. fluoxetine does not require a slow taper due to long half life)

Table 17. Side Effects of Antipsychotics

<table>
<thead>
<tr>
<th>System</th>
<th>Side Effects</th>

<tr>
<td>Endocrine</td>
<td>Metabolic syndrome</td>
</tr>
</tbody>
</table>

Neuroleptic Malignant Syndrome

- psychiatric emergency
  - due to massive dopamine blockade; increased incidence with high potency and depot neuroleptics
- risk factors
  - medication factors: sudden increase in dosage, starting a new drug
  - patient factors: medical illness, dehydration, exhaustion, poor nutrition, external heat load, male, young adults
- clinical presentation
  - mental status changes (usually occur first), fever, autonomic reactivity, rigidity
  - develops over 24-72 h
  - labs: increased creatine phosphokinase, leukocytosis, myoglobinuria
- treatment: supportive - discontinue drug, hydration, cooling blankets, dantrolene (hydrantoin derivative, used as a muscle relaxant), bromocriptine (DA agonist)
- mortality: 5%

Extrapyramidal Symptoms

- incidence related to increased dose and potency
- acute (early-onset; reversible) vs. tardive (late-onset; often irreversible)

Table 18. Extrapyramidal Symptoms

<table>
<thead>
<tr>
<th>Onset</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Acute: within 5 d Tardive: &gt;90 d</td>
<td>Acute: benztropine or diphenhydramine</td>
</tr>
<tr>
<td>Acute: within 10 d Tardive: &gt;90 d</td>
<td>Acute: lorazepam, propranolol, diphenhydramine; reduce or change neuroleptic to lower potency</td>
</tr>
<tr>
<td>Acute: within 30 d Tardive: &gt;90 d</td>
<td>Acute: benzotripe (or ben diazepine if side effects); reduce or change neuroleptic to lower potency</td>
</tr>
<tr>
<td>Purposeless, constant movements, involving facial and mouth musculature, or less commonly – the limbs</td>
<td>Tardive: no good treatment; may try clozapine; discontinue drug or reduce dose</td>
</tr>
</tbody>
</table>

Metabolic and Cardiovascular Adverse Effects Associated with Antipsychotic Drugs

- important side effect of antipsychotics
- consider getting ECG prior to initiating new medication and to monitor side effects
- typical: chlorpromazine and haloperidol warrant cardiac monitoring
- Atypicals: ziprasidone has the highest risk among atypicals, clozapine also warrant monitoring

Selective Serotonin Reuptake Inhibitors (SSRIs) vs. Other Antidepressants for Depression

**Conclusion**: There is no clinically significant difference in effectiveness of SSRIs vs. TCAs. The standardized effect size for SSRIs and related drugs was that of 0.035 (95% CI -0.006 to 0.076; p< 0.001).

**Methods**: Systematic review of RCTs comparing the efficacy of SSRIs with other kinds of antidepressants (e.g., tricyclic antidepressants (TCAs)) for management of depressive disorders.

**Results**: Ninety-eight trials were included, with 5,044 patients treated with an SSRI or related drug, and 4,510 with an alternate antidepressant. The outcome measures assessed were measures of depression severity.

**Conclusions**: There is no clinically significant difference in effectiveness of SSRIs vs. TCAs. Treatment decisions should consider relative patient acceptability, toxicity, and cost.
must be vigilant over the first 2 wk of therapy; neurovegetative symptoms may start to resolve while emotional and cognitive symptoms may not (patients may be particularly at risk for suicidal behaviour during this time; in children/adolescents, paroxetine and venlafaxine may increase restlessness and suicide ideation, so are generally not prescribed)

- treatment of bipolar depression
  - patients with bipolar disorder should only be treated with an antidepressant if combined with a mood stabilizer or antipsychotic; monotherapy with antidepressants is not advisable as the depression can turn into mania

### Table 19. Common Antidepressants

<tr>
<td></td>
<td>Desvenlafaxine (Pristiq®)</td>
<td>50</td>
<td>50-100</td>
<td>Useful for depression, seasonal depression</td>
</tr>
<tr>
<td></td>
<td>duloxetine (Cymbalta®)</td>
<td>30</td>
<td>30-60</td>
<td>Causes less sexual dysfunction (may reverse effects of SSRIIs/SNRIs), weight gain, and sedation</td>
</tr>
<tr>
<td></td>
<td>sertraline (Zoloft®)</td>
<td>10</td>
<td>50-100</td>
<td>Increased risk of seizures at higher doses</td>
</tr>
<tr>
<td></td>
<td>tranylcypromine (Parnate®)</td>
<td>30</td>
<td>10-60</td>
<td>Contraindicated with history of seizure, stroke brain tumour, brain injury, closed head injury</td>
</tr>
<tr>
<td>MAOI</td>
<td>phenelzine (Nardil®)</td>
<td>45</td>
<td>60-90</td>
<td>Useful for moderate/severe depression that does not respond to SSRI, atypical depression</td>
</tr>
<tr>
<td></td>
<td>tranylcypromine (Parnate®)</td>
<td>30</td>
<td>10-60</td>
<td>Important to specify formulation, as available in IR, SR, XL (longest)</td>
</tr>
<tr>
<td>MAOI</td>
<td>moclobemide (Manerix®)</td>
<td>300</td>
<td>300-600</td>
<td>Useful for depression unresponsive to other therapies</td>
</tr>
<tr>
<td>NASSA</td>
<td>mirtazapine (Remeron®)</td>
<td>15</td>
<td>15-45</td>
<td>Useful in depression with prominent features of insomnia, agitation, or cachexia</td>
</tr>
<tr>
<td>NDRI</td>
<td>bupropion (Wellbutrin®)</td>
<td>100</td>
<td>300-450</td>
<td>Useful as mood stabilizer or in combination with an antidepressant</td>
</tr>
</tbody>
</table>

MAOI = monoamine oxidase inhibitors; NASSA = noradrenergic and specific serotonin antagonists; NDRI = norepinephrine and dopamine reuptake inhibitors; RIMA = reversible inhibition of MAO-A; SNRI = serotonin and norepinephrine reuptake inhibitors; SSRI = selective serotonin reuptake inhibitors; TCA = tricyclic antidepressants

### Treatment Approach for Depression

- optimization: ensuring adequate drug doses for the individual
- augmentation: the addition of a medication that is not considered an antidepressant to an antidepressant regimen (e.g. thyroid hormone, lithium, atypical antipsychotics (specifically: olanzapine, risperidone, aripiprazole))
- combination: the addition of another antidepressant to an existing treatment regimen (e.g. the addition of bupropion to an SSRI or SNRI)
- substitute: change in the primary antidepressant (within or outside a class)
- note: it is important to fully treat depression symptoms in order to decrease relapse rates and severity
<table>

</tbody>
</table>

**Serotonin Syndrome**
- thought to be due to over-stimulation of the serotonergic system
- can result from medication combinations such as SSRI+MAOI, SSRI+tryptophan, MAOI+meperidine, MAOI+tryptophan
- rare but potentially life-threatening adverse reaction to SSRIs, especially when switching from an SSRI to an MAOI
- symptoms include nausea, diarrhea, palpitations, chills, restlessness, confusion, and lethargy but can progress to myoclonus, hyperthermia, rigor and hypertonicity
- treatment: discontinue medication and administer emergency medical care as needed
- important to distinguish from NMS

**Discontinuation Syndrome**
- caused by the abrupt cessation of an antidepressant; most commonly with paroxetine, fluvoxamine, and venlafaxine (drugs with shortest half-lives)
- symptoms usually begin within 1-3 d and include: anxiety, insomnia, irritability, mood lability, nausea/vomiting, dizziness, headache, dystonia, tremor, chills, fatigue, lethargy, and myalgia
- treatment: symptoms may last between 1-3 wk, but can be relieved within 24 h by restarting antidepressant therapy at the same dose the patient was taking and initiating a slow taper over several weeks
- consider using a drug with a longer half-life such as fluoxetine
Mood Stabilizers

General Prescribing Information
- examples: lithium, lamotrigine, divalproex, carbamazepine
- used in conjunction with atypical antipsychotics for managing episodes of bipolar disorder - depression, mania, stabilization
- vary in their ability to "treat" (reduce symptoms acutely) or "stabilize" (prevent relapse and recurrence)
- manic and depressive symptoms; multi-agent therapy is common
- before initiating, get baseline: CBC, ECG (if patient >45 yr old or cardiovascular risk), urinalysis, BUN, Cr, electrolytes, TSH
- before initiating lithium: screen for pregnancy, thyroid disease, seizure disorder, neurological, renal, cardiovascular diseases
- full effects not for 2-4 wk; thus may need acute coverage with benzodiazepines or antipsychotics

Specific Prescribing Information
- detailed pharmacological guidelines available online from the Canadian Network for Mood and Anxiety Treatments (CANMAT) and International Society for Bipolar Disorders (ISBD)
- for clinical information for treating bipolar disorder (see Mood Disorders, PS9)

</tbody>
</table>

Mode of Action
- Unknown
- Therapeutic response within 7-14 d
- May inhibit 5-HT3 receptors
- May potentiate DA activity

Dosage
- Adult: 600-1500 mg/d
- Geriatric: 150-600 mg/d
- Usually daily dosing
- Starting: 12.5-15 mg/d
- Daily dose: 100-200 mg/d
- Dose adjusted in patients taking other anticonvulsants
- Note: very slow titration due to risk of Stevens-Johnson Syndrome

Therapeutic Level
- Adult: 0.8-1.0 mmol/L (1.0-1.25 mmol/L for acute mania)
- Geriatric: 0.5-0.8 mmol/L
- Therapeutic plasma level not established
- Dosing based on therapeutic response
- 17-50 mmol/L
- Therapeutic levels are for seizure prophylaxis
- 350-700 µmol/L

Monitoring
- Monitor serum levels until therapeutic (always wait 12 h after dose)
- Then monitor b.i.w. or monthly until a steady state is reached, then q2mo
- Monitor thyroid function q6mo, creatinine q6mo, urinalysis q1yr
- Monitor for suicidality, particularly when initiating treatment
- LFTs weekly x 1 mo, then monthly, due to risk of liver dysfunction
- Watch for signs of liver dysfunction: nausea, edema, malaise
- Monitor levels to confirm adherence
- Weekly blood counts for first month, due to risk of agranulocytosis
- Watch for signs of blood dyscrasias: fever, rash, sore throat, easy bruising

Side Effects
- GI: N/V, diarrhea, stomach pain
- GU: polyuria, polydipsia, GN, renal failure, nephrogenic DI
- CNS: fine tremor, lethargy, fatigue, headache
- Hematologic: reversible leukocytosis
- Other: teratogenic (Estbeen’s anomaly), weight gain, edema, paresthesia, hypothyroidism, hair thinning, muscle weakness, ECG changes
- GI: liver dysfunction, N/V, diarrhea, nausea, edema, malaise
- Glutamatergic: reversible drug because of risk of Stevens-Johnson syndrome, increased lamotrigine levels = increased risk of rash
- Anxiety

Interactions
- NSAIDs decrease clearance
- OCP
- OCP
Lithium Toxicity
- clinical diagnosis as toxicity can occur at therapeutic levels
- common causes: overdose, sodium/fluid loss, concurrent medical illness
- clinical presentation
  - GI: severe nausea/vomiting and diarrhea
  - cerebellar: ataxia, slurred speech, lack of coordination
  - cerebral: drowsiness, myoclonus, tremor, upper motor neuron signs, seizures, delirium, coma
- management
  - discontinue lithium for several doses and begin again at a lower dose when lithium level has fallen to a non-toxic range
  - serum lithium levels, BUN, electrolytes
  - saline infusion
  - hemodialysis if lithium >2 mmol/L, coma, shock, severe dehydration, failure to respond to treatment after 24 h, or deterioration

Anxiolytics
- anxiolytics mask or alleviate symptoms; they do not cure them
- indications
  - short-term treatment of transient forms of anxiety disorders, insomnia, alcohol withdrawal (especially delirium tremens), barbiturate withdrawal, organic brain syndrome (acute agitation in delirium), EPS and akathisia due to antipsychotics, seizure disorders, musculoskeletal disorders
- relative contraindications
  - major depression (except as an adjunct to other treatment), history of drug/alcohol abuse, caution in pregnancy/breastfeeding
- mechanism of action
  - benzodiazepines: potentiate binding of GABA to its receptors; results in decreased neuronal activity
  - buspirone: partial agonist of 5-HT1A receptors

Benzodiazepines
- should be used for limited periods (weeks-months) to avoid dependence
- all benzodiazepines are sedating; be wary with use in the elderly
- have similar efficacy, so choice depends on half-life, metabolites and route of administration, OD or bid
- taper slowly over weeks-months because they can cause withdrawal reactions
  - low dose withdrawal: tachycardia, HTN, panic, insomnia, anxiety, impaired memory and concentration, perceptual disturbances
  - high dose withdrawal: hyperpyrexia, seizures, psychosis, death
- avoid alcohol because of potentiation of CNS depression; caution with drinking and driving/machinery use
- side effects
  - CNS: drowsiness, cognitive impairment, reduced motor coordination, memory impairment
  - physical dependence, tolerance
- withdrawal
  - symptoms: anxiety, insomnia, autonomic hyperactivity (less common)
  - onset: 1-2 d (short-acting), 2-4 d (long-acting)
  - duration: weeks-months
  - complications with above 50 mg diazepam/day: seizures, delirium, arrhythmias, psychosis
  - management: taper with long-acting benzodiazepine
  - similar to but less severe than alcohol withdrawal; can be fatal
- overdose
  - commonly used drug in overdose
  - overdose is rarely fatal
  - benzodiazepines are more dangerous and may cause death when combined with alcohol, other CNS depressants or TCAs

Benzodiazepine Antagonist – Flumazenil (Anexate®)
- use for suspected benzodiazepine overdose
- specific antagonist at the benzodiazepine receptor site

**Somatic Therapies**

**Electroconvulsive Therapy**

- Various methodological improvements have been made since the first treatment in 1938 to reduce adverse effects.
- Modern ECT: induction of a generalized seizure using an electrical pulse through scalp electrodes while the patient is under general anesthesia with a muscle relaxant.
- Considerations: unilateral vs. bilateral electrode placement, pulse rate, dose, number and spacing of treatments.
- Usual course is 6-12 treatments, 2-3 treatments per week.
- **Indications**
  - Depression refractory to adequate pharmacological trial (MDD or Bipolar I depression).
  - High suicide risk.
  - Medical risk in addition to depression (dehydration, electrolytes, pregnancy).
  - Previous good response to ECT.
  - Familial response to ECT.
  - Elderly.
  - Psychotic depression.
  - Catatonic features.
  - Marked vegetative features.
  - Acute schizophrenia unresponsive to medication.
  - Mania unresponsive to medications.
  - OCD refractory to conventional treatment.

- **Side effects**: Risk of anesthesia, memory loss (may be retrograde and/or anterograde, tends to resolve by 6-9 mo), permanent impairment (controversial), headaches, myalgias.
- Unilateral ECT causes less memory loss than bilateral but may not be as effective.
- **Contraindications**: Increased intracranial pressure, recent (<2 wk) MI (not absolute but requires special monitoring).

**Repetitive Transcranial Magnetic Stimulation (rTMS)**

- Noninvasive production of focal electrical currents in select brain areas using magnetic induction.
- **Indications**: Strong evidence for treatment-resistant depression, pain disorders; possibly efficacious for anxiety disorders, eating disorders, substance use disorders.
- **Adverse effects**: Common – transient local discomfort, hearing issues, cognitive changes; rare – seizure, syncope, mania induction.

**Magnetic Seizure Therapy (MST)**

- Seizure induction by magnetic current induction rather than direct stimulation.
- Early studies demonstrate efficacy for depression as well as anxiety, reduced memory side effects vs. ECT.

**ECT in Society**

Prior to the 1940s, ECT was performed without the use of muscle relaxants, resulting in seizures with full-scale convulsions and rare but serious complications such as vertebral and long-bone fractures. This practice may have led to negative societal perceptions of ECT, further perpetuated by barbaric depictions in popular culture. Despite ongoing stigmatization, ECT as it is practiced today is an effective and safe option for patients struggling with mental illness.

**Efficacy of ECT in Depression: A Meta-Analytic Review**

J of ECT 2004; 20:13-20

**Purpose**: To analyze the efficacy of electroconvulsive therapy (ECT) in depression.

**Methods**: Meta-analysis of randomized and non-randomized control trials, comparing ECT to simulated ECT and placebo in individuals with a diagnosis of unipolar or bipolar depression. Main outcome was the Hamilton Depression Rating scale.

**Results**: ECT was found to be superior to simulated ECT, placebo, tricyclic antidepressants (TCAs), monoamine oxidase inhibitors (MAOIs), and antideperessants in general.

**Conclusion**: ECT is an valid treatment modality, including in severe and treatment-resistant depression cases.
Neurosurgical Treatments

Ablative/Lesion Procedures
- used for intractable MDD or OCD, efficacy ranges from 25-75% depending on procedure
- adverse effects: related to lesion location and size; high risk of suicide in those who are not helped by surgery

Deep Brain Stimulation
- placement of small electrode leads in specific brain areas to alter neuronal signaling, usually for intractable MDD
- response rates (>50% symptom reduction) of 40-70%, adverse effects related to surgical risks and poor treatment response

Vagus Nerve Stimulation
- direct, intermittent electrical stimulation of left cervical vagus nerve via implanted pulse generator
- used for chronic, recurrent MDD that has failed previous therapy and ECT; slow onset, approximately 30% response rate at 1 yr

Other Therapy Modalities

Phototherapy (Light Box Therapy)
- bright light source exposure, best in morning, for 30-60 min (usually 10,000 lux)
- proposed mechanisms: reverses pathological alterations in circadian rhythm through action on suprachiasmatic nucleus
- indications: SAD, non-seasonal depression (as augmentation), sleep disorders
- adverse effects: mania induction, reaction with photosensitizing drug or photosensitive eye or skin conditions

Aerobic Exercise
- moderate-intense aerobic exercise is associated with acute increased secretion of serotonin, phenethylamine, BDNF, endogenous opioids and cannabinoids (likely this combination is what contributes to the “runner’s high”)
- long term increases grey matter in multiple areas, as well as improvements in cognition, memory, and stress tolerance
- indications: Monotherapy for mild-moderate MDD, Adjunctive therapy for moderate-severe MDD; research suggests 30 min of supervised moderate-intensity exercise at least 3 times weekly for a minimum of 9 wk is effective
- may be helpful in PTSD, schizophrenia

* Schedule 1 Facilities: Able to provide intensive inpatient and outpatient care

### Consent

- see Ethical, Legal, and Organizational Medicine, ELOM7

### Community Treatment Order (CTO)

- purpose: a CTO orders a person suffering from a serious mental disorder to receive treatment and supervision in the community. Based on a comprehensive plan outlining medications, appointments, and other care believed necessary to allow the person to live in the community (vs. in a psychiatric facility, where things are more restrictive)
- intended for those who:
  - due to their serious mental disorder, experience a pattern of admission to a psychiatric facility where condition is usually stabilized
  - after being released, these patients often lack supervision and stop treatment, leading to destabilization
  - due to the destabilization of their condition, these patients usually require re-admission to hospital
  - if CTO violated (e.g. treatment not taken), patient brought in by police to hospital for treatment as per CTO
- criteria for a physician to issue a CTO:
  - patient with a prior history of hospitalization
  - a community treatment plan for the person has been made
  - examination by a physician within the previous 72 h before entering into the CTO plan
  - ability of the person subject to the CTO to comply with it
  - consultation with a rights advisor and consent of the person or the person's substitute decision maker
- CTOs are valid for 6 mo unless they are renewed or terminated at an earlier date such as
  - where the person fails to comply with the CTO
  - when the person or his/her substitute decision-maker withdraws consent to the community treatment plan
- CTO process is consent-based and all statutory protections governing informed consent apply
- the rights of a person subject to a CTO include
  - the right to a review by the Consent and Capacity Board with appeal to the courts each time a CTO is issued or renewed
  - a mandatory review by the Consent and Capacity Board every second time a CTO is renewed
  - the right to request a re-examination by the issuing physician to determine if the CTO is still necessary for the person to live in the community
  - the right to review findings of incapacity to consent to treatment
  - provisions for rights advice

Approach to the Respiratory Patient

Basic Anatomy Review

Figure 1. Lung lobes and bronchi

Figure 2. Respiration patterns in normal and disease states

Respiration Pattern

Normal

Obstructive (prolonged expiration)
- Asthma, COPD

Bradyynes (slow respiratory rate)
- Drug-induced respiratory depression
- Diabetic coma (nonketotic)
- Increased ICP

Kussmaul's Breathing (fast and deep)
- Metabolic acidosis
- Exercise
- Anxiety

Biot's/Ataxic (irregular with long apneic periods)
- Drug-induced respiratory depression
- Increased ICP
- Brain damage (especially medullary)

Cheyne-Stokes Breathing (changing rates and depths with apneic periods)
- Drug-induced respiratory depression
- Brain damage (especially cerebral)
- CHF
- Uremia

Apneustic (prolonged inspiratory pause)
- Pontine lesion

**Arterial Blood Gases**

- provides information on acid-base and oxygenation status
- see Nephrology, NP15

**Approach to Acid-Base Status**

1. Is the pH acidemic (pH <7.35), alkalemic (pH >7.45), or normal (pH 7.35-7.45)?
2. What is the primary disturbance?
   - metabolic: change in HCO₃⁻ and pH in same direction
   - respiratory: change in HCO₃⁻ and pH in opposite directions
3. Is there appropriate compensation? (see Table 8)
   - metabolic compensation occurs over 2-3 d reflecting altered renal HCO₃⁻ production and excretion
   - respiratory compensation through ventilatory control of P.CO₂ occurs immediately
   - inadequate compensation may indicate a second acid base disorder
Table 8. Expected Compensation for Specific Acid-Base Disorders

<table>
<thead>
<tr>

</tr>
<tr>
<td>Metabolic Alkalosis</td>
<td>↑ 5-7</td>
<td>↑ 10</td>
</tr>
</tbody>
</table>

4. if there is metabolic acidosis, what is the anion gap and osmolar gap?
   - anion gap = [Na⁺]–([Cl⁻]+[HCO₃⁻]); normal ≤10-15 mmol/L
   - osmolar gap = measured osmolarity – calculated osmolarity = measured – (2[Na⁺] + glucose + urea); normal ≤10 mmol/L

5. if anion gap is increased, is the change in bicarbonate the same as the change in anion gap?
   - if not, consider a mixed metabolic picture

- see Nephrology, NP16 for differential diagnosis of metabolic acidosis and alkalosis
Airway Disease

Pneumonia

- see Infectious Diseases, ID7

Asthma

- see Family Medicine, FM16 and Pediatrics, P82

Definition
chronic inflammatory disorder of the airways resulting in episodes of reversible bronchospasm causing airflow obstruction
associated with reversible airflow limitation and airway hyper-responsiveness to endogenous or exogenous stimuli

Epidemiology
- common, 7-10% of adults, 10-15% of children
- most children with asthma significantly improve in adolescence
- often family history of atopy (asthma, allergic rhinitis, eczema)
- occupational asthma (organic allergies, isocyanates, animals, etc.)
Pathophysiology
• airway obstruction → V/Q mismatch → hypoxemia → ↑ ventilation → ↓ P,CO₂ → ↑ pH and muscle fatigue → ↓ ventilation, ↑ P,CO₂/↓ pH

Signs and Symptoms
• dyspnea, wheezing, chest tightness, cough, sputum
• symptoms usually occur or worsen at night
• symptoms can be paroxysmal or persistent
• signs of respiratory distress
• pulsat paradoxxus

Table 11. Criteria for Determining if Asthma is Well Controlled

</tbody>
</table>

Adapted from: Can Respir J 2012; 19:127-164

Treatment
• environment: avoid triggers
• patient education: features of the disease, goals of treatment, self-monitoring
• pharmacological
  • symptomatic relief in acute episodes: short-acting β₂-agonist, anticholinergic bronchodilators, inhaled corticosteroids, addition of a long acting β₂-agonist
  • long-term maintenance: inhaled/oral corticosteroids, anti-allergic agents, long-acting β₂-agonists (do not use LABA alone), long-acting anticholinergics, methylxanthine, LTRA, anti-IgE antibodies (e.g. omalizumab), anti-IL5 drugs (e.g. mepolizumab)

Emergency Management of Asthma
• see Emergency Medicine, ER29
  1. inhaled β₂-agonist first line (MDI route and spacer device recommended)
  2. systemic steroids (PO or IV if severe)
  3. if severe add anticholinergic therapy ± magnesium sulfate
  4. rapid sequence intubation in life-threatening cases (plus 100% O₂, monitors, IV access)
  5. SC/IV adrenaline if caused by anaphylaxis, IV salbutamol if unresponsive
  6. corticosteroid therapy at discharge
**Chronic Obstructive Pulmonary Disease**

- See Family Medicine, FM16

**Definition**
-progressive and irreversible condition of the lung characterized by chronic obstruction to airflow with many patients having periodic exacerbations, gas trapping, lung hyperinflation, and weight loss
-2 subtypes: chronic bronchitis and emphysema (usually coexist to variable degrees)
-gradual decrease in FEV₁ over time with episodes of acute exacerbations

**Table 13. Clinical and Pathologic Features of COPD**

<table>
<thead>
<tr>
<th>Chronic Bronchitis</th>
<th>Emphysema</th>
</tr>
</thead>
<tbody>
<tr>
<td>Defined Clinically</td>
<td>Defined Pathologically</td>
</tr>
<tr>
<td>Productive cough on most days for at least 3 consecutive months in 2 successive years</td>
<td>Dilation and destruction of air spaces distal to the terminal bronchiole without obvious fibrosis</td>
</tr>
<tr>
<td>Obstruction is due to narrowing of the airway lumen by mucosal thickening and excess mucus</td>
<td>Decreased elastic recoil of lung parenchyma causes decreased expiratory driving pressure, airway collapse, and air trapping</td>
</tr>
</tbody>
</table>

-2 Types
  1. **Cent iacinar** (respiratory bronchiole)
     - Typical form seen in smokers, primarily affects upper lung zones
  2. **Panacinar** (all parts of acinus)
     - Accounts for about 1% of emphysema cases
     - α1-antitrypsin deficiency, primarily affects lower lobes

*Note that both chronic bronchitis and emphysema can exist without obstruction. Only if obstruction is also present is it termed COPD

**Risk Factors**
- smoking is #1 risk factor
- others
  - environmental: air pollution, occupational exposure, exposure to wood smoke or other biomass fuel for cooking
  - treatable factors: α1-antitrypsin deficiency, bronchial hyperactivity
  - demographic factors: age, family history of atopy, male sex, history of childhood respiratory infections, low socioeconomic status

- Inherited di order of defective production of α1-antitrypsin, a protein produced by hepatocytes. Acts in the alveolar tissue by inhibiting the action of proteases from destroying alveolar tissue. When deficient, proteases can destroy lung alveoli resulting in emphysema

- Toronto Notes 2018

<td>ICS monotherapy has been shown to increase the incidence of pneumonia in COPD; ICS should only be used with a LABA in combination in patients with a history of exacerbations</td>
</tr>
<tr>
<td>Oral steroids are important when treating exacerbations; chronic systemic glucocorticoids are generally not recommended due to unfavourable benefit to risk ratio</td>
<td></td>
</tr>
<tr>
<td>Surgical</td>
<td>Lung volume reduction surgery (resection of emphysematous parts of lung, associated with higher mortality if FEV₁ &lt; 20%), lung transplant</td>
</tr>
<tr>
<td>Other</td>
<td>Patient education, eliminate respiratory irritants/allergens (occupational/environmental), exercise rehabilitation to improve physical endurance</td>
</tr>
</tbody>
</table>

- Note that the distinction between “blue bloaters” and “pink puffers” is more of historical than practical interest as most COPD patients have elements of both.

**GOLD Classification of the Severity of COPD**

- **GOLD 1** Mild FEV₁ >80% of predicted
- **GOLD 2** Moderate 50% <FEV₁ <80% of predicted
- **GOLD 3** Severe 30% < FEV₁ <50% of predicted
- **GOLD 4** Very Severe FEV₁ <30% of predicted

**Influenza Vaccine for Patients with Chronic Obstructive Pulmonary Disease**

- Study: Cochrane systematic review. 11 RCTs included, 6 specifically in COPD patients.
- Population: 7,971 patients with acute COPD exacerbations.
- Intervention: Oral or parenteral corticosteroids vs. placebo.
- Outcome: Treatment failure, risk of relapse, time to next COPD exacerbation, length of hospital stay, lung function at end of treatment.
- Results: Systemic corticosteroids reduced the risk of treatment failure by over half compared with placebo in nine studies (n = 917) with median treatment duration 14.6 days, OR 0.49 (95% CI 0.35-0.68). The evidence was graded as high quality and it would have been necessary to treat nine people (weighting mean difference (WMD) 0.37, 95% CI 0.04-0.70) to prevent one failure. There was no increased risk of local and transient adverse events.

**Conclusion:** There appears to be a reduction in influenza-related infections, as well as exacerbations in patients with COPD receiving the vaccine.

**Systemic Corticosteroids for Acute Exacerbations of Chronic Obstructive Pulmonary Disease**

- Study: Cochrane systematic review. 11 RCTs included, 6 specifically in COPD patients.
- Population: 1,787 patients with acute COPD exacerbations.
- Intervention: Oral or parenteral corticosteroids vs. placebo.
- Outcome: Treatment failure, risk of relapse, time to next COPD exacerbation, length of hospital stay, lung function at end of treatment.
- Results: Systemic corticosteroids reduced the risk of treatment failure by over half compared with placebo in nine studies (n = 917) with median treatment duration 14.6 days, OR 0.49 (95% CI 0.35-0.68). The evidence was graded as high quality and it would have been necessary to treat nine people (weighting mean difference (WMD) 0.37, 95% CI 0.04-0.70) to prevent one failure. There was no increased risk of local and transient adverse events.

**Conclusion:** There is high-quality evidence to support treatment of exacerbations in COPD with systemic corticosteroids by the oral or parenteral route in reducing the likelihood of treatment failure and relapse by 1.14, shortening length of stay in hospital exacerbations not requiring assisted ventilation in ICU and giving early improvement in lung function and symptoms. There is no evidence of benefit for parenteral treatment compared with oral treatment with corticosteroid treatment as a result of relapse or mortality or any secondary outcomes.

**Conclusion:** There is high-quality evidence to support treatment of exacerbations in COPD with systemic corticosteroids by the oral or parenteral route in reducing the likelihood of treatment failure and relapse by 1.14, shortening length of stay in hospital exacerbations not requiring assisted ventilation in ICU and giving early improvement in lung function and symptoms. There is no evidence of benefit for parenteral treatment compared with oral treatment with corticosteroid treatment as a result of relapse or mortality or any secondary outcomes.
Acute Exacerbations of COPD

**Definition**
- Sustained (>48 h) worsening of dyspnea, cough, or sputum production leading to an increased use of medications
- In addition, defined as either purulent or non-purulent (to predict need for antibiotic therapy)

**Etiology**
- Viral URTI, bacteria, air pollution, CHF, PE, MI must be considered

**Management**
- ABCs, consider assisted ventilation if decreasing LOC or poor ABGs
- O₂: target 88-92% SaO₂ for CO₂ retainers
- SABA + anticholinergic, e.g. salbutamol and ipratropium bromide via nebulizers × 3 back-to-back q15min
- Systemic corticosteroids: IV solumedrol or oral prednisolone or oral prednisone
- Antibiotics for exacerbations with increased sputum production and at least one of the following:
  - Increased dyspnea or sputum purulence
  - Simple exacerbation (no risk factors): amoxicillin, 2nd or 3rd generation cephalosporin, macrolide, or TMP/SMX
  - Complicated exacerbation (one of: FEV₁ ≤50% predicted, >4 exacerbations per year, ischemic heart disease, home O₂ use, chronic oral steroid use): fluoroquinolone or β-lactam + β-lactamase inhibitor (amoxicillin/clavulanate)
- Post exacerbation: rehabilitation with general conditioning to improve exercise tolerance
- ICU admission
- For life-threatening exacerbations
- Ventilatory support
- Non-invasive: NIPPV, BiPAP
- Conventional mechanical ventilation

**Prognosis in COPD**

**Prognostic factors**
- Level of dyspnea is the single best predictor
- Development of complications, e.g. hypoxemia or cor pulmonale
- 5 yr survival
- FEV₁ < 1 L = 50%
- FEV₁ < 0.75 L = 33%

**BODE index for risk of death in COPD**
- Greater score = higher probability the patient will die from COPD; score can also be used to predict hospitalization
- 10 point index consisting of four factors:
  - Body mass index (BMI): <21 (+1 point)
  - Obstruction (FEV₁): 50-64% (+1), 36-49% (+2), <35% (+3)
  - Dyspnea (MRC scale): walks slower than people of same age on level surface, stops occasionally (+1), stops at 100 yards or a few minutes on the level (+2), too breathless to leave house or breathless when dressing/undressing (+3)
  - Exercise capacity (6 min walk distance): 250-349 m (+1), 150-249 m (+2), <149 m (+3)

**Results**
- In four studies there was no difference in risk of treatment failure between short-duration and longer-duration treatment.
- Conclusions: Prevalence of PE in patients hospitalized for COPD exacerbation of unknown origin is 25%. Therefore, all patients presenting to hospital with COPD exacerbation without obvious cause require PE workup (Doppler or CTA – decision of which to use depends on pre-test probability of the patient).
Bronchiectasis

Definition
- irreversible dilatation of airways due to inflammatory destruction of airway walls resulting from persistently infected mucus
  - usually affects medium sized airways
- *P. aeruginosa* is the most common pathogen; *S. aureus*, *H. influenzae*, and nontuberculous mycobacteria also common

<table>
<thead>
<tr>
<th>Table 16. Etiology and Pathophysiology of Bronchiectasis</th>

</tr>
<tr>
<td>Pertussis</td>
</tr>
<tr>
<td>Allergic bronchopulmonary aspergillosis</td>
</tr>
<tr>
<td>Nontuberculous mycobacterium (NTM)</td>
</tr>
</tbody>
</table>

Signs and Symptoms
- chronic cough, purulent sputum (but 10-20% have dry cough), hemoptysis (can be massive), recurrent pneumonia, local crackles (inspiratory and expiratory), wheezes
- clubbing
- may be difficult to differentiate from chronic bronchitis

Investigations
- PFTs: often demonstrate obstructive pattern but may be normal
- CXR
  - nonspecific: increased markings, linear atelectasis, loss of volume in affected areas
  - specific: “ram tracking” – parallel narrow lines radiating from hilum, cystic spaces, honeycomb like structures
- high-resolution thoracic CT (diagnostic, gold standard)
  - 87-97% sensitivity, 93-100% specificity
  - “signet ring”: dilated bronchi with thickened walls where diameter bronchus > diameter of accompanying artery
- sputum cultures (routine + AFB)
- serum Ig levels
- sweat chloride if cystic fibrosis suspected (upper zone predominant)

Treatment
- vaccination: influenza and pneumococcal vaccination
- chest physiotherapy, breathing exercises, physical exercise
- antibiotics (oral, IV, inhaled): routinely used for mild exacerbations, driven by sputum sensitivity; macrolides may be used chronically for an anti-inflammatory effect
- inhaled antibiotics (tobramycin) used chronically to suppress *Pseudomonas* and reduce exacerbations
- mucolytics (e.g. hypertonic saline, N.B. DNAse only in CF)
- inhaled corticosteroids: decrease inflammation and improve FEV1; however, may increase risk of exacerbations
- oral corticosteroids for acute, major exacerbations
- pulmonary resection: in selected cases with focal bronchiectasis

Cystic Fibrosis

- see *Pediatrics, P82*

Pathophysiology
- chloride transport dysfunction: thick secretions from exocrine glands (lung, pancreas, skin, reproductive organs) and blockage of secretory ducts

Clinical Features
- results in severe lung disease, pancreatic insufficiency, diabetes, and azoospermia
- other manifestations: meconium ileus in infancy, distal ileal obstruction in adults, sinusitis, liver disease
- chronic lung infections
  - *S. aureus*: early
  - *P. aeruginosa*: most common
  - *B. cepacia*: worse prognosis but less common
  - Aspergillus fumigatus

Usually presents in childhood as recurrent lung infections that become persistent and chronic
Interstitial Lung Disease

Investigations
- Sweat chloride test
  - increased concentrations of NaCl and K+ (\([\text{Cl}^-] > 60 \text{ mmol/L}\) suggests diagnosis in children)
  - heterozygotes have normal sweat tests (and no symptoms)
- PFTs
  - early: airflow limitation in small airways
  - late: severe airflow obstruction, hyperinflation, gas trapping, decreased DLco (very late)
- ABGs
  - hypoxemia, hypercapnia later in disease with eventual respiratory failure and cor pulmonale
- CXR
  - hyperinflation, increased pulmonary markings (especially upper lobes)

Treatment
- chest physiotherapy and postural drainage
- pancreatic enzyme replacements, high calorie diet
- bronchodilators (salbutamol ± ipratropium bromide)
- inhaled mucolytic (reduces mucus viscosity), hypertonic saline DNase
- inhaled antibiotics (tobramycin, colistin, aztreonam)
- antibiotics (e.g. ciprofloxacin)
- CFTR potentiators (e.g. Ivacaftor)
- lung transplant

Prognosis
- depends on: infections (cepacia colonization), FEV1, acute pulmonary exacerbations, lung transplant vs. non-lung transplant
- female gender and low socioeconomic class have greater risk of early death

</tbody>
</table>
Signs and Symptoms
- dyspnea, especially on exertion
- nonproductive cough
- crackles (dry, fine, end-inspiratory)
- clubbing (especially in IPF and asbestosis)
- features of cor pulmonale
- note that signs and symptoms vary with underlying disease process
  - e.g. sarcoidosis is seldom associated with crackles and clubbing

Investigations
- CXR/high resolution CT (see Medical Imaging, MI7)
  - usually decreased lung volumes
  - reticular, nodular, or reticulonodular pattern (nodular <3 mm)
  - hilar mediastinal adenopathy (bilateral especially in sarcoidosis)
- PFTs
  - restrictive pattern: decreased lung volumes and compliance
  - normal or increased FEV1/FVC (>70-80%), e.g. flow rates are often normal or high when corrected for absolute lung volume
  - DLCO decreased due to V/Q mismatch (less surface area for gas exchange ± pulmonary vascular disease)
- ABGs
  - hypoxemia and respiratory alkalosis may be present with progression of disease
- other
  - bronchoscopy, bronchoalveolar lavage, lung biopsy
  - ESR, ANA (lupus), RF (RA), serum precipitating antibodies to inhaled organic antigens (hypersensitivity pneumonitis), c-ANCA (GPA), anti-GBM (Goodpasture's)

Unknown Etiologic Agents

IDIOPATHIC PULMONARY FIBROSIS

Definition
- pulmonary fibrosis of unknown cause with usual interstitial pneumonia (UIP) histology (found on biopsy or inferred from CT)
- a progressive, irreversible condition
- DDx: NSIP, COP, desquamative interstitial pneumonitis (DIP), lymphocytic interstitial pneumonitis (LIP), Sjögren's disease

Signs and Symptoms
- commonly presents over age 50, incidence rises with age; males > females
- dyspnea on exertion, nonproductive cough, constitutional symptoms, late inspiratory fine crackles at lung bases, clubbing

Investigations
- labs (nonspecific, autoimmune serology usually negative)
- CXR: reticular or reticulonodular pattern with lower lung predominance; often see honeycombing in advanced disease
- high resolution CT: lower zone peripheral reticular markings, traction bronchiectasis, honeycombing; ground glass, consolidation, or nodules should not be prominent in IPF
- biopsy: rarely for UIP as honeycombing usually makes radiologic diagnosis possible

Treatment
- O2
- pirfenidone and nintedanib can slow disease progression
- lung transplantation for advanced disease
- mean survival of 3-5 yr after diagnosis

SARCOIDOSIS

Definition
- idiopathic non-infectious granulomatous multi-system disease with lung involvement in 90%
- characterized pathologically by non-caseating granulomas
- numerous HLA antigens have been shown to play a role and familial sarcoidosis is now recognized

Epidemiology
- typically affects young and middle-aged patients
- higher incidence among people of African descent and from northern latitudes e.g. Scandinavia, Canada
Signs and Symptoms
- asymptomatic cough, dyspnea, fever, arthralgia, malaise, erythema nodosum, chest pain
- chest exam often normal
- common extrapulmonary manifestations
  - cardiac (arrhythmias, sudden death)
  - eye involvement (anterior or posterior uveitis)
  - skin involvement (skin papules, erythema nodosum, lupus pernio)
  - peripheral lymphadenopathy
  - arthralgia
  - hepatomegaly ± splenomegaly
- less common extra-pulmonary manifestations involve bone, CNS, kidney
- two acute sarcoid syndromes
  - Lofgren’s syndrome: fever, erythema nodosum, bilateral hilar lymphadenopathy, arthralgias
  - Heerfordt-Waldenstrom syndrome: fever, parotid enlargement, anterior uveitis, facial nerve palsy

Investigations
- CBC (cytopenias from spleen or marrow involvement)
- serum electrolytes, creatinine, liver enzymes, calcium (hypercalcemia/hypercalciuria due to vitamin D activation by granulomas)
- hypergammaglobulinemia, occasionally RF positive
- elevated serum ACE (non-specific and non-sensitive)
- CXR: predominantly nodular opacities especially in upper lung zones ± hilar adenopathy
- PFTs: normal, obstructive pattern, restrictive pattern with normal flow rates and decreased DLCO, or mixed obstructive/restrictive pattern
- ECG: to rule out conduction abnormalities
- slit-lamp eye exam: to rule out uveitis

Diagnosis
- biopsy
  - transbronchial lung biopsy
  - transbronchial lymph node aspiration, endobronchial ultrasound guided surgical (EBUS) biopsy, or mediastinoscopic lymph node biopsy for granulomas
- in ~75% of cases, transbronchial biopsy shows granulomas in the parenchyma even if the CXR is normal

Staging
- radiographic, based on CXR
  - Stage 0: normal radiograph
  - Stage I: bilateral hilar lymphadenopathy ± paratracheal lymphadenopathy
  - Stage II: bilateral hilar lymphadenopathy with pulmonary infiltration
  - Stage III: pulmonary infiltration alone (reticulonodular pattern or nodular pattern)
  - Stage IV: pulmonary fibrosis (honeycombing)

Treatment
- 85% of stage I resolve spontaneously
- 50% of stage II resolve spontaneously
- steroids for symptoms, declining lung function, hypercalcemia, or involvement of eye, CNS, kidney, or heart (not for abnormal CXR alone)
- methotrexate or other immunosuppressives occasionally used

Prognosis
- approximately 10% mortality secondary to progressive fibrosis of lung parenchyma

Known Etiologic Agents

HYPERSENSITIVITY PNEUMONITIS
- also known as extrinsic allergic alveolitis
- non-IgE mediated inflammation of lung parenchyma (acute, subacute, and chronic forms) Type 4 hypersensitivity reaction (see Rheumatology, RH2)
- caused by sensitization to inhaled agents, usually organic dust
- pathology: airway-centred, poorly formed granulomas and lymphocytic inflammation
- exposure usually related to occupation or hobby
  - Farmer’s Lung (Thermophilic actinomycetes)
  - Bird Breeder’s/Bird fancier’s Lung (immune response to bird IgA)
  - Humidifier Lung (Aureobasidium pullulans)
  - Sauna Taker’s Lung (Aureobasidium spp.)

Signs and Symptoms
- acute presentation: (4-6 h after exposure)
  - dyspnea, cough, fever, chills, malaise (lasting 18-24 h)
  - CXR: diffuse infiltrates
  - type III (immune complex) reaction
• subacute presentation: more insidious onset than acute presentation
• chronic presentation
  • insidious onset
  • dyspnea, cough, malaise, anorexia, weight loss
  • PFTs: progressively restrictive
  • CXR: predominantly upper lobe reticulonodular pattern
• in both acute and chronic reactions, serum precipitins may be detectable (neither sensitive nor specific)

Treatment
• early diagnosis: avoidance of further exposure is critical as chronic changes are irreversible
• systemic corticosteroids can relieve symptoms and speed resolution

PNEUMOCONIOSES
• reaction to inhaled inorganic dusts 0.5-5 µm in size
• no effective treatment, therefore key is exposure prevention through the use of protective equipment
• smoking cessation, annual influenza and pneumococcal vaccination rehabilitation, lung transplant for endstage disease

Table 18 Pneumoconioses

<table>
<thead>
<tr>
<th>Diagnosis</th>
<th>Etiology</th>
<th>Signs/Symptoms</th>
<th>Investigations</th>
<th>Complications</th>

</thead>
<tbody>
<tr>
<td>Asbestosis</td>
<td>Exposure risks: insulation, shipyard, construction, brake linings, pipe fitters plumbers Slightly progressive diffuse interstitial fibrosis induced by inhaled asbestos fibres Usually requires &gt;10-20 yr of exposure Latency period: 20-30 yr</td>
<td>Insidious onset Dyspnea Cough: paroxysmal, non-productive Clubbing (much more likely in asbestosis than silicosis or CWP)</td>
<td>CXR Lower &gt; upper lobe Reticulonodular pattern, may develop IPF-like honeycombing Asbestos exposure can also cause pleural and diaphragmatic plaques (calcification), pleural effusion, round atelectasis Microscopic examination reveals ferruginous bodies: yellow-brown rod-shaped structures which represent asbestos fibres coated in macrophages</td>
<td>Asbestos exposure increases risk of bronchogenic CA and malignant mesothelioma Risk of lung cancer dramatically increased for smokers</td>
</tr>
<tr>
<td>Silicosis</td>
<td>At risk population: sandblasters, rock miners, stone cutters, quarry and highway workers Generally requires &gt;20 yr exposure; may develop with much shorter but heavier exposure</td>
<td>Dyspnea, cough, and wheezing</td>
<td>CXR Upper &gt; lower lobe Early: nodular disease (simple pneumoconiosis), lung function usually normal Late: nodules coalesce into masses (progressive massive fibrosis) Possible hilar lymph node enlargement (frequently calcified), especially “egg shell” calcification</td>
<td>Mycobacterial infection (e.g. TB)</td>
</tr>
<tr>
<td>Coal Worker’s Pneumoconiosis (CWP)</td>
<td>At risk population: coal workers, graphite workers Coal and silica, coal is less fibrogenic than silica</td>
<td>Simple CWP No signs or symptoms, usually normal lung function Complicated CWP (also known as progressive massive fibrosis) Dyspnea Course: few patients progress to complicated CWP</td>
<td>Simple CWP CXR: multiple nodular opacities, mostly upper lobe Pathologic hallmark is coal macule Complicated CWP CXR: opacities larger and coalesce</td>
<td>Caplan’s syndrome: rheumatoid arthritis and CWP present as larger nodules</td>
</tr>
</tbody>
</table>

INTERSTITIAL LUNG DISEASE ASSOCIATED WITH DRUGS OR TREATMENTS

Drug-Induced
• antineoplastic agents: bleomycin, mitomycin, busulfan, cyclophosphamide, methotrexate, chlorambucil, BCNU (carmustine)
• antibiotics: nitrofurantoin, penicillin, sulfonamide
• cardiovascular drugs: amiodarone, tocainide
• anti-inflammatory agents: methotrexate, penicillamine
• gold salts
• illicit drugs (heroin, methadone)
• rituximab, anti-TNF-α agents (infliximab, etanercept, adalimumab)

Radiation-Induced
• early pneumonitis: approximately 6 wk post-exposure
• late fibrosis: 6-12 mo post-exposure
• infiltrates conform to the shape of the radiation field
Pulmonary Vascular Disease

Pulmonary Hypertension

Definition
mean pulmonary arterial pressure >25 mmHg at rest and >30 mmHg with exercise, or a systolic pulmonary artery pressure of >40 mmHg at rest

- in the past, pulmonary HTN was classified as primary or secondary pulmonary HTN, but this classification was modified to a more clinically useful, treatment based classification

</tbody>
</table>

IDIOPATHIC PULMONARY ARTERIAL HYPERTENSION (PRIMARY PULMONARY HYPERTENSION)

Definition
- pulmonary HTN in the absence of a demonstrable cause
- histology includes medial hypertrophy, intimal fibrosis and plexiform arteriopathy

- exclude:
  - left-sided cardiac valvular disease
  - myocardial disease
  - congenital heart disease
  - any clinically significant parenchymal lung disease
  - systemic connective-tissue disease
  - chronic thromboembolic disease

Epidemiology
- usually presents in young females (20–40 yr); mean age of diagnosis is 36 yr
- most cases are sporadic; familial predisposition in 10% of cases, some linked to mutations in BMPR2
- may be associated with the use of anorexic drugs (e.g. Aminorex®, Fenfluramine®), amphetamines, and cocaine
**Signs and Symptoms**

<table>
<thead>
<tr>
<th>Table 20. Signs and Symptoms of Pulmonary Hypertension</th>

</tr>
<tr>
<td>Fatigue</td>
</tr>
<tr>
<td>Retrosternal chest pain</td>
</tr>
<tr>
<td>Syncope</td>
</tr>
<tr>
<td>Symptoms of underlying disease</td>
</tr>
</tbody>
</table>

**Investigations**

- CXR: enlarged central pulmonary arteries, cardiac changes due to RV enlargement (filling of retrosternal air space)
- ECG
- RVH/right-sided strain (see Cardiology and Cardiac Surgery, C7)
- 2-D echo doppler assessment of right ventricular systolic pressure
- cardiac catheterization: direct measurement of pulmonary artery pressures (necessary to confirm diagnosis)
- PFTs to assess for underlying lung disease: DLco usually reduced; volumes and flows normal
- CT angiogram to assess lung parenchyma and possible PE
- V/Q scan ± pulmonary angiogram to rule out thromboembolic disease
- serology: ANA positive in 30% of patients with primary pulmonary HTN; other serologic markers can be used in the appropriate clinical setting

**Treatment**

- see Table 19

**Prognosis**

- 2-3 yr mean survival from time of diagnosis
- survival decreases to approximately 1 yr if severe pulmonary HTN or right-heart failure

**Pulmonary Embolism**

**Definition**

- lodging of a blood clot in the pulmonary arterial tree with subsequent increase in pulmonary vascular resistance, impaired V/Q matching, and possibly reduced pulmonary blood flow

**Etiology and Pathophysiology**

- one of the most common causes of preventable death in the hospital
- proximal leg thrombi (popliteal, femoral, or iliac veins) are the source of most clinically recognized pulmonary emboli
- thrombi often start in calf, but must propagate into proximal veins to create a sufficiently large thrombus for a clinically significant PE
- fewer than 30% of patients have clinical evidence of DVT (e.g. leg swelling, pain, or tenderness)
- always suspect PE if patient develops fever, sudden dyspnea, chest pain, or collapse 1-2 wk after surgery

**Risk Factors**

- stasis
- immobilization: paralysis, stroke, bed rest, prolonged sitting during travel, immobilization of an extremity after fracture
- obesity, CHF
- chronic venous insufficiency
- endothelial cell damage
- post-operative injury, trauma
- hypercoagulable states
- underlying malignancy (particularly adenocarcinoma)
- cancer treatment (chemotherapy, hormonal)
- exogenous estrogen administration (OCP, HRT)
- pregnancy, post-pregnancy
- prior history of DVT/PE, family history
- nephrotic syndrome
- coagulopathies: Factor V Leiden, Prothrombin 20210A variant, inherited deficiencies of antithrombin/protein C/protein S, antiphospholipid antibody, hyperhomocysteinemia, increased Factor VIII levels, and myeloproliferative disease
- increasing age

Pulmonary arterial pressures are measured by pulmonary artery catheters (i.e. Swan-Ganz catheter) which are inserted into a large vein (often internal jugular). A balloon at the end of the catheter tip is inflated causing the catheter to advance through the right side of the heart and into the pulmonary artery. This allows for the measurement of RA, RV, PA, and pulmonary capillary wedge pressures as well as sampling of mixed venous blood. A thermistor near the end of the catheter also allows for assessment of cardiac output by thermodilution

Virchow’s Triad

- Venous stasis
- Endothelial cell damage
- Hypercoagulable states

Multidetector Computed Tomography for Acute Pulmonary Embolism (PROPED II Trial)

**Study**

Multicentre, prospective study investigating accuracy of computed tomography angiography (CTA) alone and combined with venous phase imaging (CTA-CTV) for the diagnosis of PE.

**Patients**

324 patients of several thousand eligible for study received reference diagnosis to confirm absence or presence of PE (V/Q scan, venous compression US of lower extremities, and pulmonary digital-subtraction angiography (DSA) if necessary). To confirm absence, patients in whom PE was excluded were telephoned 3-6 mo after enrollment. Any deaths were reviewed by an outcome committee. All patients enrolled also underwent clinical assessment of PE (including a Wells’ score) prior to imaging.

**Outcomes**

Diagnosis of pulmonary embolism.

**Results**

733 of 824 patients had adequate CTA for interpretation. PE was diagnosed in 182 of the 824 patients. Sensitivity was 83% (150 of 181 patients) with 95% CI 0.76-0.91 and specificity was 96% (567 of 592 patients, 95% CI 0.93-0.97). However, the predictive value of CTA-CTV varied when clinical pre-test probability was taken into account. PPV of CTA for high, intermediate, and low clinical probability were 96% (95% CI 0.78-0.99), 92% (95% CI 0.84-0.96), and 58% (95% CI 0.40-0.73), respectively. NPV of CTA for high, intermediate, and low clinical probability were 96% (95% CI 0.82-0.93), and 96% (95% CI 0.92-0.99) respectively.

**Conclusion**

CTA is effective for diagnosing or excluding PE in accordance with assessment of clinical pre-test probability. When clinical probability is inconsistent with imaging results, further investigations are required to rule out PE.
 Investigations (if highly suspicious, go straight to CT angiogram)
- see Emergency Medicine, ER33

</tbody>
</table>

Treatment
- admit for observation (stable patients with DVT only may be sent home on LMWH) |
- oxygen: supplemental O₂ if hypoxic or short of breath |
- pain relief: analgesics if chest pain – narcotics or acetaminophen |
- acute anticoagulation: therapeutic-dose SC LMWH or rivaroxaban or IV heparin (only if concern for bleeding risk) – start ASAP |
- anticoagulation stops clot propagation, prevents new clots and allows endogenous fibrinolytic system to dissolve existing thromboemboli over months get baseline CBC, INR, aPTT ± renal function ± liver function |
- for SC LMWH: dalteparin 200 U/kg once daily, enoxaparin 1 mg/kg bid or 1.5mg/kg once daily, or tinzaparin 175 U/kg once daily – no lab monitoring – avoid or reduce dose in renal dysfunction |
- for IV heparin: bolus of 75 U/kg (usually 5,000 U) followed by infusion starting at 20 U/kg/h – aim for aPTT 2-3x control |
- rivaroxaban is accepted alternative for acute PE

D-Dimer is elevated in patients with recent surgery, cancer, infection, inflammation, and severe renal dysfunction. It has good sensitivity and negative predictive value, but poor specificity and positive predictive value.

Classic ECG finding of PE is S1-Q3-T3 (inverted T3), but most commonly see only sinus tachycardia.

JAMA 2006

PE Rule Out Criteria (PERC)
Prospective Multicentre Evaluation of the Pulmonary Embolism Rule Out Criteria

J Thromb Hemost 2009;83:416-420

Notes
- Use D-Dim is only if low clinical probability, otherwise use PE rule out criteria and get CT
- Positive V/Q scan rules out the diagnosis
- High probability V/Q scan rules only in the diagnosis if high clinical suspicion
- Inconclusive V/Q scan requires leg US to look for DVT or CT
• long-term anticoagulation
  ■ warfarin: start the same day as LMWH/heparin – overlap warfarin with LMWH/heparin for at least 5 d and until INR in target range of 2-3 for at least 2 d
  ■ LMWH instead of warfarin for pregnancy, active cancer, or high bleeding risk patients
  ■ direct thrombin inhibitors: can treat from outset with rivaroxaban; dabigatran has been shown to have lower bleeding risk than warfarin; no monitoring required, however agents not reversible, so avoid if bleeding concerns

• IV thrombolytic therapy
  ■ if patient has massive PE (hypotension or clinical right heart failure) and no contraindications
  ■ hastens resolution of PE but may not improve survival or long-term outcome and doubles risk of major bleeding

  • interventional thrombolytic therapy
    ■ massive PE may be treated with catheter-directed thrombolysis by an interventional radiologist
    ■ catheter-directed thrombolysis is not recommended over systemic thrombolysis
    ■ IVC filter: only if recent proximal DVT + absolute contraindication to anticoagulation
    ■ duration of long-term anticoagulation: individualized, however generally
      ■ if reversible cause for PE (surgery, injury, pregnancy, etc.): 3-6 mo
      ■ if PE unprovoked: 6 mo to indefinite
      ■ if ongoing major risk factor (active cancer, antiphospholipid antibody, etc.): indefinite

Thromboprophylaxis
• mandatory for most hospital patients: reduces DVT, PE, all-cause mortality, cost-effective
• start ASAP
• continue at least until discharge or recommend extending for 35 d post-operatively, if major orthopedic surgery

Thrombophilia Workup: recurrent or idiopathic DVT/PE, age <50, Fx, unusual location, massive
Malignancy Workup: 12% of patients with idiopathic VTE will have a malignancy

The Use of Unfractionated Heparin Should Be Limited to:
• Patients with severe renal dysfunction (CrCl <30 ml/min) n whom LMWH and novel oral anticoagulation should be avoided
• Patients at elevated risk of bleeding that may need rapid reversal of anticoagulation
• Patients who receive thrombolytic therapy

Extended Use of Dabigatran, Warfarin or Placebo in Venous Thromboembolism
NEJM 2013;368:709-718
Study: Two double-blind, RCTs; one comparing against placebo, the other against active treatment.
Population: 4,199 patients (2,896 in active-control study, 1,343 in placebo-control study) with VTE who had completed at least 3 mo of therapy. Intervention: In the active-control study, patients randomized to either 150 mg dabigatran or warfarin (INR 2.5-3.0). Patients in the placebo-control study received either 100 mg dabigatran or placebo.
Outcome: Reocurrence of VTE, risk of major or clinically relevant bleed.
Results: In the active-control study, there was a hazard ratio (HR) of 1.44 (95% CI 0.78-2.64) for non-inferiority of recurrent VTE with dabigatran vs. warfarin. HR of major or clinically relevant bleed was 0.94 (95% CI 0.41-1.71). In the placebo-control study, the HR of VTE with dabigatran vs. placebo was 0.59 (96% CI 0.02-2.58). HR of major or clinically relevant bleed was 2.92 (95% CI 1.35-6.36).
Conclusions: Dabigatran appears to be non-inferior to warfarin in the prevention of VTE recurrence. Dabigatran is associated with a lower risk of major or clinically relevant bleed than warfarin, but greater than placebo.

Diseases of the Mediastinum and Pleura

Mediastinal Masses

Definition
- mediastinum: bound by the thoracic inlet, diaphragm sternum, vertebral bodies, and the pleura
- can be broken down into 3 compartments: anterior, middle, and posterior

Etiology and Pathophysiology
- diagnosis is aided by location and patient’s age
- anterior compartment: more likely to be malignant
  - “Four Ts” (see sidebar), lymphoma, lipoma, pericardial cyst
- middle compartment
  - pericardial cyst, bronchogenic cyst/tumour, lymphoma, lymph node enlargement, aortic aneurysm
- posterior compartment
  - neurogenic tumours, meningocele, enteric cysts, lymphoma, diaphragmatic hernias, esophageal tumour, aortic aneurysm

Signs and Symptoms
- 50% asymptomatic (mainly benign); when symptomatic, 50% are malignant
- chest pain, cough, dyspnea, recurrent respiratory infections
- hoarseness, dysphagia, Horner’s syndrome, facial/upper extremity edema (SVC compression)
- paraneoplastic syndromes (e.g. myasthenia gravis [thymomas])

Investigations
- CXR (compare to previous)
- CT with contrast (anatomic location, density, relation to mediastinal vascular structures)
- MRI: specifically indicated in the evaluation of neurogenic tumours
- U/S (best for assessment of structures in close proximity to the heart and pericardium)
- radionuclide scanning: 131I (for thyroid), gallium (for lymphoma)
- biochemical studies: thyroid function, serum calcium, phosphate, PTH, AFP, β hCG
- biopsy (mediastinoscopy, percutaneous needle aspiration)

Management
- excision if symptomatic enlarging benign masses or concerns of malignancy
- resect bronchogenic cysts and localized neurogenic tumours via minimally invasive video assisted procedures
- exploration via sternotomy or thoracotomy
- diagnostic biopsy rather than major operation if mass is likely to be a lymphoma, germ cell tumour, or unresectable invasive malignancy
- ± post operative radiotherapy/chemotherapy if malignant
Mediastinitis

- most common causes: post-operative complications of cardiovascular or thoracic surgical procedures

**Acute**
- etiology
  - complication of endoscopy (e.g. esophageal perforation providing entry point for infection)
  - esophageal or cardiac surgery
  - tumour necrosis
- signs and symptoms
  - fever, substernal pain
  - pneumomediastinum, mediastinal compression
  - Hamman’s sign (auscultatory “crunch” during cardiac systole)
- treatment
  - antibiotics (IV vancomycin + 3rd gen cephalosporin), drainage, ± surgical closure of perforation

**Chronic**
- usually granulomatous process or fibrosis related to previous infection (e.g. histoplasmosis, TB, sarcoidosis, syphilis)

Pleural Effusions

**Definition**
- excess amount of fluid in the pleural space (normally up to 25 mL)

**Etiology**
- disruption of normal equilibrium between pleural fluid formation/entry and/or pleural fluid absorption/exit
- pleural effusions are classified as transudative or exudative
  - distinguish clinically using Light’s Criteria, which has a sensitivity of 98% and specificity of 83% for identifying exudative pleural effusions

<table>
<thead>
<tr>

<td>LDH – Pleural/Serum</td>
<td>&gt;0.6</td>
</tr>
<tr>
<td>Pleural LDH</td>
<td>&gt;2/3 upper limit of N serum LDH</td>
</tr>
</tbody>
</table>

**Transudative Pleural Effusions**
- pathophysiology: alteration of systemic factors that affect the formation and absorption of pleural fluid (e.g. increased capillary hydrostatic pressure, decreased plasma oncotic pressure)
- etiology
  - CHF: usually right-sided or bilateral
  - cirrhosis leading to hepatic hydrothorax
  - nephrotic syndrome, protein losing enteropathy, cirrhosis
  - pulmonary embolism (may cause transudative but more often causes exudative effusion)
  - peritoneal dialysis, hypothyroidism, CF, urinothorax

**Exudative Pleural Effusions**
- pathophysiology: increased permeability of pleural capillaries or lymphatic dysfunction
- etiology (see Table 25)
Table 25. Exudative Pleural Effusion Etiologies

</tbody>
</table>

**Signs and Symptoms**
- often asymptomatic
- dyspnea: varies with size of effusion and underlying lung function
- orthopnea
- pleuritic chest pain
- inspection: trachea deviates away from effusion, ipsilateral decreased expansion
- percussion: decreased tactile fremitus, dullness
- auscultation: decreased breath sounds, bronchial breathing and egophony at above fluid level, pleural friction rub

**Investigations**
- **CXR**
  - must have >200 mL of pleural fluid for visualization on PA film
  - lateral: >50 mL leads to blunting of posterior costophrenic angle
  - PA: blunting of lateral costophrenic angle
  - dense opacification of lung fields with concave meniscus
  - decubitus: fluid will layer out unless it is loculated
  - supine: fluid will appear as general haziness
- CT may be helpful in differentiating parenchymal from pleural abnormalities, may identify underlying lung pathology
- U/S: detects small effusions and can guide thoracentesis
- thoracentesis: indicated if pleural effusion is a new finding; be sure to send off blood work (LDH, glucose, protein) at the same time for comparison
  - risk of re-expansion pulmonary edema if >1.5 L of fluid is removed
  - inspect for colour, character, and odour of fluid
  - analyze fluid
- pleural biopsy: indicated if suspect TB, mesothelioma, or other malignancy (and if cytology negative)

**Appearance of Pleural Fluid**
- Bloody: trauma, malignancy
- White: empyema, chylous or chyliform effusion
- Black: aspergillosis, amoebic liver abscess
- Yellow-green: rheumatoid pleurisy
- Viscous: malignant mesothelioma
- Ammonia odour: urinotherax
- Food particles: esophageal rupture

**Role of CT in Pleural Effusion**
- To assess for fluid loculation, pleural thickening and nodules, parenchymal abnormalities and adenopathy
- Helps to distinguish benign from malignant effusion and transudative from exudative effusion
- May not distinguish empyema from parapneumonic effusion

**Features of Malignant Effusion**
- Multiple pleural nodules

**Features of Exudative Effusion**
- Loculation
- Pleural thickening
- Pleural nodules
- Extrapleural fat of increased density

</tbody>
</table>

Treatment
- thoracentesis
- treat underlying cause
- consider indwelling pleural catheter or pleurodesis in refractory effusions

Complicated Effusion
- persistent bacteria in the pleural space but fluid is non-purulent
- neutrophils, pleural fluid acidosis (pH < 7.00), and high LDH
- often no bacteria grown since rapidly cleared from pleural space
- fibrin layer leading to loculation of pleural fluid
- treatment: antibiotics depending on gram stain and chest tube drainage

Empyema

Definition
- pus in pleural space or an effusion with organisms seen on a Gram stain or culture (e.g. pleural fluid is grossly purulent)
- positive culture is not required for diagnosis

Etiology
- contiguous spread from lung infection (most commonly anaerobes) or infection through chest wall (e.g. trauma, surgery)

Signs and Symptoms
- fever, pleuritic chest pain

Investigations
- CT chest
- thoracentesis
- PMNs (lymphocytes in TB) ± visible organisms on Gram stain

Treatment
- antibiotic therapy for at least 4-6 wk (rarely effective alone)
- complete pleural drainage with chest tube
- if loculated, more difficult to drain – may require surgical drainage with video-assisted thorascopic surgery (VATS), or removal of fibrin coating (surgical or tPA/DNase) to allow lung re-expansion (decortication)

Atelectasis

- see General Surgery, GS10
**Pneumothorax**

**Definition**
- presence of air in the pleural space

**Pathophysiology**
- entry of air into pleural space raises intrapleural pressure causing partial lung deflation

**Etiology**
- traumatic: penetrating or non-penetrating chest injuries
- iatrogenic (central venous catheter, thoracentesis, mechanical ventilation with barotrauma)
- spontaneous (no history of trauma)
  - primary (no underlying lung disease)
    - spontaneous rupture of apical subpleural bleb (packets of air) of lung into pleural space
  - secondary (underlying lung disease)
    - rupture of subpleural bleb which migrates along bronchioalveolar sheath to the mediastinum then to the intrapleural space
    - necrosis of lung tissue adjacent to pleural surface
  - smoking, male, family history, Marfan’s syndrome

**Signs and Symptoms**
- can be asymptomatic
- acute-onset pleuritic chest pain, dyspnea
- tachypnea, tachycardia
- tracheal deviation (contralateral deviation in tension pneumothorax)
- ipsilateral diminished chest expansion
- decreased tactile/vocal fremitus
- hyperresonance
- ipsilateral diminished breath sounds

**Investigations**
- **CXR**
  - small: separation of visceral and parietal pleura seen as fine crescentic line parallel to chest wall at apex
  - large: decreased density and decreased volume of lung on side of pneumothorax
  - see Medical Imaging, MI8

**Treatment**
- primary spontaneous pneumothorax
  - stable, small (<3 cm), minimal symptoms: observation + O₂
  - if symptomatic or large (>3 cm): aspiration
  - unstable/tension pneumothorax: needle decompression then chest tube, and VATS if unsuccessful (25-50%)
- secondary spontaneous pneumothorax
  - stable, small (<3 cm), minimal symptoms: observation + O₂
  - if symptomatic, large, or unstable: chest tube, and VATS if unsuccessful

**Asbestos-Related Pleural Disease and Mesothelioma**

**Etiology and Pathophysiology**
- benign manifestations of asbestos exposure:
  - “benign asbestos pleural effusion”
    - exudative effusion, typically ~10 yr after exposure, resolves
    - pleural plaques, usually calcified
      - marker of exposure; usually an asymptomatic radiologic finding
  - mesothelioma
    - primary malignancy of the pleura
    - decades after asbestos exposure (even with limited exposure)
    - smoking not a risk factor, but asbestos and smoking synergistically increase risk of lung cancer

**Signs and Symptoms**
- persistent chest pain, dyspnea, cough, bloody pleural effusion, weight loss

**Investigations**
- biops (pleuroscopic or open)
- needle biopsy may seed needle tract with tumour

**Treatment**
- resection (extrapleural pneumonectomy) requires careful patient selection; rarely successful (average survival <1 yr)
Respiratory Failure

**Definition**
- failure of respiratory system to maintain normal blood gases
- hypoxemic (PaO₂ <60 mmHg)
- hypercapnic (PaCO₂ >50 mmHg)
- acute vs. chronic (compensatory mechanisms activated)

**Signs and Symptoms**
- signs of underlying disease
- hypoxemia: restlessness, confusion, cyanosis, coma, cor pulmonale
- hypercapnia: headache, dyspnea, drowsiness, asterixis, warm periphery, plethora, increased ICP (secondary to vasodilatation)

**Investigations**
- serial ABGs
- CXR and/or CT, bronchoscopy to characterize underlying cause if unclear

---

**Hypoxemic Respiratory Failure**

**Definition**
- PaO₂ decreased, PaCO₂ normal or decreased

**Treatment**
- reverse the underlying pathology
- oxygen therapy: maintain oxygenation (if shunt present, supplemental O₂ is less effective; see Anesthesia and Perioperative Medicine, A10, for oxygen delivery systems)
- ventilation, BiPAP, and PEEP/CPAP (see Anesthesia and Perioperative Medicine, A10): positive pressure can recruit alveoli and redistribute lung fluid
- improve cardiac output: ± hemodynamic support (fluids, vasopressors, inotropes), reduction of O₂ requirements

---

**Hypercapnic Respiratory Failure**

**Definition**
- PaCO₂ increased, PaO₂ decreased

**Pathophysiology**
- increased CO₂ production: fever, sepsis, seizure, acidosis, carbohydrate load
- alveolar hypoventilation: COPD, asthma, CF, chest wall disorder, dead space ventilation (rapid shallow breathing)
  - inefficient gas exchange results in inadequate CO₂ removal in spite of normal or increased minute volume
- hypoventilation
  - central: brainstem stroke, hypothyroidism, severe metabolic alkalosis, drugs (opiates, benzodiazepines)
  - neuromuscular: myasthenia gravis, Guillain-Barré, phrenic nerve injury, muscular dystrophy, polymyositis, kyphoscoliosis
  - muscle fatigue

**Dead Space**
- Ventilation without perfusion
- The opposite of shunt

**Causes of Hypercapnia**
- High Inspired CO₂
- ow Total Ventilation
- High Deadspace Ventilation
- High CO₂ Production
Acute Respiratory Distress Syndrome

Definition
- Clinical syndrome characterized by severe respiratory distress, hypoxemia, and noncardiogenic pulmonary edema
- The Berlin Criteria (JAMA 2012; 307:2526-2533) for ARDS
  - Acute onset
    - Within 7 d of a defined event, such as sepsis, pneumonia, or patient noticing worsening of respiratory symptoms
    - Usually occurs within 72 h of presumed trigger
  - Bilateral opacities consistent with pulmonary edema on either CT or CXR
  - Not fully explained by cardiac failure/fluid overload, but patient may have concurrent heart failure
  - Objective assessment of cardiac function (e.g. echocardiogram) should be performed even if no clear risk factors

Etiology
- Direct lung injury
- Airway: aspiration (gastric contents, drowning), pneumonia, inhalation injury (oxygen toxicity, nitrogen dioxide, smoke)
- Circulation: embolism (fat, amniotic fluid), reperfusion injury
- Indirect lung injury
- Circulation: sepsis, shock, trauma, blood transfusion, pancreatitis
- Neurogenic: head trauma, intracranial hemorrhage, drug overdose (narcotics, sedatives, TCAs)

Pathophysiology
- Disruption of alveolar capillary membranes → leaky capillaries → interstitial and alveolar pulmonary edema → reduced compliance, V/Q mismatch, shunt, hypoxemia, pulmonary HTN

Clinical Course
A. Exudative Phase
- First 7 d of illness after exposure to ARDS precipitant
- Alveolar capillary endothelial cells and type I pneumocytes are injured, resulting in loss of normally tight alveolar barrier
- Patients develop dyspnea, tachypnea, increased work of breathing
  - These result in respiratory fatigue and eventually respiratory failure (see Hypoxic Respiratory Failure, R26)

B. Fibroproliferative Phase
- After day 7
- May still experience dyspnea, tachypnea, fatigue, and hypoxemia
- Most patients clinically improve and are able to wean off mechanical ventilation
- Some patients develop fibrotic lung changes that may require long term support on supplemental oxygen or even mechanical ventilation
- If fibrosis present, associated with increased mortality

Treatment
- Based on ARDS Network (see Landmark Respiratory Trials, R38)
- Treat underlying disorder (e.g. antibiotics if infection present)
- Mechanical ventilation using low tidal volumes (<6 mL/kg) to prevent barotrauma
  - Use optimal amount of PEEP (positive end-expiratory pressure) to keep airways open and allow the use of lower FiO2
  - May consider using prone ventilation, ± inhaled nitric oxide, short term paralytics (<48 h) or ECMO (extracorporeal membrane oxygenation) if conventional treatment is failing
- Fluids and inotropic therapy (e.g. dopamine, vasopressin) if cardiac output inadequate
- Pulmonary-arterial catheter now seldom used for monitoring hemodynamics
- Mortality: 30–40%, usually due to non-pulmonary complications
- Sequelae of ARDS include residual pulmonary impairment, severe debilitation, polyneuropathy and psychologic difficulties, which gradually improve over time
- Most survivors eventually regain near-normal lung function, often with mildly reduced diffusion capacity

*In chronic hypercapnia, supplemental O2 may decrease the hypoxic drive to breathe, but do not deny oxygen if the patient is hypoxic.

In COPD patients with chronic hypercapnia ("CO2 retainers"), provide supplemental oxygen to achieve target SaO2 from 88-92%.

ALI vs. ARDS: Definition is the same, except ALI is a PaO2/FiO2 ≥ 300, while ARDS is a PaO2/FiO2 ≤ 200.

| Categorization of ARDS as Mild, Moderate or Severe – The Berlin Criteria |
|-----------------------------|-----------------------------|
| ARDS Severity   | P.O2/FiO2 (mmHg)* | Mortality (95% CI)# |
| Mild            | 200-300            | 27 (24-30)%        |
| Moderate        | 100-200            | 32 (29-34)%        |
| Severe          | < 100              | 45 (42-48)%        |

*On 5–10 cm H2O PEEP, P<0.001
JAMA 2012; 307:2526-2533

ALI: Acute Lung Injury
ARDS: Acute Respiratory Distress Syndrome
FiO2: Fraction of inspired oxygen
PaO2: Arterial partial pressure of oxygen
PEEP: Positive end-expiratory pressure
PaCO2: Arterial partial pressure of carbon dioxide
SaO2: Arterial oxygen saturation

Neoplasms

Lung Cancer

Classification
- Lung tumours can be classified as primary or secondary, benign or malignant, endobronchial or parenchymal.
- Bronchogenic carcinoma (epithelial lung tumours) are the most common type of primary lung tumour (other types make up less than 1%).
  - Small cell lung cancer (SCLC): 10-15%
  - Non-small-cell lung cancer (NSCLC): 85-90%
    - Squamous cell carcinoma: arise from the proximal respiratory epithelium
    - Adenocarcinoma: incidence is increasing; most common subtype in nonsmokers
      - Mucinous adenocarcinoma: grows along the alveolar wall in the periphery; may arise at sites of previous lung scarring
  - Large cell undifferentiated cancer: diagnosis of exclusion
- Benign epithelial lung tumours can be classified as papillomas or adenomas.

</tbody>
</table>

Risk Factors
- Cigarette smoking: the relative risk of developing lung cancer is 10-30 times higher for smokers than for nonsmokers.
- Risk of lung cancer increases with number of cigarettes smoked per day (linear) and duration of smoking (exponential).
- Other risk factors include cigar smoking, pipe smoking, second-hand smoke, asbestos without smoking (relative risk is 3), asbestos with smoking (relative risk is 92), metals (e.g., chromium, arsenic, nickel), radon gas, ionizing radiation, genetics.

Signs and Symptoms
- May be due to primary lesion, metastasis, or paraneoplastic syndrome.
  - Primary lesion:
    - Cough (75%): beware of chronic cough that changes in character
    - Dyspnea (60%)
    - Chest pain (45%)
    - Hemothysis (35%)
    - Other pain (25%)
    - Clubbing (21%)
    - Constitutional symptoms: anorexia, weight loss, fever, fatigue
  - Metastasis:
    - Lung, hilum, mediastinum, pleura: pleural effusion, atelectasis, wheezing, postobstructive pneumonia
    - Pericardium: pericardial effusion, pericardial tamponade
    - Esophageal compression: dysphagia
    - Phrenic nerve: paralyzed diaphragm
    - Recurrent laryngeal nerve: hoarseness

Summary of Recommendations on Screening for Lung Cancer

Canadian Task Force on Preventative Health Care (2016)
- Screening with CXR (+ sputum cytology) not recommended.
- Screening with low-dose CT recommended for high-risk patients (current or former smokers quit within last 15 yr, aged 55-74, ≥30 pack yr smoking Hx) for 3 consecutive years.
  - Number needed to screen = 322

American College of Chest Physicians (2013)
- Screening with CXR not recommended.
- Screening with low-dose CT recommended for high-risk patients (current or former smokers quit within last 15 yr, aged 55-74, ≥30 pack yr smoking Hx).

American Lung Association (2013)
- Screening with CXR not recommended.
- Screening with low-dose CT recommended for high-risk patients (current or former smokers aged 55-74, ≥30 pack yr smoking Hx, no Hx of lung cancer).

Malignant lung tumours are the most common cause of cancer mortality throughout the world in both men and women.
• superior vena cava syndrome
  • obstruction of SVC causing neck and facial swelling, as well as dyspnea and cough
  • other symptoms: hoarseness, tongue swelling, epistaxis, and hemoptysis
  • physical findings: dilated neck veins, increased number of collateral veins covering the anterior chest wall, cyanosis, edema of the face, arms, and chest, Pemberton’s sign (facial flushing, cyanosis, and distension of neck veins upon raising both arms above head)
  • milder symptoms if obstruction is above the azygos vein

• lung apex (Pancoast tumour): Horner’s syndrome, brachial plexus palsy (most commonly C8 and T1 nerve roots)
• rib and vertebrae: erosion
• distant metastasis to brain, bone, liver, adrenals

• paraneoplastic syndromes
  • a group of disorders associated with malignant disease, not related to the physical effects of the tumour itself
  • most often associated with SCLC

Investigations

• initial diagnosis
  • imaging: CXR, CT chest + upper abdomen, PET scan
  • cytology: sputum
  • biopsy: bronchoscopy, EBUS, CT-guided percutaneous needle biopsy, mediastinoscopy

• staging workup
  • TNM staging system: T – primary tumour (size); N – regional lymph nodes; M – distant metastasis
  • blood work: electrolytes, LFTs, calcium, ALP
  • imaging: CXR, CT thorax and upper abdomen, bone scan, neuroimaging, PET scan
  • invasive: bronchoscopy (EBUS), mediastinoscopy, mediastinotomy, thoracotomy
  • screen adenocarcinoma for EGFR and ALK mutations

Horner has a MAP of the Coast
A Pancoast tumour compresses the cervical sympathetic plexus causing a Horner’s syndrome:
  • Miosis
  • Anhydrosis
  • Ptosis

Reduced Lung Cancer Mortality with Low-Dose CT Screening
NEJM 201;365:395-409
Study: Multicentre, RCT.
Methods: 53,454 participants at high risk for lung cancer (55-74 yr, >30 yr smoking, and smoking cessation for <5 y) were assigned to undergo three annual screenings with either low dose CT or single-view PA CXR.
Results: A relative reduction in mortality from lung cancer with low-dose CT screening of 20.0% (95% CI 6.8-26.7; p=0.004). Rate of death from any cause was reduced in the low-dose CT group as compared to the CXR group by 6.7% (95% CI 1.2-13.6; p=0.02).

<table>
<thead>
<tr>
<th></th>

<td>309/100 K person yr</td>
</tr>
</tbody>
</table>

Conclusions: Screening with low-dose CT reduces mortality from lung cancer.

Endobronchial Ultrasound (EBUS)
• Allows visualization of peri-bronchial structures and distal peripheral lung lesions
• Provides detailed assessment of the airway wall layers
• Allows for guided biopsies of lymph nodes and tumours
• Used for diagnosis and staging

</table>

* Depends on clinical vs. pathologic stage
Refer to AJCC Cancer Staging Manual, 7th ed. 2010 for complete TNM classification

**Treatment**
- options include surgery, radiotherapy, chemotherapy, and palliative care for end-stage disease
- surgery not usually performed for SCLC since it is generally non-curable
- contraindications for surgery
  - spread to contralateral lymph nodes or distant sites
  - patients with potentially resectable disease must undergo mediastinal node sampling since CT thorax is not accurate in 20-40% of cases
  - poor pulmonary status (e.g. unable to tolerate resection of lung)
  - post-op estimated FEV1 and DLCO must be at least 40% of predicted to tolerate surgery
- chemotherapy (used in combination with other treatments)
  - common agents: etoposide, platinum agents (e.g. cisplatinum), ifosfamide, vincristine, anthracyclines, paclitaxel, irinotecan, gefitinib (an endothelial growth factor receptor inhibitor)
  - complications
    - acute: tumour lysis syndrome, infection, bleeding, myelosuppression, hemorrhagic cystitis (cyclophosphamide), cardiotoxicity (doxorubicin), renal toxicity (cisplatin), peripheral neuropathy (vincristine)
    - chronic: neurologic damage, leukemia, additional primary neoplasms

**Approach to the Solitary Pulmonary Nodule**

**Definition**
- a round or oval, sharply circumscribed radiographic lesion up to 3 cm, which may or may not be calcified, and is surrounded by normal lung
- can be benign or malignant

**Table 31. Differential Diagnosis for Benign vs. Malignant Solitary Nodule**

**Hamartomas**
- 10% of benign lung lesions
- Composed of tissues normally present in lung (fat, epithelium, fibrous tissue, and cartilage), but they exhibit disorganized growth
- Peak incidence is age 60, more common in men
- Usually peripheral and clinically silent
- CT shows clustered "popcorn" pattern of calcification (pathognomonic for hamartoma)
**Investigations**
- CXR: always compare with previous CXR
- CT densitometry and contrast enhanced CT of thorax
- sputum cytology: usually poor yield
- biopsy (bronchoscopic or percutaneous) or excision (thoracoscopy or thoracotomy): if clinical and radiographic features do not help distinguish between benign or malignant lesion
  - if at risk for lung cancer, biopsy may be performed regardless of radiographic features
  - if a biopsy is non-diagnostic, whether to observe, re-biopsy, or resect will depend on the level of suspicion
- watchful waiting: repeat CXR and/or CT scan at 3, 6, 12 mo
- PET scan can help distinguish benign from malignant nodules

**Figure 11. Evaluation of a solitary pulmonary nodule**

Sleep-Related Breathing Disorders

Hypoventilation Syndromes

• primary alveolar hypoventilation: idiopathic
• obesity-hypoventilation syndrome (Pickwickian syndrome)
• respiratory neuromuscular disorders

Sleep Apnea

Definition

• episodic decreases in airflow during sleep
• quantitatively measured by the Apnea/Hypopnea Index (AHI) = # of apneic and hypopneic events per hour of sleep
• sleep apnea generally accepted to be present if AHI >15

Classification

• obstructive (OSA)
• caused by transient, episodic obstruction of the upper airway
• absent or reduced airflow despite persistent respiratory effort
  • central (CSA) (see Neurology, N47)
• caused by transient, episodic decreases in CNS drive to breathe
• no airflow because no respiratory effort
• Cheyne-Stokes Respiration: a form of CSA in which central apneas alternate with hyperpneas to produce a crescendo-decrescendo pattern of tidal volume; seen in severe LV dysfunction, brain injury, and other settings (see Figure 2)
• mixed (MSA)
• features of both OSA and CSA
• loss of hypoxic and hypercapnic drives to breathe secondary to "resuscitative breathing": overcompensatory hyperventilation upon awakening from OSA induced hypoxia

Risk Factors

• for OSA: obesity, upper airway abnormality, neuromuscular disease, hypothyroidism, alcohol/sedative use, nasal congestion, sleep deprivation, enlarged tonsils
• for CSA: LV failure, brainstem lesions, encephalitis, encephalopathy, myxedema, high altitude

Signs and Symptoms

• obtain history from spouse/partner
• secondary to repeated arousals and fragmentation of sleep: daytime somnolence, personality and cognitive changes, snoring
• secondary to hypoxemia and hypercapnia: morning headache, polycythemia, pulmonary/systemic HTN, cor pulmonale/CHF, nocturnal angina, arrhythmias
• the typical presentation for OSA is a middle-aged obese male who snores

Investigations

• sleep study (polysomnography)
• evaluates sleep stages, airflow, ribcage movement, ECG, SaO2, limb movements
• indications
  • excessive daytime sleepiness
  • unexplained pulmonary HTN or polycythemia
  • daytime hypercapnia
  • titration of optimal nasal CPAP
• assessment of objective response to other interventions

Treatment

• modifiable factors: weight loss, decreased alcohol/sedatives, nasal decongestion, treatment of underlying medical conditions
• OSA or MSA: nasal CPAP, postural therapy (e.g. no supine sleeping), dental appliance, uvulopalatopharyngoplasty, tonsillectomy
• CSA or hypoventilation syndromes: nasal BiPAP/CPAP, respiratory stimulants (e.g. acetazolamide, theophylline, progesterone) adaptive servoventilation (e.g. progesterone) in select cases
• tracheostomy rarely required and should be used as last resort for OSA

Complications

• depression, weight gain, decreased quality of life, workplace and vehicular accidents, cardiac complications (e.g. HTN), reduced work/social function

Normal Respiratory Changes during Sleep

• Tidal volume decreases
• Arterial CO2 increases (due to decreased minute ventilation)
• Pharyngeal dilator muscles relax causing increased upper airway resistance

Continuous Positive Airways Pressure for Obstructive Sleep Apnea

Cochrane DB Syst Rev 2006;CD001106

Study: Pooled analysis of 36 RCTs (n=1,718) comparing nocturnal CPAP with an inactive control or oral appliances in adults with OSA.

Conclusions: The use of CPAP showed significant improvements in objective and subjective measures including cognitive function, sleepiness, measures of quality of life, and a lower average systolic and diastolic blood pressure. People who responded equally well to CPAP and oral appliances expressed a strong preference for oral appliances; however, participants on oral appliances were more likely to withdraw from therapy.

CPAP has been shown to reduce cardiovascular risk and cardiovascular related deaths in patients with obstructive sleep apnea.
Introduction to Intensive Care

Intensive Care Unit Basics

- goal is to provide stabilization for critically ill patients: hemodynamic, respiratory or cardiac instability, or need for close monitoring

Lines and Catheters

- arterial lines
  - monitor beat-to-beat blood pressure variations, obtain blood for routine ABGs
  - common sites are the radial and femoral arteries
- central venous catheter (central line)
  - administer IV fluids, monitor CVP, insert pulmonary artery catheters
  - administer TPN and agents too irritating for peripheral line (e.g. vasopressors, chemotherapy)
  - common sites: internal jugular vein, subclavian vein, femoral vein
- pulmonary arterial catheter
  - balloon guides the catheter from a major vein to the right heart
  - measures pulmonary capillary wedge pressure (PCWP) via a catheter wedged in distal pulmonary artery
  - PCWP reflects the LA and LV diastolic pressure (barring pulmonary venous or mitral valve disease)
- indications (now used infrequently due to associated complications)
  - diagnosis of shock states, primary pulmonary HTN, valvular disease, intracardiac shunts, cardiac tamponade, PE
  - assessment of hemodynamic response to therapies
  - differentiation of high- versus low-pressure pulmonary edema
  - management of complicated MI, multigang system failure and/or severe burns, or hemodynamic instability after cardiac surgery
  - absolute contraindications
    - tricuspid or pulmonary valve mechanical prosthesis
    - right heart mass (thrombus or tumour)
    - tricuspid or pulmonary valve endocarditis

</tr>
<tr>
<td>Coagulopathy (see Hematology, H53)</td>
<td>Increased INR or PT, Low platelet count, Bleeding, bruising</td>
<td>Treat underlying cause (e.g. thrombocytopenia, drug-related, immune-related, DIC) Transfusion of blood products, clotting factors</td>
</tr>
<tr>
<td>Liver Failure (see Gastroenterology, G35)</td>
<td>Elevated transaminases, Bilirubin, Coagulopathy, Jaundice, Altered mental status (encephalopathy), Hypoglycemia</td>
<td>Treat underlying cause (e.g. viral hepatitis, drug related, metabolic) Lactulose, Liver transplant</td>
</tr>
<tr>
<td>Renal Failure (see Nephrology, NP37)</td>
<td>Elevated creatinine, Reduced urine output, Signs of volume overload (e.g. CHF, effusions)</td>
<td>Treat underlying cause (e.g. shock, drug-related, obstruction) Correct volume and electrolyte status, eliminate toxins Diuretics, Dialysis</td>
</tr>
</tbody>
</table>

Organ Failure
Shock

- see *Emergency Medicine*, ER3
- inadequate tissue perfusion potentially resulting in end organ injury
  - categories of shock
    - hypovolemic: hemorrhage, dehydration, vomiting, diarrhea, interstitial fluid redistribution
    - cardiogenic: myopathic (myocardial ischemia ± infarction), mechanical, arrhythmic pharmacologic
    - obstructive: massive PE (saddle embolus), pericardial tamponade, constrictive pericarditis, increased intrathoracic pressure (e.g. tension pneumothorax)
    - distributive: sepsis, anaphylaxis, neurogenic, endocrine, toxins

### Table 35. Changes Seen in Different Classes of Shock

<td></td>
<td></td>
</tr>
</tbody>
</table>

- treat underlying cause (hypovolemia is the most common cause)
- treatment goal is to return critical organ perfusion to normal (e.g. normalize BP)
- common treatment modalities include
  - fluid resuscitation (NOT in cardiogenic shock)
  - inotropes (e.g. dobutamine), vasopressors (e.g. norepinephrine), vasopressin
  - revascularization or thrombolytics for ischemic events
  - needle decompression or tube thoracostomy for suspected tension pneumothorax

Sepsis

- the leading cause of death in noncoronary ICU settings is multi-organ failure due to sepsis
- the predominant theory is that sepsis is attributable to uncontrollable immune system activation

### Definitions

- the Third International Consensus Definition for Sepsis and Septic Shock (Singer et al. JAMA 2016: 315(8), 801-810) significantly revised sepsis definitions
- sepsis: life threatening organ dysfunction caused by dysregulated host response to infection (see Table 36)
- septic shock: a subset of sepsis, where sufficient circulatory and/or cellular/metabolic abnormalities substantially increase mortality Clinically defined as sepsis with persisting hypotension requiring vasopressors to maintain MAP ≥65 mmHg and having a serum lactate ≥2 mmol/L (18 mg/dL) despite adequate fluid resuscitation

### Signs and Symptoms

- new guidelines recommend the use of quick SOFA (qSOFA) criteria and SOFA score to replace SIRS criteria
- in patients with suspected infection, bedside application of qSOFA criteria identifies individuals with high likelihood of poor outcomes, including prolonged ICU stay and/or death
- a positive qSOFA (≥2 criteria) should prompt application of the SOFA score, and further evaluation of possible infection and organ dysfunction
- in the context of suspected infection, a SOFA score ≥2 reflects an overall mortality risk of 10%
- the absence of ≥2 criteria on either qSOFA or SOFA score should not delay or defer investigation or treatment of infection or any other aspect of care deemed necessary by the practitioners

### Figure 12. Approach to sepsis

Figure adapted from Singer et al: The Third International Consensus Definitions for Sepsis and Septic Shock (Sepsis-3). JAMA 2016; 315(8): 801-810.

#### Treatment

- Identify the cause and source of infection: blood, sputum, urine Gram stain, and C&S
- Initiate empiric antibiotic therapy
- Monitor, restore, and maintain hemodynamic function

#### Surviving Sepsis (adapted from International Guidelines for Management of Severe Sepsis and Septic Shock 2012)

- Adjustments of cardiac preload, afterload, and contractility to balance oxygen delivery with demand
- Initial resuscitation (goals during first 6 h of resuscitation for sepsis induced hypotension persisting after initial fluid challenge or blood lactate ≥ 4 mmol/L)
- Maintain CVP ≥ 12 mmHg with IV crystalloids/colloids
  - Maintain MAP ≥ 65 mmHg with use of vasopressor agents, first line: norepinephrine
  - Urine output ≥ 0.5 mL/kg/hr
  - Central venous (SVC) or mixed oxygen saturation 70% or 65% respectively
- in patients with elevated lactate levels target resuscitation to normalize lactate
- corticosteroid replacement therapy not indicated if adequate hemodynamic stability achieved with fluid resuscitation and vasopressor therapy
- infection control
  - prompt diagnosis of infection
    - cultures as clinically indicated prior to antibiotic therapy if no significant delay
    - imaging studies performed promptly to confirm possible infectious source
  - antibiotic therapy
- administer effective IV antimicrobials within first hour of recognition of sepsis
- choice of anti-infective therapy should consider activity against all likely pathogens and penetration of adequate concentration into tissue presumed to be source of infection
- antimicrobial regimen should be reassessed daily for potential deescalation
- surgical source control when appropriate
- supportive oxygenation and ventilation using lung-protective regimen
- early nutritional support: enteral route is used to preserve function of intestinal mucosal barrier
- DVT/PE prophylaxis
- advanced care planning, including the communication of likely outcome and realistic goals of treatment with patients and families

Anatomy of Joint Pathology

- **Joint swelling**: effusion/synovial thickening
- **Decreased ROM**: range of motion
- **Stress pain (pain at the end of ROM)**
- **Increased warmth**

**Arthralgia**: perception of joint pain without obvious clinical findings

**Active Joint**: swollen joint, joint line tenderness, or stress pain

**Inflammatory Joint**:Joint space narrowing

**Degenerative Joint**: Cartilage destruction, joint space narrowing, osteoarthritis

**Normal Joint**: Normal synovium, joint space, articular cartilage

**Terminology in Rheumatology**

**Arthritis**:
- Joint swelling: effusion/synovial thickening
- Decreased ROM
- Stress pain (pain at the end of ROM)
- Increased warmth

**Articular**: perception of joint pain without obvious clinical findings

**Active Joint**: swollen joint, joint line tenderness, or stress pain

**Innate Immune Cells**

- **Neutrophil (PMN)**: circulate in blood and respond to inflammatory stimuli, kill invading organisms by phagocytosis, degranulation and neutrophil extracellular traps
- **Natural Killer Cell**: innate immunity against intracellular infections (especially viruses), killing function and produce cytokines
- **Macrophage**: active after PMNs, suppress PMN efflux and phagocytosis PMN debris, secrete pro-inflammatory cytokines in response to microbial debris
- **Dendritic Cell**: actively phagocytic when immature, activated by signals from toll-like receptor (TLR) release pro-inflammatory cytokines, present antigens to T cells in lymph nodes
- **Eosinophil**: respond to inflammatory cytokines and degranulate releasing reactive oxygen species, and cytokines, associated with allergy, asthma and parasitic infection
- **Basophils**: present in connective tissue and mucosa, allergen cross-linking of IgE bound to mast cell triggers degranulation and release of inflammatory mediators

**Key Cytokine Targets of Biologic Drugs**

- **TFN**: Source: T cells, macrophages
- **Major Functions**: cachexia, induces other cytokines, T cell stimulation, induces metalloproteases and prosta glandinls, increases expression of adhesion molecules, increases vascular permeability leading to increased entry of IgG, complement and cells into tissues

- **IL-6**: Source: Many cells
- **Major Functions**: proliferation of B and T cells, acute phase reactant, induces natural protease inhibitor

**Immunogenetics and Disease**

- cell surface molecules called HLAs play a role in mediating immune reactions
- MHC a-g genes on the short arm of chromosome 6 that encode HLA molecules
- certain HLA haplotypes are associated with increased susceptibility to autoimmune diseases

Synovial Fluid Analysis

- Synovial fluid is an ultrafiltrate of plasma plus hyaluronic acid; it lubricates joint surfaces and nourishes articular cartilage.

**Indications**
- Diagnostic tests advised if crystal arthritis or hemoarthritis is suspected or if there is unexplained joint, bursa or tendon sheath swelling.
- Therapeutic: drainage of blood, purulent or tense effusions; corticosteroid injection.

**Contraindications**
- Absolute: open lesion or suspected infection of overlying skin or soft tissue.
- Relative: bleeding diathesis, thrombocytopenia, prosthetic joint.

</table>

**Choosing Wisely Canada Recommendations**

1. Do not order ANA as a screening test in patients without specific signs or symptoms of SLE or another CTD.
2. Do not order an HLA-B27 unless spondyloarthritis is suspected based on specific signs or symptoms.
3. Do not repeat DEXA scans more often than every 2 years.
4. Do not prescribe bisphosphonates for patients at low risk of fracture.
5. Do not perform whole body bone scans (e.g. scintigraphy) for diagnostic screening for peripheral and axial arthritis in the adult population.
Septic Arthritis

- Septic arthritis is a medical emergency because it can lead to rapid joint destruction and has a 10-15% risk of mortality.
- Knee and hip are most commonly affected joints.
- Most commonly caused by hematogenous spread of bacterial infection (gram positive cocci > gram negative bacilli).
- Risk factors: very young, portal of entry, recent infection.
- Poor prognostic factors: older age, immunocompromised, delay in treatment, previously damaged joint, joint prosthesis.
- Consider empiric antibiotic therapy until septic arthritis is excluded from history, physical examination and synovial fluid analysis.

- See Infectious Diseases, Gonococcal Arthritis ID14 and Orthopedics, Spetic Joint OR10.

Degenerative Arthritis: Osteoarthritis

- See Family Medicine, FM40

Definition
- Progressive deterioration of articular cartilage and surrounding joint structures caused by genetic, metabolic, biochemical, and biomechanical factors with secondary components of inflammation.

Classification (Based on Etiology)
- Primary (idiopathic)
  - Most common, unknown etiology.
- Secondary
  - Post-traumatic or mechanical
  - Post-inflammatory (e.g. RA) or post-infectious
  - Heritable skeletal disorders (e.g. scoliosis)
  - Endocrine disorders (e.g. acromegaly, hyperparathyroidism, hypothyroidism)
  - Metabolic disorders (e.g. gout, pseudogout, hemochromatosis, Wilson's disease, ochronosis)
  - Neuropathic (e.g. Charcot joints)
    - Atypical joint trauma due to peripheral neuropathy (e.g. diabetes mellitus, syphilis)
  - Avascular necrosis (AVN)
  - Other (e.g. congenital malformation).

Pathophysiology
- The process appears to be initiated by abnormalities in biomechanical forces and/or, less often, in cartilage.
- Elevated production of pro-inflammatory cytokines is important in OA progression.
- Tissue catabolism > repair.
- Contributing factors (mechanisms unknown): genetics, alignment (bow-legged, knock-kneed), joint deformity (hip dysplasia), joint injury (meniscal or ligament tears), obesity, environmental, mechanical loading, age and gender.
- Now considered to be a systemic musculoskeletal disorder rather than a focal disorder of synovial joints.

Epidemiology
- Most common arthropathy (accounts for ~75% of all arthritis).
- Increased prevalence with increasing age (35% of 30 yr olds, 85% of 80 yr olds).

Risk Factors
- Genetic predisposition, advanced age, obesity (for knee and hand OA), female, trauma.

Signs and Symptoms
- Localized to affected joints (not a systemic disease).
- Pain is often insidious, gradually progressive, with intermittent flares and remissions; neuropathic pain may also be present.
- Fatigue, poor sleep, impact on mood (depression, anxiety).

Table 9. Signs and Symptoms of OA

<table>
<thead>
<tr>
<th>Signs</th>
<th>Symptoms</th>
</tr>
</thead>
<tbody>
<tr>
<td>Joint line tenderness; stress pain ± joint effusion</td>
<td>Joint pain with motion; relieved with rest</td>
</tr>
<tr>
<td>Bony enlargement at affected joints</td>
<td>Short duration of stiffness (&lt;1/2 h) after immobility</td>
</tr>
<tr>
<td>Malalignment/deformity (angulation)</td>
<td>Joint instability/buckling</td>
</tr>
<tr>
<td>Limited ROM</td>
<td>Joint locking due to “joint mouse” (bone or cartilage fragment)</td>
</tr>
<tr>
<td>Crepitus on passive ROM</td>
<td>Loss of function or other internal derangements (e.g. meniscal tear)</td>
</tr>
<tr>
<td>Inflammation (mild if present)</td>
<td>Peniarticular muscle atrophy</td>
</tr>
</tbody>
</table>

ESR can also be elevated in anemia, end-stage renal disease, females, increased age, and obesity.

Figure 3. Common sites of joint involvement in OA

1. Thumb squaring
2. Heberden's nodes
3. Bouchard's nodes

Figure 4. Hand findings in OA
Joint Involvement
- generalized osteoarthritis: 3+ joint groups
- asymmetric (knees usually affected bilaterally)
- hand
  - DIP (Heberden’s nodes = osteophytes → enlargement of joints)
  - PIP (Bouchard’s nodes)
  - CMC (usually thumb squaring)
  - 1st MCP (other MCPs are usually spared)
- hip
  - usually presents as groin pain ± dull or sharp pain in the trochanteric area, internal rotation and abduction are lost first
  - pain can radiate to the anterior thigh, but generally does not go below the knee
- knee
  - initial narrowing of one compartment, medial > lateral; seen on standing x-rays, often patellar-femoral joint involved
- foot
  - common in first MTP and midfoot
- lumbar spine
  - very common, especially L4-L5, L5-S1
  - degeneration of intervertebral discs and facet joints
  - reactive bone growth can contribute to neurological impingement (e.g. sciatica, neurogenic claudication) or spondylolisthesis (forward or backward movement of one vertebra over another)
- cervical spine
  - commonly presents with neck pain that radiates to scapula, especially in mid-lower cervical area (C5 and C6)

Investigations
- blood work
  - normal CBC and ESR, CRP
  - negative RF and ANA
- radiology: 4 hallmark findings, see sidebar
- synovial fluid: non-inflammatory (see Table 8)

Treatment
- presently no treatment alters the natural history of OA
- prevention: prevent sports injury, healthy weight management
- non-pharmacological therapy
  - weight loss (minimum 5-10 lb loss) if overweight
  - physiotherapy: heat/cold, low impact exercise programs
  - occupational therapy: aids, splints, cane, walker, bracing
- pharmacological therapy (see Table 33)
  - 1st line- oral: acetaminophen/NSAIDs
  - treat neuropathic pain if present (anti-depressants, anti-epileptics, etc.)
  - joint injections: corticosteroid (effective for short-term treatment), hyaluronic acid (evidence of long-term benefits)
  - topical: capsaicin, NSAIDs
  - glucosamine ± chondroitin (efficacy not well supported)
- surgical treatment
  - joint debridement, osteotomy, total and/or partial joint replacement, fusion (see Orthopedics, OR6)

## Rheumatoid Arthritis

### Definition
- chronic, symmetric, erosive synovitis of peripheral joints (e.g. wrists, MCPs, MTPs)
- characterized by a number of extra-articular features

### Table 12. 2010 ACR/EULAR Classification Criteria for RA

RA is an independent risk factor for atherosclerosis and CV disease. RA is associated with increased overall mortality/morbidity from all causes: CV disease, neoplasm (especially lymphoma), infection

Common Presentation
- Morning stiffness >1 h, improves with use
- Symmetric joint involvement
- Initially involves small joints of hands and feet
- Constitutional symptoms
Pathophysiology
- autoimmune disorder, unknown etiology
- complex interaction of genes and environment leading to breakdown of immune tolerance; many pathways result in autoreactivity leading to a final common pathway to synovial inflammation
  - genetic predisposition: HLA-DR4/DR1 association (93% of patients have either HLA type), cytokine promoters, T cell signaling
  - induction of enzymes that convert arginine to citrulline caused by environmental stress (cigarette smoking)
  - RA: propensity for immune reactivity to neoepitopes created by protein citrullination and production of anti-citrullinated protein antibodies
- once inflammatory process is established, synovium organizes itself into an invasive tissue that degrades cartilage and bone
- progressive bone destruction with absence of bone repair in response to inflammation
  - elevated TNF level increases osteoclasts and decreases osteoblasts at the site of inflammation
  - upregulation of RANK ligand increases osteoclast-mediated destruction

Epidemiology
- most common inflammatory arthritis: prevalent in 1% of population
- F:M = 3:1
- age of onset 20-40 yr

Signs and Symptoms
- variable course of exacerbations and remissions
- morning stiffness >1 h, improves with use, worsens with rest
- polyarthritis: symmetric joint involvement (tender, swollen), small joints affected, most commonly in hands and feet (MCP, PIP, MTP)
- extra-articular (systemic) symptoms: profound fatigue, depression, myalgia, weight loss
- limitation of function and decrease in global functional status
- complications of chronic synovitis
  - signs of mechanical joint damage: loss of motion, instability, deformity, crepitus, joint deformities
    - swan neck deformity boutonnière deformity
    - ulnar deviation of MCP, radial deviation of wrist joint
    - hammer toe, mallet toe, claw toe
    - flexion contractures
    - atlanto-axial and subaxial subluxation
    - C-spine instability
    - neurological impingement (long tract signs)
      difficult/dangerous intubation: risk of worsening subluxation and damage to spinal cord
- limited shoulder mobility, spontaneous tears of the rotator cuff leading to chronic spasm
- tenosynovitis may cause rupture of tendons
- carpal tunnel syndrome
- ruptured Baker’s cyst (outpouching of synovium behind the knee); presentation similar to acute DVT
- poor prognostic factors include: young age of onset, high RF titer, elevated ESR, activity of >20 joints, and presence of extra-articular features

Classification of Global Functional Status in RA
- Class I: able to perform usual ADLs (self-care, vocational, avocational)
- Class II: able to perform self-care and vocational activities, restriction of avocational activities
- Class III: able to perform self-care, restriction of vocational and avocational activities
- Class IV: limited ability to perform self-care, vocational, and avocational activities
Investigations
- blood work
  - RF: 80% sensitivity but non-specific; may not be present at onset of symptoms; levels DO NOT correlate with disease activity
  - can be associated with more erosions, more extra-articular manifestations, and worse function
  - anti-CCP: 80% sensitivity but more specific (94-98%); may precede onset of symptoms
- increased disease activity is associated with decreased Hb (anemia of chronic disease), increased platelets, ESR, CRP, and RF
- imaging
  - x-rays may be normal at onset
  - first change is periarticular osteopenia, followed by erosions
  - U/S (with power doppler) MRI may be used to image hands to detect early synovitis and erosions
    - MRI T1 inflamed synovium is hypointense and hyperintense on T1; bone marrow edema can be seen as well as areas of increased uptake gadolinium contrast

Treatment
- goals of therapy: remission or lowest possible disease activity
  - key is early diagnosis and early intervention with DMARDs
  - “window of opportunity” = early treatment within first 3 mo of disease may allow better control/remission
  - assess poor prognostic factors at baseline (RF positive, functional limitations and extra-articular features)
- behavioural
  - exercise program (isometrics and active, gentle ROM exercise during flares, aquatic/aerobic/strengthening exercise between flares), assistive devices as needed
  - job modification may be necessary
- pharmacologic: alter disease progression
  - only DMARDs and biologics (not analgesics or NSAIDs) can alter the course of RA
  - DMARDs
    - methotrexate (MTX) is the gold standard and is first-line unless contraindicated
      - chest X-ray should be assessed prior to MTX therapy
      - if inadequate response (3-6 mo) → combine or switch
      - consider including add-on medications to MTX if patients have poor prognostic features or high disease activity
      - add-ons include: hydroxychloroquine, sulfasalazine, leflunomide
  - biologics
    - should be combined with DMARD therapy (initiating with combination therapy is associated with faster response rates) or used if inadequate response to DMARDs
    - first-line (anti-TNF) options: infliximab, etanercept, adalimumab, golimumab and certolizumab
    - non-anti-TNF agents include anakinra, abatacept, rituximab and tocilizumab
  - reassess every 3-6 mo and monitor disease severity
- pharmacologic: reduce inflammation and pain
  - NSAIDs
    - individualize according to efficacy and tolerability
    - contraindicated/cautioned in some patients (e.g. PUD, ischemic cardiac disease, pregnancy)
  - add acetaminophen ± opioid prn for synergistic pain control
- corticosteroids
  - local: injections to control symptoms in a specific joint
  - systemic (prenisone)
    - low dose (5-10 mg/d) useful for short-term to improve symptoms if NSAIDs are ineffective to bridge gap until DMARDs take effect
    - severe RA: add low dose prednisone to DMARDs
  - do baseline DEXA bone density scan and consider bone supportive pharmacologic therapy if using corticosteroids >3 mo at 7.5 mg/d
  - cautions/contraindications: active infection, TB, osteoporosis, HTN, gastric ulcer, DM
  - surgical
    - indicated for structural joint damage
- surgical options include: synovectomy, joint replacement, joint fusion, reconstruction/tendon repair

Follow-Up Management and Clinical Outcomes
- follow-up every 3-6 mo, then 6-12 mo after inflammation has been suppressed
- examine joints for active inflammation – if active, consider adjusting medications, PT/OT
- if assessment reveals joint damage – consider analgesia, referral to PT/OT, surgical options
- outcome depends on disease activity, joint damage, physical functional status, psychological health, and comorbidities
- functional capacity is a useful tool for determining therapeutic effectiveness; many tools for evaluation have been validated
- patients with RA have an increased prevalence of other serious illnesses: infection (e.g. pulmonary, skin, joint), renal impairment, lymphoproliferative disorders, cardiovascular disease (correlates with disease activity and duration)
- increased risk of premature mortality, decreased life expectancy (most mortality not directly caused by RA)
Systemic Lupus Erythematosus

- see Nephrology, NP24

Definition
- chronic inflammatory multi-system disease of unknown etiology
- characterized by production of autoantibodies and diverse clinical manifestations

*Note: “4, 7, 11” rule → 4 (o more) out of 11 criteria (4 lab, 7 clinical) must be present, serially or simultaneously, for diagnosis
American College of Rheumatology, 1997 update

Etiology and Pathophysiology
- production of cytotoxic autoantibodies and immune complex formation
- multi-factorial etiology

- genetics
  - common association with HLA-B8/DR3; ~10% have positive family history
  - strong association with defects in apoptotic clearance → fragments of nuclear particles captured by antigen-presenting cells → develop anti-nuclear antibodies
  - cytokines involved in inflammatory process and tissue injury: B-lymphocyte stimulator (BlyS), IL-6, IL-17, IL-18, TNF-α

- environment
  - UV radiation, cigarette smoking, infection, vitamin D deficiency
  - estrogen
    - increased incidence after puberty, decreased incidence after menopause
    - men with SLE have higher concentration of estrogenic metabolites

- infection
  - viral (non-specific stimulant of immune response)

- drug-induced
  - anti-hypertensives (hydralazine), anti-convulsants (phenytoin), anti-arrhythmics (procanamide), isoniazid, biologics, oral contraceptive pills
  - anti-histone Abs are commonly seen in drug-induced SLE
  - symptoms resolve with discontinuation of offending drug

Epidemiology
- prevalence: 0.05% overall
- F:M = 10:1
- age of onset in reproductive yr (13–40)
- more common and severe in African-Americans and Asians
- bimodal mortality pattern
  - early (within 2 yr)
    - active SLE, active nephritis, infection secondary to steroid use
  - late (>10 yr)
    - inactive SLE, inactive nephritis, atherosclerosis likely due to chronic inflammation

Signs and Symptoms
- characterized by periods of exacerbation and remission
Table 15. Signs and Symptoms of SLE

</tr>
</tbody>
</table>

Investigations
- ANA (98% sensitivity, but poor specificity → used as a screening test; ANA titres are not useful to follow disease course)
- anti-dsDNA and anti-Sm are specific (95-99%)
- anti-dsDNA titre and serum complement (C3, C4) are useful to monitor treatment response in patients who are clinically and serologically concordant (anti-dsDNA, C3, and C4 also fluctuate with disease activity)
- antiphospholipid Ab (anti-cardiolipin Ab, SLE anticoagulant, An i-β2 glycoprotein-I Ab), may cause increased risk of clotting and increased aPTT

Treatment
- goals of therapy
  - treat early and avoid long-term steroid use, if unavoidable see Endocrinology, E40 for osteoporosis management
  - if high doses of steroids necessary for long term control, add steroid-sparing agents and taper when possible
  - treatment is tailored to organ system involved and severity of disease
  - all medications used to treat SLE require periodic monitoring for potential toxicity
- dermatologic
  - sunscreen, avoid UV light and estrogens
  - topical steroids, hydroxychloroquine
- musculoskeletal
  - NSAIDs ± gastroprotective agent for arthritis (also beneficial for pleuritis and pericarditis)
  - hydroxychloroquine improves long-term control and prevents flares
  - bisphosphonates, calcium, vitamin D to combat osteoporosis
- organ-threatening disease
  - high-dose oral prednisone or IV methylprednisolone in severe disease
  - steroid-sparing agents: azathioprine, MTX, mycophenolate mofetil
  - IV cyclophosphamide for serious organ involvement (e.g. cerebritis or lupus nephritis) see Nephrology, Systemic Lupus Erythematosus NP24 for clinical features of lupus nephritis

Antiphospholipid Antibody Syndrome

Definition
- multi-system vasculopathy manifested by recurrent thromboembolic events, spontaneous abortions, and thrombocytopenia
- often presents with migraine type H/As
- circulating antiphospholipid autoantibodies interfere with coagulation
- **primary APLS**: occurs in the absence of other disease
- **secondary APLS**: occurs in the setting of a connective tissue disease (including SLE), malignancy, drugs (hydralazine, procainamide, phenytoin, interferon, quinidine), and infections (HIV, TB, hepatitis C, infectious mononucleosis)
- **catastrophic APLS**: development within 1 wk of small vessel thrombotic occlusion in ≥3 organ systems with positive antiphospholipid Ab (high mortality)

Signs and Symptoms
- see clinical criteria in Table 16
- hematologic
  - thrombocytopenia, hemolytic anemia, neutropenia
- dermatologic
  - livedo reticularis, Raynaud’s phenomenon, purpura, leg ulcers, and gangrene

Treatment
- thrombosis
  - lifelong anti-coagulation with warfarin  
  - target INR 2.0-3.0 for first venous event, >3.0 for recurrent and/or arterial event
- recurrent fetal loss
  - heparin/low molecular weight heparin ± ASA during pregnancy
- catastrophic APLA
  - high-dose steroids, anti-coagulation, cyclophosphamide, plasmapheresis

Scleroderma (i.e. Systemic Sclerosis)

Definition
- a non-inflammatory autoimmune disorder characterized by widespread small vessel vasculopathy, production of autoantibodies, and fibroblast dysfunction causing fibrosis

![Scleroderma Types](image)

* Score of ≥9 is sufficient to classify a patient as having definite scleroderma (sensitivity 0.95, specificity 0.93)  
Arthritis & Rheum 2013;65(11):2737-2747
Etiology and Pathophysiology
- idiopathic vasculopathy (not vasculitis) leading to atrophy and fibrosis of tissues
- intimal proliferation and media mucinous degeneration → progressive obliteration of vessel lumen → fibrotic tissue
- resembles malignant HTN
- lung disease is the most common cause of morbidity and mortality

Epidemiology
- F:M = 3-4:1, peaking in 5th and 6th decades
- associated with HLA-DR1
- associated with environmental exposure (silica, epoxy resins, toxic oil, aromatic hydrocarbons, polyvinyl chloride)
- limited systemic sclerosis has a higher survival prognosis (>70% at 10 yr) than diffuse systemic sclerosis (40-60% at 10 yr)

</tbody>
</table>

Investigations
- blood work
  - CBC, Cr, ANA
  - anti-topoisomerase 1/anti-Scl-70: specific but not sensitive for diffuse systemic sclerosis
  - anti-centromere: favours diagnosis of CREST (limited systemic sclerosis)
- PFT
  - assess for interstitial lung disease
- imaging
  - CXR for fibrosis, echo for pulmonary HTN

Treatment
- dermatologic
  - good skin hygiene
  - low-dose prednisone (>20 mg may provoke renal crisis if susceptible), MTX (limited evidence)
- vascular
  - patient education on cold avoidance
  - vasodilators (CCBs, local nitroglycerine cream, systemic PGE2 inhibitors, PDE5 inhibitors)
- gastrointestinal
  - GERD: PPIs are first line, then H2-receptor agonists
  - small bowel bacterial overgrowth: broad spectrum antibiotics (tetracycline, metronidazole)
- renal disease
  - ACEI for hypertensive crisis
  - see Nephrology, NP32 for scleroderma renal crisis
- pulmonary
  - early interstitial disease: cyclophosphamide
  - pulmonary HTN: vasodilators (e.g. bosentan, epoprostenol, and PDE5 inhibitors)
- cardiac
  - pericarditis: systemic steroids
  - musculoskeletal
    - arthritis: NSAIDs
    - myositis: systemic steroids

Features of Pathologic Raynaud’s Syndrome
- New onset
- Asymmetric
- Precipitated by stimuli other than cold or emotion
- Associated with distal pulp pitting or tissue reabsorption
- Digit ischemia
- Capillary dilatation by capillaroscopy

Cyclophosphamine versus Placebo in Scleroderma Lung Disease

- **Study:** Double-blind, randomized, placebo-controlled trial
- **Outcome:** Lung function and health-related symptoms
- **Results:** The mean absolute difference in adjusted 12-month FVC percent predicted between cyclophosphamide and placebo groups was 2.55 percent, favouring cyclophosphamide. There were also treatment-related differences in physiological and symptom outcomes, and the difference in FVC was maintained at 24 months
- **Conclusion:** Cyclophosphamide has a significant but modest beneficial effect on lung function, dyspnea, thickening of skin and health-related quality of life in patients with symptomatic, scleroderma-related interstitial lung disease.
**Idiopathic Inflammatory Myopathy**

**Definition**
- autoimmune diseases characterized by proximal muscle weakness ± pain
- muscle becomes damaged by a non-suppurative lymphocytic inflammatory process
- associated with malignancy
  - increased risk of malignancy: age >50, DMM>PM, normal CK, refractory disease
  - associated with other connective tissue disease, Raynaud's phenomenon, autoimmune disorders

**Classification**
- PM/DMM
- adult and juvenile form

**Inclusion Body Myositis**
- age >50, M>F, slowly progressive, vacuoles in cells on biopsy
- suspect when patient unresponsive to treatment
- distal as well as proximal muscle weakness
- muscle biopsy positive for inclusion bodies

**POLYMYOSITIS/DERMATOMYOSITIS**

</tr>
</tbody>
</table>

*Definite if 4 present, probable if 3 present*  
*NEJM 1975;292:403-407*

**Etiology and Pathophysiology**
- PM is CD8 cell-mediated muscle necrosis, found in adults
- DMM is B-cell and CD4 immune complex-mediated, and causes peri-fascicular vascular abnormalities

**Signs and Symptoms**
- progressive symmetrical proximal muscle weakness (shoulder and hip) developing over weeks to months
  - difficulty lifting head off pillow, arising from chair, climbing stairs
  - dermatological
    - DMM has characteristic dermatological features (F>M, children and adults)
      - Gottron's papules
        - pink-violaceous, flat-topped papules overlying the dorsal surface of the interphalangeal joints
      - Gottron's sign
        - erythematous, smooth or scaly patches over the dorsal IPs, MCPs, elbows, knees, or medial malleoli
      - heliotrope rash: violaceous rash over the eyelids, usually with edema
      - shawl sign: poikilodermatous erythematous rash over neck, upper chest, and shoulders
      - mechanic's hands: dark, dry, thick scale on palmar and lateral surface of digits
      - periangual erythema
    - cardiac
      - arrhythmias, CHF, conduction defect, ventricular hypertrophy, pericarditis
    - gastrointestinal
      - oropharyngeal and lower esophageal dysphagia, reflux
    - pulmonary
      - weakness of respiratory muscles, ILD, aspiration pneumonia

**Investigations**
- blood work: CK, ANA, anti-Jo-1 (DMM), anti-Mi-2, anti-SRP
- imaging: MRI may be used to localize biopsy site
- EMG, muscle biopsy

**Malignancies Associated with DMM**
- Breast
- Lung
- Colon
- Ovarian

**Signs of DMM**
- Gottron’s papules and Gottron’s sign are pathognomonic of DMM (occur in 70% of patients)
Treatment
• non-pharmacological treatment
  • physical therapy and occupational therapy
• pharmacological treatment
  • high-dose corticosteroid (1-2 mg/kg/d) and slow taper
  • add immunosuppressive agents (azathioprine, MTX, cyclosporine)
  • IVIG if severe or refractory
  • hydroxychloroquine for DMM rash
• malignancy surveillance
  • detailed history and physical (breast, pelvic, and rectal exam)
  • CXR, abdominal and pelvic U/S, fecal occult blood, Pap test, mammogram ± CT scan (thoracic, abdominal, pelvic)

Sjögren’s Syndrome

Definition
• autoimmune condition characterized by dry eyes (keratoconjunctivitis sicca/xerophthalmia) and dry mouth (xerostomia), caused by lymphocytic infiltration of salivary and lacrimal glands
• may evolve into systemic disorder with diminished exocrine gland activity in respiratory tract and skin
• primary and secondary form (associated with RA, SLE, DMM, and HIV)
• prevalence, F>>M, 40-60 yo
• increased risk of non-Hodgkin’s lymphoma

Table 20. American College of Rheumatology Classification for Sjögren’s*

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Comments</th>
</tr>
</thead>
</table>
| 1. Positive serum anti-SSA/Ro and/or anti-SSB/La or positive RF and ANA titer > 1:320 | Focus scores are histopathologic grading systems
| 2. Labial salivary gland biopsy with focal lymphocytic sialadenitis with focus score ≥ 1 focus /4mm² | Strongly associated with phenotypic ocular and serological component’s of Sjögren’s
| 3. Keratoconjunctivitis sicca with ocular staining score > 3 | Ocular staining score based on fluorescein dye examination of conjunctiva and come to determine clinical changes

*Sjögren’s Syndrome classification criteria is met in patients with signs/symptoms of Sjögren’s, who have at least 2 of the above features

Signs and Symptoms
• “sicca complex”: dry eyes (keratoconjunctivitis sicca/xerophthalmia), dry mouth (xerostomia)
• staphylococcal blepharitis
• dental caries, oral candidiasis, angular cheilitis (inflammation and fissuring at the labial commissures of the mouth)
• systemic complications
  • sinusitis
  • autoimmune thyroid dysfunction
  • arthralgias, arthritis
  • subclinical diffuse ILD, xerotrachea leading to chronic dry cough
  • renal disease, glomerulonephritis
  • palpable purpura, vasculitis
  • peripheral neuropathy
  • lymphoma risk greatly increased

Treatment
• ocular
  • artificial tears or surgical punctal occlusion for dry eyes
• oral
  • good dental hygiene, hydration
  • parasympathomimetic agents that stimulate salivary flow (e.g. pilocarpine)
  • topical nystatin or clotrimazole x 4-6 wk for oral candidiasis
• systemic (e.g. hydroxychloroquine, corticosteroids)

Mixed Connective Tissue Disease
• syndrome with features of 3 different connective tissue diseases (e.g. SLE, scleroderma, PM)
• common symptoms: Raynaud’s phenomenon, swollen fingers
• blood work: anti-RNP (see Table 10)
• treatment is generally guided by the severity of symptoms and organ system involvement
• prognosis
  • 50-60% will evolve into SLE
  • 40% will evolve into scleroderma
  • only 10% will remain as MCTD for the rest of their lives
• cardiac involvement (arrhythmia) common, renal or lung involvement rare
Overlap Syndrome

- syndrome with sufficient diagnostic features of 2+ different connective tissue diseases

Vasculitides

- inflammation and subsequent necrosis of blood vessels leading to tissue ischemia or infarction of any organ system
- diagnosis
  - clinical suspicion: suspect in cases of unexplained multiple organ ischemia or systemic illness with no evidence of malignancy or infection; constitutional symptoms such as fever, weight loss, anorexia, fatigue
  - labs non-specific: anemia, increased WBC and ESR, abnormal U/A
  - investigations: biopsy if tissue accessible; angiography if tissue inaccessible
- treatment generally involves corticosteroids and/or immunosuppressive agents

Table 21. Classification of Vasculitis and Characteristic Features

<table>
<thead>
<tr>
<th>Classification</th>
<th>Characteristic Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMALL VESSEL</td>
<td></td>
</tr>
<tr>
<td>Non-ANCA-associated</td>
<td>Immune complex-mediated (most common mechanism)</td>
</tr>
<tr>
<td>Predominantly cutaneous vasculitis</td>
<td>Also known as hypersensitivity/leukocytoclastic vasculitis</td>
</tr>
<tr>
<td>IgA vasculitis (formely Henoch-Schönlein purpura [HSP]) (see Pediatrics, P86)</td>
<td>Vascular deposition of IgA causing systemic vasculitis (skin, GI, renal), usually self-limiting; most common in childhood</td>
</tr>
<tr>
<td>Cryoglobulinemic vasculitis (CV)</td>
<td>Systemic vasculitis caused by circulating cryoproteins forming immune complexes; 60-80% of cases are due to Hepatitis C, 5-10% are due to a CTD (SLE, RA, SS), 5-10% are due to a lymphoproliferative disorder and the remaining 5-10% are idiopathic or &quot;essential&quot;. CV may be associated with underlying infection (e.g. hepatitis C) or connective tissue disease</td>
</tr>
<tr>
<td>ANCA-associated (i.e. PR3-ANCA) Granulomatosis with polyangiitis (GPA, formerly Wegener’s)</td>
<td>Granulomatous inflammation of vessels of respiratory tract and kidneys; initially have URTI symptoms; most common in middle age</td>
</tr>
<tr>
<td>ANCA-associated (i.e. PR3-ANCA)</td>
<td></td>
</tr>
<tr>
<td>Cryoglobulinemic vasculitis (CV)</td>
<td></td>
</tr>
<tr>
<td>Eosinophilic granulomatosis with polyangiitis (Churg-Strauss syndrome) (50% ANCA positive)</td>
<td>Granulomatous inflammation of vessels with hypereosinophilia and eosinophilic tissue infiltration frequent lung involvement (asthma, allergic rhinitis), associated with MPO-ANCA in 40 50% of cases. Other manifestations include peripheral neuropathy (70%), GI involvement, myocardiitis and rare coronary arteries; average age 40s</td>
</tr>
<tr>
<td>Microangiopathic polyangiitis (70% ANCA positive, usually MPO)</td>
<td>Pauci-immune necrotizing vasculitis, affecting kidneys (necrotizing glomerulonephritis), lungs (capillaritis and alveolar hemorrhage), skin; most common in middle age</td>
</tr>
<tr>
<td>MEDIUM VESSEL</td>
<td></td>
</tr>
<tr>
<td>Polyarteritis nodosa</td>
<td>Segmental, non-granulomatous necrotizing inflammation Unknown etiology in most cases, any age (average 40-50s), M&gt;F</td>
</tr>
<tr>
<td>Kawasaki disease (see Pediatrics, P87)</td>
<td>Arteritis and mucocutaneous lymph node syndrome</td>
</tr>
<tr>
<td>LARGE VESSEL</td>
<td></td>
</tr>
<tr>
<td>GCA/Temporal arteritis</td>
<td>Inflammation predominantly of the aorta and its branches &gt;50 yr of age, F&gt;M</td>
</tr>
<tr>
<td>Takayasu’s arteritis</td>
<td>“Pulseless disease”, unequal peripheral pulses, chronic inflammation, most often the aorta and its branches Usually young adults of Asian descent, F&gt;M, risk of aortic aneurysm</td>
</tr>
</tbody>
</table>

OTHER VASCULITIDES

- Buerger’s disease ("Thromboangiitis Obliterans") | Inflammation and clotting of small and medium-sized arteries and veins of distal extremities, may lead to distal claudication and gangrene, most important etiologic factor is cigarette smoking. Most common in young Asian males |
| Behçet’s disease | Multi-system disorder presenting with ocular involvement (uveitis), recurrent oral and genital ulceration, venous thrombosis, skin and joint involvement; more common in Mediterranean and Asian, average age 30 yr old, M>F |
| Vasculitis mimicry (i.e. pseudovasculitis) | Cholesterol emboli, atrial myxoma, bacterial endocarditis (SBE), APLS |
Small Vessel Non-ANCA Associated Vasculitis

CUTANEOUS VASCULITIS

- subdivided into
  - drug-induced vasculitis
  - serum sickness reaction
  - vasculitis associated with other underlying primary diseases (CTD, infections, malignancies – hematologic > solid tumours)

Etiology and Pathophysiology

- cutaneous vasculitis following:
  - drug exposure (allopurinol, gold, sulfonamides, penicillin, phenytoin)
  - viral or bacterial infection
  - idiopathic causes

- small vessels involved (post-capillary venules most frequently)
- usually causes a leukocytoclastic vasculitis: debris from neutrophils around vessels
- sometimes due to cryoglobulins which precipitate in cold temperatures

Signs and Symptoms

palpable purpura ± vesicles and ulceration, urticaria, macules, papules, bullae, subcutaneous nodules
- renal or joint involvement may occur, especially in children

Investigations

- vascular involvement (both arteriole and venule) established by skin biopsy

Treatment

- stop possible offending drug
- NSAID, low dose corticosteroids
- immunosuppressive agents in resistant cases
- usually self-limiting

Small Vessel ANCA-Associated Vasculitis

GRANULOMATOSIS WITH POLYANGIITIS
(GPA formerly known as Wegener’s Granulomatosis)

Definition

- granulomatous inflammation of vessels that may affect the upper airways (rhinitis, sinusitis) lungs (pulmonary nodules, infiltrates), and kidneys (glomerulonephritis, renal failure)
- highly associated with c-ANCA by indirect immunofluorescence (IIF) and pR3-ANCA by ELISA; however, changes in ANCA levels do not predict remission or relapse
- incidence 2-3 per 100,000; more common in Northern latitudes

<td>Lungs show granulomas; kidneys show necrotizing segmental glomerulonephritis</td>
</tr>
</tbody>
</table>

*Diagnosed if 2 or more of the above 4 criteria present
American College of Rheumatology, 1990

Classic Features of GPA

- Necrotizing granulomatous vasculitis of lower and upper respiratory tract
- Focal segmental glomerulonephritis
Etiology
- pathogenesis depends on genetic susceptibility and environmental triggers (e.g. infection)
  - dysregulated immune response due to loss of B and T-cell tolerance
  - acute vascular injury mediated by neutrophils and monocytes

Signs and Symptoms
- systemic
  - malaise, fever, weakness, weight loss
- HEENT
  - sinusitis or rhinitis, nasal crusting and bloody nasal discharge, saddle nose deformity
  - proptosis due to inflammation/vasculitis involving extra-ocular muscles, granulomatous retrobulbar space occupying lesions or direct extension of masses from the upper respiratory tract
  - hearing loss due to involvement of CN VIII
- pulmonary
  - cough, hemoptysis, granulomatous upper respiratory tract masses
- renal
  - hematuria, proteinuria, elevated creatinine
- other
  - joint, skin, eye complaints, vasculitic neuropathy

Investigations
- blood work: anemia (normal MCV), increased WBC, increased Cr, increased ESR, elevated platelet count, ANCA (PR3 > MPO)
- urinalysis: proteinuria, hematuria, RBC casts
- CXR: pneumonitis, lung nodules, infiltrations, cavitary lesions
- biopsy: renal (segmental necrotizing glomerulonephritis), lung (granulomas, tracheobronchial erosion)
- c-ANCA and ESR often correlate with disease activity and used to monitor response to treatment in some patients

Treatment
- for severe, life or organ threatening disease
  - pulse methylprednisolone x 3 days followed by prednisone 1 mg/kg/d PO + cyclophosphamide 2 mg/kg/d PO for 36 mo OR rituximab 375 mg/m² followed by high dose MTX (20-25 mg PO/SC weekly) or azathioprine (2 mg/kg/d PO OD)
  - consider plasmapheresis in patients with rapidly deteriorating renal failure or pulmonary hemorrhage

Medium Vessel Vasculitis

POLYARTERITIS NODOSA

Definition
- systemic, necrotizing vasculitis of medium sized vessels
- ANCA negative
- 5-10% associated with hepatitis B positivity
- incidence 0.7 per 100,000; affects individuals between 40-60 yr; M:F = 2:1

Table 23. Classification Criteria for PAN*

<table>
<thead>
<tr>

<tr>
<td>7. Elevated Cr or BUN</td>
<td>Cr &gt;130 mg/dL (1.5 mg/dL, BUN &gt;14.3 mg/dL (40 mg/dL)</td>
</tr>
<tr>
<td>8. Hepatitis B positive</td>
<td>Presence of hepatitis B surface antigen or Ab</td>
</tr>
<tr>
<td>9. Arteriographic abnormality</td>
<td>Commonly aneurysms</td>
</tr>
<tr>
<td>10. Biopsy of artery</td>
<td>Presence of granulocytes and/or mononuclear leukocytes in the artery wall</td>
</tr>
</tbody>
</table>

*Diagnosed if 3 or more of the above 10 criteria present

Etiology and Pathophysiology
- focal panmural necrotizing inflammatory lesions in small and medium-sized arteries
- thrombosis, aneurysm, or dilatation at lesion site may occur
- healed lesions show proliferation of fibrous tissue and endothelial cells that may lead to luminal occlusion
Investigations
- blood work: CBC, ESR, Cr, BUN, p-ANCA, hepatitis B serology
- imaging: angiography
- arterial biopsy

Treatment
- prednisone 1 mg/kg/d PO and cyclophosphamide 2 mg/kg/d PO
  ± anti-viral therapy to enhance clearance of hepatitis B virus

**Large Vessel Vasculitis**

**GCA/TEMPORAL ARTERITIS**

<td>Temporal artery tenderness or decreased pulsations, not due to arteriosclerosis</td>
</tr>
<tr>
<td>4. Elevated ESR</td>
<td>ESR ≥50 mm/h</td>
</tr>
<tr>
<td>5. Abnormal artery biopsy</td>
<td>Mononuclear cell infiltration or granulomatous inflammation, usually with multinucleated giant cells</td>
</tr>
</tbody>
</table>

*Diagnosed if 3 or more of the above 5 criteria present. American College of Rheumatology, 1990

**Epidemiology**
- most frequent vasculitis in North America
- patients >50 yr
- F:M = 2:1
- North-South gradient (predominance in Northern Europe/US)
- affects extracranial arteries

**Signs and Symptoms**
- new onset temporal H/A ± scalp tenderness due to inflammation of involved portion of the temporal or occipital arteries
- sudden, painless loss of vision and/or diplopia due to narrowing of the ophthalmic or posterior ciliary arteries (PCA more common); can affect both eyes
- tongue and jaw claudication (pain in muscles of mastication on prolonged chewing)
- PMR (proximal myalgia, constitutional symptoms, elevated ESR) occurs in 30% of patients
- aortic arch syndrome (involvement of subclavian and brachial branches of aorta resulting in pulseless disease), aortic aneurysm ± rupture are late complications
- constitutional symptoms and shoulder/pelvic girdle pain and stiffness

**Investigations**
- diagnosis made by clinical suspicion, increased ESR, increased CRP, temporal artery biopsy, and possibly U/S or MRI

**Treatment**
- if suspect GCA, immediately start high dose prednisone 1 mg/kg in divided doses for approximately 4 wk, and then tapering prednisone as symptoms resolve; highly effective in treatment and in prevention of blindness and other vascular complications
- consider low dose ASA to help decrease visual loss

**Prognosis**
- increased risk of thoracic aortic aneurysm and aortic dissection
- yearly CXR ± abdominal U/S as screening

<tr>
<td>Motor Symptoms</td>
<td>+</td>
<td>–</td>
</tr>
</tbody>
</table>

Signs and Symptoms

- **axial**
  - mid and lower back stiffness, morning stiffness >1 h, night pain, persistent buttock pain, painful sacroiliac joint (+ FABER test)
  - spinal restriction (decreased ROM): lumbar (decreased Schöber), thoracic (decreased chest wall expansion, normal >5 cm at T4), cervical (global decrease, often extension first)
  - postural changes: decreased lumbar lordosis + increased thoracic kyphosis + increased cervical flexion = increased occiput to wall distance (>5 cm)

- **peripheral**
  - asymmetrical large joint arthritis, most often involving lower limb
  - enthesitis: tenderness over tibial tuberosity, or Achilles tendon and plantar fascia insertions into the calcaneus

- **extra-articular manifestations**
  - ophthalmic: acute anterior uveitis is common (25-30% patients)
  - renal: amyloidosis (late and rare), IgA nephropathy
  - gastrointestinal: IBD
  - cardiac: aortitis, aortic regurgitation, pericarditis, conduction disturbances, heart failure (rare)
  - respiratory: apical fibrosis (rare)
  - neurologic: cauda equina syndrome (rare)
  - skin: psoriasis

Investigations

- x-ray of SI joint: “pseudowidening” of joint due to erosion with joint sclerosis → bony fusion (late), symmetric sacroiliitis
- x-ray of spine: “squaring of edges” from erosion and sclerosis on corners of vertebral bodies (shiny corner sign) leading to ossification of outer fibres of annulus fibrosis (bridging syndesmophytes) → “bamboo spine” radiographically
- MRI of spine: assess activity in early disease; detection of cartilage changes, bone marrow edema, bone erosions, and subchondral bone changes. Best seen on T2 STIR (short tau inversion recovery) images (suppress fat and see bone edema)

Treatment

- **non-pharmacological therapy**
  - prevent fusion from poor posture and disability through: exercise (e.g. swimming), postural and deep breathing exercises, outpatient PT, smoking cessation

- **pharmacological therapy**
  - NSAIDs (first line of treatment)
  - glucocorticoids (topical eye drops, local injections)
  - DMARDs only for peripheral arthritis (sulfasalazine, MTX)
  - anti-TNF agents for axial and peripheral involvement
  - manage extra-articular manifestations

- **surgical therapy**
  - hip replacement and vertebral osteotomy for marked deformity

Prognosis

- spontaneous remissions and relapses are common and can occur at any age
- function may be excellent despite spinal deformity
- favourable prognosis if female and age of onset >40 yr
- early onset with hip disease may lead to severe disability; may require arthroplasty
**Enteropathic Arthritis**

- see *Gastroenterology, Inflammatory Bowel Disease, G19*
- MSK manifestations in the setting of either ulcerative colitis or Crohn's disease include peripheral arthritis (large joint, asymmetrical), spondylitis, and hypertrophic osteoarthropathy
- non-arthritic MSK manifestations can occur 2º to steroid treatment of bowel inflammation (arthralgia, myalgia, osteoporosis, AVN)
- NSAIDs should be used cautiously as they may exacerbate bowel disease

**Psoriatic Arthritis**

**Definition**
- arthritic inflammation associated with psoriasis

**Etiology and Pathophysiology**
- unclear but many genetic, immunologic, and some environmental factors involved (e.g. bacterial, viral, and trauma)

**Epidemiology**
- psoriasis affects 1% of population
- arthropathy in 15% of patients with psoriasis
- 15-20% of patients will develop joint disease before skin lesions appear

**Signs and Symptoms**

- **dermatologic**
  - well-demarcated erythematosus plaques with silvery scale
  - nail involvement: pitting, transverse or longitudinal ridging, discoloration, subungual hyperkeratosis, onycholysis, and oil drops
- **musculoskeletal**
  - 5 general patterns
    - asymmetric oligoarthritis (most common – 70%)
    - arthritis of DIP joints with nail changes
    - destructive in small joints
    - symmetric polyarthritis (similar to RA)
    - sacroiliitis and spondylitis (usually older, male patients)
  - other findings: dactylitis, enthesopathy
- **ophthalmic**
  - conjunctivitis, iritis (anterior uveitis)
- **cardiac and respiratory** (late findings)
  - aortic insufficiency
  - apical lung fibrosis
  - neurologic
  - cauda equina syndrome
- **radiologic**
  - floating syndesmophytes
  - pencil-in-cup appearance at IP joints
  - osteolysis, periostitis

**Treatment**
- treat skin lesions (e.g. steroid cream, salicylic acid/or retinoic acid, tar, UV light)
- NSAIDs or IA steroids
- DMARDs (methotrexate, sulfasalazine or leflunomide); biologic therapies to minimize erosive disease (use early if peripheral joint involvement). The latter include anti-TNF agents, anti-IL-17 (secukinumab) and anti-IL-12/23 (ustekinumab)

</table>

* To meet the CASPAR (Classification criteria for Psoriatic Arthritis) criteria, a patient must have inflammatory articular disease (joint, spine, or entheseal) with ≥3 points from the above 5 categories.

---

**Reactive Arthritis**

**Definition**
- one of the seronegative spondyloarthropathies in which patients have a peripheral arthritis (≥1 mo duration) accompanied by one or more extra-articular manifestations that appears shortly after certain infections of the GI or GU tracts
- this term should not be confused with rheumatic fever or viral arthritides.

**Etiology**
- onset following an infectious episode either involving the GI or GU tract
  - GI: *Shigella, Salmonella, Campylobacter, Yersinia, C. Difficile species*
  - GU: *Chlamydia* (isolated in 16-44% of ReA cases), *Mycoplasma species*
- acute clinical course
  - 1-4 wk post-infection
  - lasts weeks to years
  - often recurring
  - spinal involvement persists

**Epidemiology**
- in HLA-B27 patients, axial > peripheral involvement
- M>F

**Signs and Symptoms**
- **musculoskeletal**
  - peripheral arthritis, asymmetric pattern, spondylitis, Achilles tendinitis, plantar fasciitis, dactylitis
- **ophthalmic**
  - iritis (anterior uveitis), conjunctivitis
- **dermatologic**
  - keratoderma blennorrhagicum (hyperkeratotic skin lesions on palms and soles) and balanitis cinicata (small, shallow, painless ulcers of glans penis and urethral meatus) are diagnostic
- **gastrointestinal**
  - oral ulcers, diarrhea
- **urethritis and cervicitis**
  - sterile pyuria; presence not related to site of initiating infection

**Investigations**
- diagnosis is clinical plus laboratory
- blood work: normocytic, normochromic anemia, and leukocytosis
- sterile cultures
- serology: HLA-B27 positive

**Treatment**
- antibiotics for non-articular infections
- NSAIDs, physical therapy, exercise
- local therapy
  - joint protection
  - IA steroid injection
  - topical steroid for ocular involvement
- systemic therapy
  - corticosteroids, sulfasalazine, MTX (for peripheral joint involvement only)
  - TNF-α inhibitors for spinal inflammation

**Prognosis**
- self-limited, typically 3-5 mo, varies based on pathogen and patient’s genetic background
- chronic in 15-20% of cases

---

**Clinical Triad of Reactive Arthritis**
- Arthritis
- Conjunctivitis/uveitis
- Urethritis/cervicitis

**“Can’t See, Can’t Pee, Can’t Climb a Tree”**
Triad of conjunctivitis, urethritis, and arthritis is 99% specific (but 51% sensitive) for ReA

* 1st MTP = podagra
  *Ankle
  *Knee

Gout

**Definition**
- derangement in purine metabolism resulting in hyperuricemia; monosodium urate crystal deposits in tissues (tophi) and synovium (microtophi)

**Etiology and Pathophysiology**
- uric acid can be obtained from the diet or made endogenously by xanthine oxidase, which converts xanthine to uric acid
- an excess of uric acid results in hyperuricemia
- uric acid can deposit in the tissues (tophi), synovium (microtophi) and bones, where they can crystalize to form monosodium urate crystals that lead to gout
- both modifiable and non-modifiable risk factors contribute to gout
- non-modifiable risk factors include: genetic mutations, male gender and advanced age
- modifiable risk factors include: diet (alcohol, purine rich foods such as meats and seafoods, fructose/sugar sweetened foods; see list of precipitants below)
- other risk factors: renal failure, metabolic syndrome, diuretics

**Signs and Symptoms**
- single episode progressing to recurrent episodes of acute inflammatory arthritis
- *acute gouty arthritis*
  - severe pain, redness, joint swelling, usually involving lower extremities
  - joint mobility may be limited
  - attack will subside spontaneously within several days to weeks; may recur
- *tophi*
  - urate deposits on cartilage, tendons, bursae, soft tissues, and synovial membranes
  - common sites: first MTP, ear helix, olecanon bursae, tendon insertions (common in Achilles tendon)
- *kidney*
  - gouty nephropathy
  - uric acid calculi

**Investigations**
- joint aspirate: >90% of joint aspirates show crystals of monosodium urate (negatively birefringent, needle-shaped)
- x-rays may show tophi as soft tissue swelling, punched-out lesions, erosion with “over-hanging”
- correlated with hyperuricemia in the blood
- may see elevated WBC and ESR (nonspecific)

**Treatment**
- *acute gout*
  - NSAIDs: high dose, then taper as symptoms improve
  - corticosteroids: IA, oral, or intra-muscular (if renal, cardiovascular or GI disease and/or if NSAIDs contraindicated or failed)
  - colchicine within first 12 h but effectiveness limited by narrow therapeutic range
  - allopurinol can worsen an acute attack (do not start during acute flare)
  - OA (knee, wrist, 2nd and 3rd MCP)
  - Knee, wrist; monoarticular, or polyarticular
  - Erosions Chondrocalcinosis
  - First MTP classically; also midfoot, ankle, knee, or polarticular if chronic
  - Erosions Chondrocalcinosis
  - DA (knee, wrist, 2nd and 3rd MCP)
  - Acute: NSAIDs, corticosteroids, colchicine
  - Chronic: ± allopurinol, fuboxostat

Precipitants of Gout

- Drugs are FACT
  - Furosemide
  - Aspirin® (low dose)/Alcohol
  - Cystinotic drugs (cyclosperine)
  - Thiazide diuretics
  - Foods are SALT
    - Seafood
    - Alcohol (beer and spirits)
    - Liver and kidney
    - Turkey (meat)

10 Recommendations on the Diagnosis and Management of Gout

1. Identification of monosodium urate crystals should be performed for a definitive diagnosis of gout.
2. Gout/hyperuricemia should prompt investigations of renal function and CV risk factors.
3. Acid-gout should be treated with colchicine, NSAIDs, and/or glucocorticoids.
4. Patients should be counselled about lifestyle.
5. Allopurinol is first line forurate lowering therapy, with uricosurics as second line.
6. Patients should be informed about the risk of acute-gout flare with initiation of urate lowering therapy; colchicine prophylaxis should be considered.
7. Allopurinol can be used in patients with mild/moderate renal impairment with slow titration and monitoring.
8. Treatment goal is urine <0.36 mM and absence of attacks and resolution of tophi.
9. Tophi should be treated medically by lowering serum urate to <0.3 mM. Surgery is only for select cases.
10. Prophylactic pharmacological management of asymptomatic hyperuricemia is not recommended.
• chronic gout
  • conservative
    ◆ avoid foods with high purine content (e.g. visceral meats, sardines, shellfish, beans, peas)
    ◆ avoid drugs with hyperuricemic effects (e.g. pyrazinamide, ethambutol, thiazide, alcohol)
  • medical
    ◆ antihyperuricemic drugs (allopurinol and febuxostat): decrease uric acid production by inhibiting xanthine oxidase
    ◆ uricosuric drugs (probenecid, sulfinpyrazone): very rarely used in combination with allopurinol or febuxostat in patients in whom hyperuricemia is not controlled with the latter
  • prophylaxis prior to starting antihyperuricemic drugs (colchicine/low-dose NSAID)
  • in renal disease secondary to hyperuricemia, use low-dose allopurinol and monitor Cr

• indications for treatment with antihyperuricemic medications include
  • recurrent attacks (more than 2-3/yr), tophi, bone erosions, urate kidney stones
  • perhaps in renal dysfunction with very high urate load (controversial)

### Pseudogout (Calcium Pyrophosphate Dihydrate Disease)

**Definition**
- joint inflammation caused by calcium pyrophosphate crystals

**Etiology and Pathophysiology**
- acute inflammatory arthritis due to phagocytosis of IgG-coated CPPD crystals by neutrophils and subsequent release of inflammatory mediators within joint space
- more frequently polyarticular
- slower in onset in comparison to gout, lasts up to 3 wk but is self-limited

**Risk Factors**
- old age, advanced OA, neuropathic joints
- other associated conditions: hyperparathyroidism, hypothyroidism, hypomagnesemia, hypophosphatasia (low ALP), DM, hemochromatosis

**Signs and Symptoms**
- affects knees, wrists, MCPs, hips, shoulders, elbows, ankles, big toe
- multiple manifestations
- asymptomatic crystal deposition (seen on radiograph only)
- acute crystal arthritis (self-limited flares of acute inflammatory arthritis resembling gout)
- pseudo-OA (progressive joint degeneration, sometimes with episodes of acute inflammatory arthritis)
- pseudo-RA (symmetrical polyarticular pattern with morning stiffness and constitutional symptoms)
- acute may be triggered by dehydration, acute illness, surgery, trauma

**Investigations**
- must aspirate joint to rule out septic arthritis, gout
- CPPD crystals: present in 60% of patients, often only a few crystals, positive birefringence (blue) and rhomboid shaped
- x-rays show chondrocalcinosis in 75%: radiodensities in fibrocartilaginous structures (e.g. knee menisci) or linear radiodensities in hyaline articular cartilage

**Treatment**
- joint aspiration, rest, and protection
- NSAIDs: also used for maintenance therapy
- prophylactic colchicine PO (controversial)
- IA or oral steroids to relieve inflammation
Non-Articular Rheumatism

Definition
- disorders that primarily affect soft tissues or periarticular structures
- includes bursitis, tendinitis, tenosynovitis, fibromyalgia, and PMR

Polymyalgia Rheumatica

Definition
- characterized by pain and stiffness of the proximal extremities (girdle area)
- closely related to GCA (15% of patients with PMR develop GCA)
- no muscle weakness

Table 31. PMR Classification Criteria Scoring Algorithm*

<table>
<thead>
<tr>
<th>Points without</th>
<th>Points with Abnormal</th>
</tr>
</thead>
<tbody>
<tr>
<td>U/S (0-6)</td>
<td>U/S** (0-8)</td>
</tr>
</tbody>
</table>

- Morning stiffness duration > 45 min: 2 2
- Hip pain or limited ROM: 1 1
- Absence of RF or ACPA: 2 2
- Absence of other joint involvement: 1 1
- At least one shoulder with subdeltoid and/or biceps tenosynovitis and/or glenohumeral synovitis (either posterior or axillary) and at least one hip with synovitis and/or trochanteric bursitis on U/S: N/A 1
- Both shoulders with subdeltoid bursitis, biceps tenosynovitis, or gleno-humeral synovitis on U/S: N/A 1

*Required criteria: age ≥ 50 yr, bilateral shoulder aching, and abnormal ESR/CRP
**A score of 4 or more is categorized as PMR in the algorithm without U/S and a score of 5 or more is categorized as PMR in the algorithm with U/S
***Optional U/S criteria

Epidemiology
- incidence 50 per 100,000 per year in those >50 yr
- age of onset typically >50 yr, F:M = 2:1

Signs and Symptoms
- constitutional symptoms prominent (fever, weight loss, malaise)
- pain and stiffness of symmetrical proximal muscles (neck, shoulder and hip girdles, thighs)
- gel phenomenon (stiffness after prolonged inactivity)
- physical exam reveals tender muscles, but no weakness or atrophy

Investigations
- blood work: often shows anemia, elevated platelets, elevated ESR and CRP, and normal CK; up to 5% of PMR reported with normal inflammatory markers

Treatment
- goal of therapy: symptom relief
- start with prednisone dose of 15-20 mg PO OD, reconsider diagnosis if no response within several days
- taper slowly over 1 yr period with closely monitoring
- relapses should be diagnosed and treated on clinical basis; do not treat a rise in ESR as a relapse
- treat relapses aggressively (50% relapse rate)
- monitor for steroid side effects, glucocorticoid-induced osteoporosis prevention, and follow for symptoms of GCA
Fibromyalgia

Definition
- chronic (>3 mo), widespread (axial, left- and right-sided, upper and lower segment), non-articular pain with characteristic tender points

Diagnosis

Table 32. 2010 ACR Preliminary Diagnostic Criteria for Fibromyalgia

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Widespread Pain Index = number of areas in which the patient had pain over the last week (max score = 19): L and R: shoulder girdle, upper arm lower arm, hip, upper leg, lower leg, jaw One Area: chest, abdomen, upper back, lower back, neck</td>
<td>A patient satisfies diagnostic criteria for fibromyalgia if the following 3 conditions are met: 1. Widespread Pain Index (WPI) ≥ 7 and Symptom Severity (SS) scale score ≥ 5 or WPI 3–6 and SS scale score ≥ 9 2. Symptoms have been present at a similar level for at least 3 mo 3. The patient does not have a disorder that would otherwise explain the pain</td>
</tr>
<tr>
<td>Symptom Severity Score = sum of: a) severity of fatigue b) waking unrefreshed c) cognitive symptoms over the past week d) extent of somatic symptoms (IBS, H/A, abdominal pain/cramps, dry mouth, fever, hives, ringing in ears, vomiting, heartburn, dry eyes, SOB, loss of appetite, rash, hair loss, easy bruising, etc.) all (a-d) rated on 0-3 scale: 0 = no problem, 1 = mild 2 = moderate, 3 = severe</td>
<td></td>
</tr>
</tbody>
</table>

Epidemiology
- F:M = 3:1
- primarily ages 25–45 yr, some adolescents
- prevalence of 2-5% in general population
- overlaps with chronic fatigue syndrome and myofascial pain syndrome
- strong association with psychiatric illness

Signs and Symptoms
- widespread aching, stiffness
- easy fatigability
- sleep disturbance: non-restorative sleep, difficulty falling asleep, and frequent waking
- symptoms aggravated by physical activity, poor sleep, emotional stress
- patient feels that joints are diffusely swollen although joint examination is normal
- neurologic symptoms of hyperalgesia, paresthesias
- associated with irritable bowel or bladder syndrome, migraines, tension H/As, restless leg syndrome, obesity, depression, and anxiety
- physical exam should reveal only tenderness with palpation of soft tissues, with no specificity for trigger/tender points

Investigations
- blood work: includes TSH and ESR; all typically normal unless unrelated, underlying illness present
- serology: do not order ANA or RF unless there is clinical suspicion for a connective tissue disease
- laboratory sleep assessment

Differential Diagnosis
- diagnosis of exclusion
- rule out other disorders by history and physical exam (RA, SLE, PMR, myositis, hypothyroidism, hyperparathyroidism, neuropathies)
Common Medications

**Treatment**
- **non-pharmacological therapy**
  - education
  - exercise program (walking, aquatic exercises), physical therapy (good posture, stretching, muscle strengthening, massage)
  - stress reduction, CBT
- no evidence for alternative medicine such as biofeedback, meditation, acupuncture
- **pharmacological therapy**
  - low dose tricyclic antidepressant (e.g. amitriptyline)
  - for sleep restoration
  - select those with lower anticholinergic side effects
  - SNRI: duloxetine, milnacipran
  - anticonvulsant: pregabalin, gabapentin
  - analgesics may be beneficial for pain that interferes with sleep (NSAIDs, not narcotics)

**Prognosis**
- variable; usually chronic, unless diagnosed and treated early

Basic Anatomy Review

- recall that the anatomical position of the penis is erect; therefore, the anatomical ventral side of the penis appears to be the dorsal side of the flaccid penis.
Urologic History

- follow OPQRSTUVW approach
  - note that pain may not be limited to the genital region (e.g. lower abdomen, CVA)
- inquire about risk factors: past urologic disease (e.g. UTI, stones, STI, cancers, anatomic abnormalities), family Hx, medications, lifestyle factors (smoking, alcohol, inactivity), trauma, previous surgical procedures
- urinary habits
  - frequency of voiding, incontinence, nocturia
  - specific urinary symptoms include
    - storage symptoms: frequency, nocturia, incontinence, urgency (rush to toilet), stress (leak with cough/laughter)
    - voiding symptoms: straining, hesitancy, dysuria, intermittency, post-void dribbling, reduced stream, feeling of incomplete voiding
  - hematuria: blood clots, red/pink tinged urine
- sexual function
  - scrotal mass: see Scrotal Mass, U29
  - ED: see Erectile Dysfunction, U30
  - infertility: see Infertility, U34
- associated symptoms
  - N/V
  - bowel dysfunction
- constitutional symptoms
  - fever, chills, unintentional weight loss, night sweats, fatigue, malaise, bone pain

Always ask about sexual function on history. Change in erectile function can be one of the first symptoms that there is concomitant vascular disease. If there is new onset ED, consider screening for DM and CAD risk factors.
Hematuria (Blood in the Urine)

Macroscopic (Gross) Hematuria

Definition
- blood in the urine that can be seen with the naked eye

Classification
- see Nephrology, NP21

History
- timing of hematuria in urinary stream
  - initial: anterior urethra
  - terminal: bladder neck and prostatic urethra
  - total: bladder and/or above
- associated symptoms (storage and voiding)
  - pyuria, dysuria: UTI
  - flank pain, radiation: ureteral obstruction
- recent URTI: post-infectious glomerulonephritis, IgA nephropathy

Investigations
- CBC (rule out anemia, leukocytosis), electrolytes, Cr, BUN, INR, PTT
- urine studies
  - U/A, C&S, cytology
- imaging
  - CT contrast has largely replaced IVP to investigate upper tracts
  - consider contraindications: allergy, renal insufficiency, pregnancy
  - U/S alone may not be sufficient
  - cystoscopy to investigate lower tract (possible retrograde pyelogram)

Acute Management of Severe Bladder Hemorrhage
- manual irrigation via catheter with normal saline to remove clots
- Continuous Bladder Irrigation (CBI) using large (22-26 Fr) 3-way Foley to help prevent clot formation
- cystoscopy if active bleeding
  - identify resectable tumours
  - coagulate obvious sites of bleeding
- refractory bleeding
  - bilateral nephrostomy tube placement
  - hyperbaric oxygen
  - intravesical agents
  - continuous intravesical irrigation with 1% aluminum potassium sulfate solution as needed
  - intravesical instillation of 1% silver nitrate solution
  - intravesical instillation of 1-4% formalin (requires GA and pre-procedure cystogram to rule out reflux)
  - embolization or ligation of iliac branches
  - cystectomy and diversion (rarely performed)

Common Urologic Causes of Hematuria
 can be Classified as:

- TICS
  - Trauma/Tumour/Toxins
  - Infection/Inflammatory
  - Calculi/Cysts
  - Surgery/Sickle cell and other hematological causes

Upper Tract Imaging Options
- CT Urography (CTU): test of choice for renal parenchyma, calculi, and infections. Involves exposure to radiation and IV contrast (assess renal function and allergies)
- U/S: Superior to IVP for evaluation of renal parenchyma and renal cysts; limited sensitivity for UCC and small renal masses; U/S alone is insufficient for upper tract imaging
- Intravenous Pyelogram (IVP): Traditional option but rarely used (replaced by CTU); reasonable sensitivity for UCC, but poor sensitivity for RCC
**Microscopic Hematuria**

**Definition**
- blood in the urine that is not visible to the naked eye
- ≥2 RBCs/HPF on urinalysis of at least two separate samples

![Flowchart](image)

*Figure 6. Workup of asymptomatic microscopic hematuria*

Based on CUA Guidelines. Alternatively, the AUA recommends cystoscopy and CT urogram for all patients with confirmed microscopic hematuria; follow-up for negative workup is urinalysis yearly for two years, with repeat anatomic evaluation if microscopic hematuria persists.

---

**Lower Urinary Tract Dysfunction**

- see Gynecology for relevant female topics
- the lower urinary tract consists of the bladder and urethra. LUTD frequently involves both parts

**Voiding**

- two phases of lower urinary tract function
  1. storage phase (bladder filling and urine storage)
     - accommodation and compliance
     - no involuntary contraction(s)
  2. voiding phase (bladder emptying)
     - coordinated detrusor contraction
     - synchronous relaxation of outlet sphincters
     - no anatomic obstruction
- voiding dysfunction can therefore be classified as
  - failure to store: due to bladder or outlet
  - failure to void: due to bladder or outlet
- three types of symptoms
  - storage (formerly known as irritative)
  - voiding (formerly known as obstructive)
  - post-voiding

**Urinary Incontinence**

**Definition**
- involuntary leakage of urine

**Etiology**
- urgency incontinence
  - detrusor overactivity
    - CNS lesion, inflammation/infection (cystitis, stone, tumour), bladder neck obstruction (tumour, stone), BPH, idiopathic
    - decreased compliance of bladder wall (inability to store urine)
  - CNS lesion, fibrosis
  - sphincter/urethral problem
• stress urinary incontinence (SUI)
  • common in women; seen in men after prostate cancer treatment or pelvic operations
  • urethral hypermobility
    • weakened pelvic floor and musculofascial urethral and vaginal supporting mechanisms allows bladder neck and urethra to descend with increased intra-abdominal pressure
  • urethra is pulled open by greater motion of posterior wall of outlet relative to anterior wall
  • associated with childbirth, pelvic surgery, aging, levator muscle weakness, obesity
  • intrinsic sphincter deficiency (ISD): weakness of the urethra and associated smooth and striated muscle elements
  • pelvic surgery, neurologic problem, aging and hypoestrogen state
  • ISD and urethral hypermobility frequently co-exist
  • mixed incontinence
  • combination of stress and urgency incontinence
  • overflow incontinence
  • is a term sometimes used to describe urinary incontinence associated with urinary retention; for causes of urinary retention see Table 4
  • use of the term should be accompanied by the associated pathophysiology (e.g. BPH with overflow incontinence)

**Epidemiology**
• variable prevalence in women: 25-45%
• F:M = 2:1
more frequent in the elderly, affecting 5-15% of those living in the community and 50% of nursing home residents

**Table 3. Urinary Incontinence: Types and Treatments**

**Clinical Features**
• suprapubic pain (with acute retention), incomplete emptying, weak stream
• palpable and/or percussible bladder (suprapubic)
• possible purulent/bloody meatal discharge (with UTI)
• increased size of prostate or reduced anal sphincter tone on DRE
• neurological: presence of abnormal or absent deep tendon reflexes, reduced “anal wink”, saddle anesthesia
**Investigations**
- CBC, electrolytes, Cr, BUN, U/A and urine C&S, U/S, cystoscopy, urodynamic studies, PVR

**Treatment**
- treat underlying cause
- catheterization
  - acute retention
    - immediate catheterization to relieve retention; leave Foley in to drain bladder; follow-up to determine cause; closely monitor fluid status and electrolytes (risk of POD)
  - chronic retention
    - intermittent catheterization by patient may be used; definitive treatment depends on etiology
- suprapubic catheter if obstruction precludes urethral catheter
- for post-operative patients with retention:
  - encourage ambulation
  - α-blockers to relax bladder neck outlet
  - may need catheterization
  - definitive treatment will depend on etiology

---

**Benign Prostatic Hyperplasia**

**Definition**
- periurethral hyperplasia of stroma and epithelium in prostatic transition zone
- prostatic smooth muscle cells play a role in addition to hyperplasia

**Etiology**
- unknown
  - DHT required (converted from testosterone by 5-α reductase)
  - possible role of impaired apoptosis, estrogens, other growth factors

**Epidemiology**
- age-related, extremely common (50% of 50 yr olds, 80% of 80 yr olds)
- 25% of men will require treatment

**Clinical Features**
- result from outlet obstruction and compensatory changes in detrusor function
- voiding and storage symptoms
- DRE
  - prostate is smooth, rubbery, and may be symmetrically enlarged
- complications
  - retention
  - overflow incontinence
  - hydroureteronephrosis
  - renal insufficiency
  - infection
  - gross hematuria
  - bladder stones

**Investigations**
- Hx, assessing LUTS and impact on QOL
  - may include self-administered questionnaires (IPSS or AUA symptom index for severity, progression, and treatment response)
- P/E, including DRE
- U/A to exclude UTI
- Cr to assess renal function
- renal U/S to assess for hydroureteronephrosis
- PSA to rule out malignancy (see Prostate Cancer Screening, U26)
- uroflowmetry to measure flow rate (optional)
- PVR (optional)
- consider cystoscopy or bladder ultrasound prior to potential surgical management to evaluate outlet and prostate volume
- biopsy if suspicious for malignancy, i.e. elevated PSA or abnormal DRE

---

**Figure 7. Cross-section of prostate**

**Prostate size does not correlate well with symptoms in BPH**

**Approximate Prostate Sizes**

### Urethral Stricture

**Definition**
- decrease in urethral calibre due to scar formation in urethra (may also involve corpus spongiosum)
- M>F

**Etiology**
- congenital
  - failure of normal canalization (i.e. posterior urethral valves)
- trauma
  - instrumentation/catheterization (most common)
  - external trauma (e.g. burns, straddle injury)
  - foreign body
- infection
  - long-term indwelling catheter
  - STI (gonococcal or chlamydial disease)
- inflammation
  - balanitis xerotica obliterans (BXO; lichen sclerosis or chronic progressive sclerosing dermatosis of the male genitalia) causing meatal and urethral stenosis

**Clinical Features**
- voiding and storage symptoms
- urinary retention
- hydrotension
- related infections: recurrent UTI, secondary prostatitis/epididymitis

**Investigations**
- laboratory findings
  - flow rates <10 mL/s (normal ~20 mL/s) on uroflowmetry
  - urine culture usually negative, but U/A may show pyuria
- radiologic findings
  - RUG and VCUG will demonstrate location
  - cystoscopy

**Treatment**
- urethral dilatation
  - temporarily increases lumen size by breaking up scar tissue
  - healing will often reform scar tissue, recurrence of stricture
- visual internal urethrotomy (VIU)
  - endoscopically incise stricture
  - equal success rates to dilation with mid bulbar strictures <2 cm
  - high rate of recurrence (30-80%), avoid in younger patients
- open surgical reconstruction
  - complete stricture excision with anastomosis, ± urethroplasty depending on location and size of stricture

---

**Summary of Findings:**
- Men with planned cataract surgery should avoid starting β-adrenergic antagonists until after their surgery due to the risk of intraoperative floppy iris syndrome
- BPH Surgery
  - Absolute Indication
    - Renal failure with obstructive uropathy
    - Refractory urinary retention
  - Relative Indications
    - Recurrent UTI
    - Recurrent hematuria refractory to medical management
    - Renal insufficiency (rule out other causes)
    - Bladder stones

---

**Combination therapy vs. alpha blocker or SARI**

**Summary:**
- Men with baseline prostate volume ≥40mL and baseline PSA ≥1.5 ng/mL had greater reductions in RR of BPH-related surgery and RR of clinical progression on combined therapy compared to dutasteride monotherapy and than on tamsulosin monotherapy.

**Methods:** A 4 year combination of dutasteride and tamsulosin study was a multicentre double-blind RCT of outcomes in men ≥50 years old with symptomatic BPH, with PSA ≥1.5ng/mL and ≤10ng/mL, and prostate volume ≤30mL. Patients received tamsulosin, dutasteride or combination therapy. Primary endpoint was time to first acute urinary retention or BPH-related surgery; secondary endpoint was clinical progression of BPH/symptoms.

**Results:** Combination therapy resulted in significantly greater improvements in symptoms compared to dutasteride from 3 mo, and tamsulosin from 9 mo, and in BPH-related health status from 3 and 12 mo, respectively. There was a significant increase in ADE with combination therapy vs. monotherapies. However, withdrawal rates due to drug-related adverse events were similar across the treatment groups.

**Finasteride for Benign Prostatic Hyperplasia**

**Rationale:** To examine the effectiveness and safety of finasteride versus placebo or other active controls for the treatment of lower urinary tract symptoms.

**Summary of Findings:**
- 1. Finasteride improved urinary symptoms more than placebo in trials ≥1 yr duration and significantly lowered the risk of RUPH progression.
  - Compared with α-blockers, finasteride was less effective than either doxazosin or terazosin, but equally as effective as tamsulosin.
- 2. Symptom improvement with finasteride + doxazosin was equal to doxazosin alone.
- 3. Finasteride treatment resulted in an increased risk of ejaculation disorder, impotence and lowered libido compared with placebo.
- 4. Compared with doxazosin and terazosin, finasteride had a lower risk of orthostatic, dizziness, and postural hypotension.
Neurogenic Bladder

Definition
- dysfunction of the urinary bladder due to deficiency in some aspect of its innervation

Neurophysiology

Table 6. Efferent Sympathetic, Parasympathetic, and Somatic Nerve Supply

<table>
<thead>
<tr>
<th>Nerve Fibres</th>

<td>ACh/Muscarinic (M2 M3)</td>
<td>Detrusor</td>
</tr>
</tbody>
</table>

- stretch receptors in the bladder wall relay information to PMC and activate micturition reflex (normally inhibited by cortical input)
  - micturition
    - stimulation of parasympathetic neurons (bladder contraction)
    - inhibition of sympathetic and somatic neurons (internal and external sphincter relaxation, respectively)
  - urine storage
    - opposite of micturition
- voluntary action of external sphincter (pudendal nerve roots S2-S4) can inhibit urge to urinate
- cerebellum, basal ganglia, thalamus, and hypothalamus all have input at PMC in the brainstem

Examples of Neurologic Voiding Dysfunction
- neurogenic detrusor overactivity (NDO) (formerly termed detrusor hyperreflexia)
  - lesion above PMC (e.g. stroke, tumour, MS, Parkinson’s disease)
  - loss of voluntary inhibition of voiding
  - intact pathway inferior to PMC maintains coordination of bladder and sphincter
- detrusor sphincter dysynergia (DSD)
  - suprasacral lesion of spinal cord (e.g. trauma, MS, arteriovenous malformation, transverse myelitis)
  - loss of coordination between detrusor and sphincter (detrusor contracts on closed sphincter and vice versa)
  - component of detrusor overactivity as well
- detrusor atony/areflexia
  - lesion of sacral cord or peripheral efferents (e.g. trauma, DM, disc herniation, MS, congenital spinal cord abnormality, post abdominoperineal resection)
  - flaccid bladder which fails to contract
  - may progress to poorly compliant bladder with high pressures
- peripheral autonomic neuropathy
  - deficient bladder sensation → increasing residual urine → decompensation (e.g. DM, neurosyphilis, herpes zoster)
- muscular lesion
  - can involve detrusor, smooth/striated sphincter

Neuro-Urologic Evaluation
- Hx and P/E (urologic and general neurologic)
- voiding diary
- catheterization volumes in patients with CIC
- U/A, renal profile
- imaging
  - U/S to rule out hydronephrosis and stones; occasionally CT scanning with or without contrast
  - cystoscopy
  - urodynamic studies
    - uroflowmetry to assess flow rate, pattern
    - filling CMG to assess capacity, compliance, detrusor overactivity
    - voiding CMG (pressure-flow study) to assess bladder contractility and extent of bladder outflow obstruction
    - video study to visualize bladder/bladder neck/urethra during CMG using x-ray contrast
    - EMG and video ascertain presence of coordinated or uncoordinated voiding, allows accurate diagnosis of DSD

Treatment
- goals of treatment
  - prevent renal deterioration
  - prevent infections
  - achieve social continence

Microwave Thermotherapy for Benign Prostatic Hyperplasia

Purpose: To evaluate the efficacy and safety of microwave thermotherapy (TUMT) for men with symptomatic BPH with multiple comparison groups.

Selection Criteria: RCTs evaluating transurethral microwave therapy (TUMT) for men with symptomatic BPH with multiple comparison groups.

Results: 15 studies, 1,585 patients, mean age 66.8 yr, 3-6 mo duration. Mean urinary symptom scores decreased by 65% with TUMT and 77% with TURP. The pooled mean peak urinary flow increased by 70% with TUMT and 119% with TURP. Compared with TURP, TUMT was associated with decreased risks for retrograde ejaculation, treatment for strictures, hema uria, blood transfusions and transurethral resection syndrome, but increased risk of urinary retention and re-resection for BPH symptoms.

Conclusions: Overall, microwave thermotherapy techniques are effective alternatives to TURP and α-blockers for treating symptomatic BPH, although less effective than TURP in improving symptom score and urinary flow.

"Spinal shock", initially manifests as atonic bladder

Nerve roots in micturition: "S2-3-4 keeps the urine off the floor"
Lower Urinary Tract Symptoms (LUTS)

- clean intermittent catheterization (CIC)
- treatment options depend on status of bladder and urethra
  - bladder hyperactivity → anticholinergic medications to relax bladder (see Urinary Incontinence, U5)
    - refractory
      - botulinum toxin injections into bladder wall
      - occasionally augmentation cystoplasty (enlarging bladder volume and improving compliance
        by grafting section of detubularized bowel onto the bladder)
      - occasionally urinary diversion (ileal conduit or continent diversion) in severe cases if bladder
        management unsuccessful
  - flaccid bladder → CIC

Dysuria

Definition
- painful urination

Etiology

Table 7. Differential Diagnosis of Dysuria

<table>

Investigations
- focused Hx and P/E to determine cause (fever, d/c, conjunctivitis, CVA tenderness, back/joint pain)
  - any d/c (urethral, vaginal, cervical) should be sent for gonococcus/chlamydia testing; wet mount if vaginal d/c
  - U/A and urine C&S
  - if suspect infection, may start empiric ABx treatment (see Table 9, U12)
  - ± imaging of urinary tract (tumour, stones)

Hydronephrosis

- the upper urinary tract consists of the kidneys and ureters

Definition
- dilation of the renal pelvis and calyces caused by the impairment in antegrade urine flow

Etiology
- mechanical
  - congenital: see Congenital Abnormalities, U36
  - acquired
    - intrinsic: trauma, inflammation and bleeding, calculi, urologic neoplasms, BPH, urethral
      stricture, phimosis, previous urological surgery
    - extrinsic: trauma, neoplasms (uterine fibroid; colorectal, uterine, and cervical malignancies;
      lymphoma), aortic aneurysm, pregnancy (gravid uterus)
  - functional
    - neuropathic: neurogenic bladder, diabetic neuropathy, spinal cord disease
    - pharmacologic: α-adrenergic agonists
    - hormonal: pregnancy (progesterone decreases ureteral tone)

Investigations
- focused Hx, inquiring about pain (flank, lower abdomen, testes, labia), U/O, medication use, pregnancy, trauma, fever, Hx of UTIs, calculi, PID, and urological surgery
- CBC, electrolytes, Cr, BUN, U/A, C&S
- imaging studies (U/S is >90% sensitive and specific)
- MAG3 diuretic renogram: evaluates differential renal function and demonstrates if functional
  obstruction exists

Treatment
- hydronephrosis can be physiologic
- treatment should be guided at improving symptoms, treating infections, or improving renal function
- urgent treatment may require percutaneous nephrostomy tube or ureteral stenting to relieve pressure
overactive bladder

post-obstructive diuresis

definition
- polyuria resulting from relief of severe chronic obstruction
- >3 L/24 h or >200 cc/h over each of two consecutive hours

pathophysiology
- physiologic POD secondary to excretion of retained urea, Na⁺, and H₂O (high osmotic load) after relief of obstruction
  - self-limiting; usually resolves in 48 h with PO fluids but may persist to pathologic POD
- pathologic POD is a Na⁺-wasting nephropathy secondary to impaired concentrating ability of the renal tubules due to:
  - decreased reabsorption of NaCl in the thick ascending limb and urea in the collecting tubule
  - increased medullary blood flow (solute washout)
  - increased flow and solute concentration in the distal nephrons

management
- admit patient and closely monitor hemodynamic status and electrolytes (Na⁺ and K⁺ q6-12h and replace prn; follow Cr and BUN to baseline)
- monitor U/O q2h and ensure total fluid intake <U/O by replacing every 1 mL U/O with 0.5 mL ½ NS IV (PO fluids if physiologic POD)
- avoid glucose-containing fluid replacement (iatrogenic diuresis)

overactive bladder

definition
- a symptom complex that includes urinary urgency with or without urgency incontinence, urinary frequency (voiding ≥8 times in a 24 hr period), and nocturia (awakening ONE or more times at night to void)

etiology
- multiple etiologies proposed
- symptoms usually associated with involuntary contractions of the detrusor muscle
- may be associated with other conditions such as SUI in women and BPH in men (see Table 8)
- may be neurogenic, myogenic or idiopathic

epidemiology
- F:M = 1:1
- prevalence increases with age. 42% in males ≥75 years; 31% in females ≥75 years

diagnosis
- the diagnostic process should document symptoms that define overactive bladder and exclude other disorders that could cause the patient's symptoms
- minimal requirements for the process consist of:
  - focused history including past genitourinary disorders and conditions outlined in Table 8, questionnaires of LUTS for women and diaries of urination frequency, volume and pattern
  - P/E including genitourinary, pelvic and rectal examination
  - U/A to rule out hematuria and infection
- in some patients, the following investigations could be considered
  - post-void residual
  - cystoscopy to rule out recurrent infections, carcinoma in situ and other intravesical abnormalities
  - urodynamics to rule out obstruction in older men

treatment
- non pharmacological: behaviour therapies such as bladder training, bladder control strategies, pelvic floor muscle training, fluid management, and avoidance of caffeine, alcohol
- pharmacological
  - anti-muscarinics: oxybutynin hydrochloride, tolterodine, solifenacin, fesoterodine, or trospium
  - β3-adrenoceptor agonist: mirabegron
- refractory patients may be treated with:
  - neuromuscular-junction inhibition: botulinum toxin bladder injection
- others
  - percutaneous tibial nerve stimulation (not used commonly in Canada)
  - sacral neuromodulation
Infectious and Inflammatory Diseases

</table>

Infectious and Inflammatory Diseases

Antibiotic therapy should always be based on local resistance patterns and adjusted according to culture and sensitivity results.

Cystitis: Common Pathogens

KEEPS
- Klebsiella sp.
- E. coli (90%), other Gram-negatives
- Enterococci
- Proteus mirabilis, Pseudomonas
- S. saprophyticus

Acute uncomplicated pyelonephritis: suspected or confirmed Enterococcus infection requires treatment with ampicillin.

Urinary Tract Infection

- for UTIs during pregnancy, see Obstetrics, OB28

Definition
- symptoms suggestive of UTI + evidence of pyuria and bacteriuria on U/A or urine C&S
  - if asymptomatic + 100,000 CFU/mL = asymptomatic bacteriuria; only requires treatment in certain patients (e.g. pregnancy)

Classification
- uncomplicated: lower UTI in a setting of functionally and structurally normal urinary tract
- complicated: structural and/or functional abnormality, male patients, immunocompromised, diabetic, iatrogenic complication, pregnancy, pyelonephritis, catheter-associated
- recurrent: see Recurrent/Chronic Cystitis
**Risk Factors**
- stasis and obstruction
  - residual urine due to impaired urine flow e.g. PUVs, reflux, medication, BPH, urethral stricture, cysto- ele, neurogenic bladder
- foreign body
- introduce pathogen or act as nidus of infection e.g. catheter, instrumentation
- decreased resistance to organisms
- DM, malignancy, immunosuppression, spermicide use, estrogen depletion, antimicrobial use
- other factors
  - trauma, anatomic abnormalities, female, sexual activity, menopause, fecal incontinence

**Clinical Features**
- storage symptoms: frequency, urgency, dysuria
- voiding symptoms: hesitancy, post-void dribbling, dysuria
- other: suprapubic pain, hematuria, foul-smelling urine
- pyelonephritis – if present: typically presents with more severe symptoms (e.g. fever/chills, CVA, tenderness, flank pain)

**Organisms**
- typical organisms: KEEPS (E. coli 75-95%)
- atypical organisms
  - tuberculosis (TB)
  - Chlamydia trachomatis
  - Mycoplasma (Ureaplasma urealyticum)
  - fungi (Candida)

**Indications for Investigations**
- pyelonephritis
- persistence of pyuria/symptoms following adequate antibiotic therapy
- severe infection with an increase in Cr
- recurrent/persistent infections
- atypical pathogens (urea splitting organisms)
- Hx of structural abnormalities/decreased flow

**Investigations**
- U/A, urine C&S
  - UA: leukocytes ± nitrites ± hematuria
  - C&S: midstream, catheterized, or suprapubic aspirate
- if hematuria present, retest post-treatment, if persistent need hematuria workup (see Microscopic Hematuria, U5)
- U/S, CT scan if recurrent or treatment-resistant UTIs, suspected anatomic abnormalities, history indicates complicated cystitis

**Treatment**
- see Table 9, U12, Antibiotic Treatment of Urological Infections
- if febrile, consider admission with IV therapy and rule out obstruction

---

**Recurrent/Chronic Cystitis**

**Definition**
- ≥3 UTIs/yr

**Etiology**
- bacterial reinfection (80%) vs. bacterial persistence (relapse)
  - bacterial reinfection
    - recurrence of infection with either 1) a different organism, 2) the same organism if cultured >2 wk following therapy, or 3) with any organism with an intermittent sterile culture
  - bacterial persistence
    - same organism cultured within 2 wk of sensitivity-based therapy

**Investigations**
- assess predisposing factors
- investigations may include cystoscopy, U/S, CT

**Treatment**
- lifestyle changes (limit caffeine intake, increase fluid/H2O intake)
- ABx: continuous vs. post-coital
- post-menopausal women: consider topical or systemic estrogen therapy
- no treatment for asymptomatic bacteriuria except in pregnant women or patients undergoing urinary tract instrumentation

---

**Prevention of UTIs**
- Maintain good hydration (try cranberry juice)
- Wipe from front to back to avoid contamination of the urethra with feces from the rectum
- Avoid feminine hygiene sprays and scented douches
- Empty bladder immediately before and after intercourse
**Interstitial Cystitis**  
(Painful Bladder or Bladder Pain Syndrome)

**Definition**  
- bladder pain, chronic urgency and frequency without other reasonable causation

**Classification**  
- non-ulcerative (more common)  
- ulcerative

**Etiology**  
- unknown  
  - theories: increased epithelial permeability, autoimmune, neurogenic, defective GAG layer overlying mucosa

**Epidemiology**  
- prevalence: 20/100,000  
- 90% of cases are in females  
- mean age at onset is 40 yr (non-ulcerative tends to affect a younger to middle-aged population, while ulcerative tends to be seen in middle-aged to older)

**Clinical Features**  
- bladder pain, increase with filling and relief with emptying  
- glomerulations (submucosal petechiae) or Hunner’s lesions (ulcers) on cystoscopic examination  
- urinary urgency  
- negative U/A, urine C&S, and urine cytology

**Differential Diagnosis**  
- UTI, vaginitis, bladder tumour  
- radiation/chemical/eosinophilic/TB cystitis  
- eosinophilic/TB cystitis  
- bladder calculi

**Investigations**  
- Hx, P/E, urinalysis with microscopy

**Treatment**  
- first-line: patient empowerment (diet, lifestyle, stress management), pain management  
- second-line  
  - oral: pentosan polysulfate sodium, amitriptyline, cimetidine, hydroxyzine  
  - intravesical: dimethylsulfoxide (DMSO), heparin, lidocaine  
- third-line: cystoscopy with bladder hydrodistention (traditionally diagnostic) under GA, treat Hunner’s lesions if present  
- other: neuromodulation, cyclosporine A, intradetrusor botulinum toxin  
- surgery (last resort): augmentation cystoplasty, or urinary diversion ± cystectomy

**Acute Pyelonephritis**

**Definition**  
- infection of the renal parenchyma with local and systemic manifestations  
- clinical diagnosis of flank pain, fever and elevated WBC

**Etiology**  
- ascending (usually GN bacilli) or hematogenous route (usually GP cocci)  
- causative microorganisms  
  - gram positives: *Enterococcus faecalis, S. aureus, S. saprophyticus*  
  - gram negatives: *E. coli, Klebsiella, Proteus, Pseudomonas, Enterobacter*  
- common underlying causes of pyelonephritis  
  - stones, strictures, prostatic obstruction, vesicoureteric reflux, neurogenic bladder, catheters, DM, sickle-cell disease, PCKD, immunosuppression, post-renal transplant, instrumentation, pregnancy

**Clinical Features**  
- rapid onset (<24 h)  
- LUTS including frequency, urgency, hematuria; NOT dysuria unless concurrent cystitis  
- fever, chills, nausea, vomiting, myalgia, malaise  
- CVA tenderness and/or exquisite flank pain
Investigations
- U/A, urine C&S
- CBC and differential: leukocytosis, left shift
- imaging indicated if suspicious of complicated pyelonephritis or symptoms do not improve with 48-72 h of treatment
  - abdominal/pelvic U/S
  - CT
- nuclear medicine: DMSA scan can be used to help secure the diagnosis
  - a photopenic defect indicates active infection or scar; if normal alternative diagnoses should be considered

Treatment
- hemodynamically stable
  - outpatient oral ABx treatment ± single initial IV dose (see Table 9, U12)
- severe or non-resolving
  - admit, hydrate, and treat with IV ABx (see Table 9, U12)
- emphysematous pyelonephritis
  - most patients receive nephrectomy after IV ABx started and patient stabilized
  - consider temporization with nephrostomy tubes
- renal obstruction
  - admit for emergent stenting or percutaneous nephrostomy tube

Prostatitis/Prostatodynia

Epidemiology
- most common urologic diagnosis in men <50 yr
- prevalence 2-12%

Classification

<table>
<thead>
<tr>
<th>Table 10. Comparison of the Three Types of Prostatitis</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Category I: Acute Bacterial Prostatitis</strong></td>
</tr>
</tbody>
</table>
| Etiology | Ascending urethral infection with KEEPS: 80% *E. coli*
| Clinical Features | Acute onset fever, chills, malaise, pelvic pain, LUTS |
| Investigations | P/E: abdomen, external genitalia, perineum, prostate U/A, Blood CBC, C&S, Transrectal U/S if non-resolving/suspect prostatic abscess |
| Treatment | Supportive measures PO or IV ABx depending how sick (see Table 9, U12), May consider catheterization in patients with severe obstructive LUTS or retention |

**Category II: Chronic Bacterial Prostatitis**
- Recurrent exacerbations of acute prostatitis-like signs and symptoms
- Recurrent UTI with same organism

**Category III: Chronic Pelvic Pain Syndrome (CPPS) (Abacterial)**
- Divided into inflammatory (IIIA) and non-inflammatory (IIIB)
- Intraprostatic reflux of urine ± urethral hypertonia
- Multifactorial (immunological, neuropathic, neuroendocrine, psychosocial)

**Clinical Features**
- Same as per Category I + pelvic pain, LUTS

**Investigations**
- E: as per Category I + pelvic floor Urine C&S: 4-glass test VB1 (voided bladder): in tial (urethra) P/VB2: midstream (bladder) EPS (expressed prostatic secretions): not usually performed VB3: post-massage/DRE

**Treatment**
- Supportive measures ABx (see Table 9, U12), Consider addition of an β-blocker

*NIH-CPSI: National Institute of Health Chronic Prostatitis Symptom Index*
Epididymitis and Orchitis

Etiology
- common infectious causes
  - <35 yr: N. gonorrhoeae or Chlamydia trachomatis
  - ≥35 yr or penetrative anal intercourse: GI organisms (especially E. coli)
- other causes
  - mumps infection may involve orchitis, post-parotitis
  - TB
  - syphilis
  - granulomatous (autoimmune) in elderly men
  - amiodarone (involves only head of epididymis)
- chemical: reflux of urine into ejaculatory ducts

Risk Factors
- UTI
- unprotected sexual contact
- instrumentation/catheterization
- increased pressure in prostatic urethra (straining, voiding, heavy lifting) may cause reflux of urine along vas deferens → sterile epididymitis
- immunocompromise

Clinical Features
- sudden onset scrotal pain and swelling ± radiation along cord to flank
- scrotal erythema and tenderness
- fever
- storage symptoms, purulent d/c
- reactive hydrocele

Investigations
- U/A, urine C&S
- ± urethral d/c: Gram stain/culture
- if diagnosis uncertain, MUST rule out testicular torsion (U/S Doppler)

Treatment
- rule out torsion (see Investigations Table 24, U29)
- see Table 9, U12 for ABx therapy
- scrotal support, bed rest, ice, analgesia

Complications
- if severe → testicular atrophy
- 30% have persistent infertility problems

Urethritis

Etiology
- infectious or inflammatory (e.g. reactive arthritis)

Table 11. Infectious Urethritis: Gonococcal vs. Non-Gonococcal

<table>
<thead>
<tr>
<th>Causative Organism</th>

</tr>
</tbody>
</table>

Prehn’s Sign: pain may be relieved with elevation of testicles in epididymitis but not in testicular torsion (poor sensitivity, especially in children)

If unsure between diagnoses of epididymitis and torsion, always go to OR
Remember: torsion >6 h has poor prognosis

Reactive Arthritis (formerly known as Reiter’s syndrome)
Urethritis, uveitis (or conjunctivitis), and arthritis (can’t pee, can’t see, can’t climb a tree)

If culture negative or unresponsive to treatment consider: Ureaplasma urealyticum, Mycoplasma genitalium, Trichomonas vaginalis, HSV, or adenovirus
Stone Disease

Epidemiology
- prevalence: ~8% and increasing
- M:F = 2:1
- peak incidence 30-50 yr of age
- recurrence rate: 10% at 1 yr, 50% at 5 yr, 60-80% lifetime

Risk Factors
- hereditary: RTA, Glucose-6-phosphate dehydrogenase deficiency, cystinuria, xanthinuria, oxaluria, etc.
- lifestyle: minimal fluid intake; excess vitamin C, oxalate, purines, calcium
- medications: loop diuretics (furosemide, bumetanide), acetazolamide, topiramate, zonisamide, indinavir, acyclovir, sulfadiazine, triamterene
- medical conditions: UTI (with urea-splitting organisms: Proteus, Pseudomonas, Providencia, Klebsiella, Mycoplasma, Serrat a, S. aureus), myeloproliferative disorders, IBD, gout, DM, hypercalcemia disorders (hyperparathyroidism, tumour lysis syndrome, sarcoidosis, histoplasmosis), obesity (BMI >30)

Clinical Features
- urinary obstruction → upstream distention → pain
  - flank pain from renal capsular distention (non-colicky)
  - severe waxing and waning pain radiating from flank to groin, testis, or tip of penis from distended collecting system or ureter (ureteral colic)
  - writhing, persistent discomfort, nausea, vomiting, hematuria (90% microscopic), diaphoresis, tachycardia, tachypnea
- occasionally symptoms of trigonal irritation (frequency, urgency)
- bladder stones result in: storage and voiding LUTS, terminal hematuria, suprapubic pain
- if fever, rule out concurrent pyelonephritis and/or obstruction

Location of Stones
- calyx: may cause flank discomfort, persistent infection, persistent hematuria, or remain asymptomatic
- pelvis: tend to cause obstruction at UPJ, may cause persistent infection
- ureter: <5 mm diameter will pass spontaneously in 75% of patients

Stone Pathogenesis
- supersaturation of stone constituents (at appropriate temperature and pH)
- stasis, low flow, and low volume of urine (dehydration)
- crystal formation and stone nidus
- loss of inhibitory factors
  - citrate (forms soluble complex with calcium)
  - magnesium (forms soluble complex with oxalate)
  - pyrophosphate
  - Tamm-Horsfall glycoprotein
### Approach to Renal Stones

#### Treatment – Acute

- **medical**
  - analgesic ± antiemetic
  - NSAIDs help lower intra-ureteral pressure
  - medical expulsion therapy (MET)
    - α-blockers: increase rate of spontaneous passage in distal ureteral stones
    - ± Abx for bacteriuria
    - IV fluids if vomiting (note: IV fluids do NOT promote stone passage)
- **interventional**
  - required if obstruction endangers patient, e.g. sepsis, renal failure
  - first line: ureteric stent (via cystoscopy)
  - second line: image-guided percutaneous nephrostomy
  - admit if necessary
  - see *Indications for Admission to Hospital*

#### Treatment – Elective

- **medical**
  - likely conservative if ureteral stone <10 mm or kidney stone <5 mm and no complications/symptoms well controlled
  - stones <5 mm especially likely to pass spontaneously
  - PO fluids to increase urine volume to >2 L/d (3-4 L if cystine) and MET
  - specific to stone type (see Table 14)
  - periodic imaging to monitor stone position and assess for hydronephrosis
  - progress to interventional stone removal methods if symptoms worsen or fail to improve (indicating stone passage)

---

**Stones and Infection**

If septic, urgent decompression via ureteric stent or percutaneous nephrostomy is indicated. Definitive treatment of the stone should be delayed until the sepsis has cleared.

**Indications for PCNL**

- Size >2 cm
- Staghorn
- UPJ obstruction with correction of obstruction
- Calyceal diverticulum
- Cystine stones (poorly fragmented with ESWL)
- Anatomical abnormalities
- Failure of less invasive modalities

**24 h urine collections must be done AFTER discontinuing stone preventing/promoting medications**

**Indications for Admission to Hospital**

- Intractable pain
- Intractable vomiting
- Fever (suggests infection)
- Compromised renal function (including single kidney, bilateral obstructing stone)
- Pregnancy

**Detailed metabolic studies are NOT recommended unless complex patient (recurrent stone formers, pregnancy, pediatrics, strong family history, underlying kidney or systemic disease, etc.)**

---

Although hypercalciuria is a risk factor for stone formation, decreasing dietary calcium is NOT recommended to prevent stone formation. Low dietary calcium leads to increased GI oxalate absorption and higher urine levels of calcium oxalate.
• interventional
  • kidney
    • may stent prior to ESWL if stone is 1.5-2.5 cm
    • ESWL if stone <2 cm
    • PCNL if stone >2 cm
  • ureteral stones >10 mm
  • ESWL and URS are both first line treatment modalities for all locations
    – URS has significantly greater stone-free rates for stones at all locations in ureter, but also has higher complication rates (ureter perforation, stricture formation, etc.)
  • PCNL is second line treatment
  • laparoscopic or open stone removal (very rare)
  • bladder
    • transurethral stone removal or cystolitholapaxy
    • remove outflow obstruction (TURP or stricture dilatation)

Prevention
• dietary modification
  • increase fluid (>2 L/d), K+ intake
  • reduce animal protein, oxalate, Na*, sucrose, and fructose intake
  • avoid high-dose vitamin C supplements
• medications
  • thiazide diuretics for hypercalciuria
  • allopurinol for hyperuricosuria
  • potassium citrate for hypocitraturia, hyperuricosuria

Table 14. Stone Classification

Purpose: To determine whether or not α-blockers compared with other pharmacological treatments or placebo improve stone clearance rates and other clinically relevant outcomes in patients presenting with symptoms of stones less than 10 mm confirmed by imaging.

Results/Conclusions: 32 RCTs, 5,184 participants. Although patients using α-blockers were more likely to experience stone clearance compared to standard therapy, stone-free rates were significantly higher in the α-blocker group (RR 1.48, 95% CI 1.33-1.64), expulsion time was 2.81 days shorter, and there was a reduction in the number of pain episodes (MD -0.49, 95% CI -0.94 to -0.01), the need for analgesic medication (MD -10.17, 95% CI -16.93 to -1.41), and hospitalization (RR 0.35, 95% CI 0.13-0.81). α-blockers should therefore be offered as a primary treatment modality for ureteral stones.
# Approach to Renal Mass

**Urological Neoplasms**

**Figure 9. Workup of a renal mass**

*Imaging modality may be different in cases of contrast allergy or elevated creatinine*

## Benign Renal Neoplasms

### CYSTIC KIDNEY DISEASE
- simple cysts: usually solitary or unilateral
  - very common: up to 50% at age 50
  - usually incidental finding on abdominal imaging
  - Bosniak Classification is used to stratify for risk of malignancy based on cyst features from contrast CT
- polycystic kidney disease
  - autosomal recessive: multiple bilateral cysts, often leading to early renal failure in infants
  - autosomal dominant: progressive bilateral disease leading to HTN and renal failure, adult-onset
- medullary sponge kidney: cystic dilatation of the collecting ducts
  - usually benign course, but patients are predisposed to stone disease
- von Hippel-Lindau syndrome: multiple bilateral cysts or clear cell carcinomas (50% incidence of RCC)
  - renal cysts, cerebellar, spinal and retinal hemangioblastomas, pancreatic and epididymal cysts, pheochromocytomas

There is controversy over optimal management of small renal masses

Percutaneous needle biopsies of cystic renal masses may lead to peritoneal seeding

Tuberous Sclerosis
- Syndrome characterized by mental retardation, epilepsy, and adenoma sebaceum
- 45-60% of patients also present with angiomyolipomas which are often multiple and bilateral
RENAL CELL CARCINOMA

Etiology
- cause unknown
- originates from proximal convoluted tubule epithelial cells in clear cell subtype (most common)
- hereditary forms seen with von Hippel-Lindau syndrome and hereditary papillary renal carcinoma

Epidemiology
- 85% of primary malignant tumours in kidney
- M:F = 1.5:1
- peak incidence at 50-60 yr of age

Pathology
- histological subtypes: clear cell (75-85%), papillary (10-15%), chromophobic (5-10%), collecting duct
- sarcomatoid elements in any subtype is a marker of poor prognosis

Risk Factors
- top 3 risk factors: smoking, HTN, obesity
- miscellaneous: horseshoe kidney, acquired renal cystic disease
- role of environmental exposures (aromatic hydrocarbons, etc.) remains an unproven risk factor for development of RCC

Clinical Features
- usually asymptomatic; frequently diagnosed incidentally by U/S or CT
- indicators for poor prognosis: weight loss, weakness, anemia, bone pain
- classic “too late triad” found in 10-15%
  - gross hematuria 50%
  - flank pain <50%
  - palpable mass <30%
- metastases: seen in a 1/3 of new cases; additional 20-40% will go on to develop metastases (mostly in late presentations or large tumours)
  - bone, brain, lung and liver most common site
  - may invade renal veins and IVC lumen
- this may result in ascites, hepatic dysfunction, right atrial tumour, and pulmonary emboli

Investigations
- routine labs for paraneoplastic syndromes (CBC, ESR, LFTs, extended electrolytes)
- U/A
- renal U/S: solid vs. cystic lesion
- contrast-enhanced CT: higher sensitivity than U/S for detection of renal masses and for staging purposes
- MRI: useful for evaluation of vascular extension
- renal biopsy: to confirm diagnosis if considering observation or other non-surgical therapy

Staging
- involves CT, CXR, liver enzymes and LFTs, bone/head imaging (if symptoms dictate)
Clinical Features

- gross/microscopic hematuria
- flank pain
- storage or voiding symptoms (dysuria only if lower urinary tract involved)
- flank mass ± hydronephrosis (10-20%)
Investigations
- IVP/CT urogram
- cystoscopy and retrograde pyelogram

Treatment
- radical nephroureterectomy with excision of ipsilateral bladder cuff
- distal ureterectomy for distal ureteral tumours with concomitant ureteral reimplant
- emerging role for endoscopic laser ablation in patients with low grade disease, poor baseline renal health

Bladder Carcinoma

Etiology
- unknown, but environmental risk factors include:
  - smoking (main factor – implicated in 60% of new cases)
  - aromatic amines: naphthylamines, benzidine, tryptophan, phenacetin metabolites
  - cyclophosphamide
  - prior Hx of radiation treatment to the pelvis
  - *Schistosoma hematoobium* infection (associated with SCC)
  - chronic irritation: cystitis, chronic catheterization, bladder stones (associated with SCC)
  - aristolochic acid: associated with Balkan Nephropathy (renal failure, upper tract urothelial cancer) and Chinese Herbal Nephropathy

Epidemiology
- 2nd most common urological malignancy
- M:F = 3:1, more common among whites than blacks
- mean age at diagnosis is 65 yr

Pathology
- classification
  - urothelial carcinoma (UC) >90%
  - SCC 5-7%
  - adenocarcinoma 1%
  - others <1%
- stages and prognoses of urothelial carcinoma at diagnosis
  - non-muscle invasive (75%) → >80% overall survival
  - 15% of these will progress to invasive UC
  - majority of these patients will have recurrence
  - invasive (25%) → 50-60% 5 yr survival
  - 85% have no prior history of superficial UC (i.e. *de novo*)
  - 50% have occult metastases at diagnosis, and most of these will develop overt clinical evidence of metastases within 1 yr – lymph nodes, lung, peritoneum, liver
  - carcinoma *in situ* → flat, non-papillary erythematous lesion characterized by dysplasia confined to urothelium
  - more aggressive, worse prognosis
  - usually multifocal
  - may progress to invasive UCC

Clinical Features
- asymptomatic (20%)
- hematuria (key symptom: 85-90% at the time of diagnosis)
- pain (50%) → location determined by size/extent of tumour (i.e. flank, suprapubic, perineal, abdominal, etc.)
- clot retention (17%)
- storage urinary symptoms → consider carcinoma *in situ*
- palpable mass on bimanual exam → likely muscle invasion
- obstruction of ureters → hydronephrosis and uremia (nausea, vomiting, and diarrhea)

Investigations
- U/A, urine C&S, urine cytology
- U/S
- CT scan with contrast → look for filling defect
- cystoscopy with biopsy (gold standard) → establish diagnosis and to determine depth of penetration
- specific bladder tumour markers (e.g. NMP-22, BTA, Immunocyt, FDP)

Grading
- low grade: <10% invasive, 60% recur locally
- high grade: 50-80% are invasive or are expected to progress to invasive over time

Staging
- for invasive disease: CT or MRI, CXR, LFTs, extended electrolytes (Ca²⁺, Mg²⁺, PO₄³⁻) (metastatic workup)

The ENTIRE urinary tract must be evaluated in patients with hematuria unless there is clear evidence of glomerular bleeding (e.g. red cell casts, dysmorphic RBCs, etc.)

Cystoscopy is the initial procedure of choice for the diagnosis and staging of urothelial malignancy

Unexplained hematuria in any individual >40 yr old must be investigated to rule out a malignancy

Tumour grade is the single most important prognostic factor for progression

Non-Muscle-Invasive Bladder Cancer (NMIBC) and BCG

AHRQ Publication 2015:15-EHC017-EF #153

**Summary:** BCG is the only intravesical therapy associated with decreased risk of bladder cancer progression; however, it is also associated with high rate of adverse events. More research is needed to define optimal dose/regimen.

**Methods:** Review of Ovid Medline, Cochrane Central Register of Controlled Trials, Cochrane Database of SR, Health Technology Assessment, National Health Sciences Economic Evaluation, Database of Abstract of Reviews of Effects for studies on NMIBC interventions, including intravesical therapy.

**Results:** BCG is superior in prevention of bladder cancer recurrence compared to no intravesical therapy. BCG is superior to doxorubicin, epirubicin, and mitomycin in prevention of bladder cancer recurrence.

Treatment
- superficial (non-muscle invasive) disease: Tis, Ta T1
  - low-grade disease
  - TURBT ± intravesical chemotherapy (mitomycin C) to decrease recurrence rate
  - follow-up with cystoscopy and cytology
  - multifocal, or recurrent
  - TURBT ± intravesical chemio/immuno-therapy (e.g. BCG, mitomycin C) to decrease recurrence rate
  - T1 or CIS
  - repeat TURBT in 2-6 wk
  - maintenance with intravesical chemotherapy with BCG for 3 cycles every 3 mo, may be continued for 2-3 yr
- invasive disease: T2a, T2b, T3
  - radical cystectomy + pelvic lymphadenectomy with urinary diversion (e.g. ileal conduit, Indiana pouch, ileal neobladder) or TURBT + chemo-radiation (bladder sparing) for small tumours with non-obstructed ureters
  - neo-adjuvant chemotherapy prior to cystectomy may also be done
  - use of adjuvant chemotherapy after definitive local treatment is controversial
  - advanced/metastatic disease: T4a, T4b, N+, M+
    - initial combination of systemic chemotherapy ± irradiation ± surgery

Prognosis
- depends on stage, grade, size, number of lesions, recurrence and presence of CIS
  - T1: 90% 5 yr survival
  - T2: 55% 5 yr survival
  - T3: 30% 5 yr survival
  - T4/N+/M+: <5% 5 yr survival
Prostate Cancer

Etiology
- not known
- risk factors
  - age >50 yr, risk increases 1% per year after 65 yr
  - increased incidence in persons of African descent
  - high dietary fat (2x)
  - family Hx
    - 1st degree relative (2x)
    - 1st and 2nd degree relatives (9x)
  - positive BRCA mutation

Epidemiology
- most prevalent cancer in males
- 3rd leading cause of male cancer deaths (following lung and colon)
- up to 50% risk of CaP at age 50
- lifetime risk of death from CaP is 3%
- 75% diagnosed between ages of 60 and 85; mean age at diagnosis is 65

Pathology
- adenocarcinoma
  - >95%, often multifocal
- urothelial carcinoma of the prostate (4.5%)
  - associated with UC of bladder; does NOT follow TNM staging below; not hormone-responsive
- endometrial (rare)
  - carcinoma of the utricle

Anatomy (see Figure 7, U7)
- 60-70% of nodules arise in the peripheral zone
- 10-20% arise in the transition zone
- 5-10% arise in the central zone

Clinical Features
- usually asymptomatic
- most commonly detected by DRE, elevated PSA, or as an incidental finding on TURP
  - DRE: hard irregular nodule or diffuse dense induration involving one or both lobes
  - PSA: see Prostate Cancer Screening, U26
- locally advanced disease
  - storage and voiding symptoms, ED (all uncommon without spread)
- metastatic disease
  - bony metastases to axial skeleton common
  - visceral metastases are less common (liver, lung, and adrenal gland most common sites)
  - leg pain and edema with nodal metastases obstructing lymphatic and venous drainage

Methods of Spread
- local invasion
- lymphatic spread to regional nodes
  - obturator > iliac > presacral/para-aortic
- hematogenous dissemination occurs early

Investigations
- DRE
- PSA elevated in the majority of patients with CaP
- TRUS-guided needle biopsy
- bone scan may be omitted in untreated CaP with PSA <10 ng/mL
- CT scanning to assess metastases
- MRI: being investigated for possible role in detection, staging, MRI-guided biopsy and active surveillance

**Treatment**

- **T1/T2** (localized, low-risk)
  - if adequate life expectancy or no other significant comorbidities, consider active surveillance vs. definitive local treatment (RP, brachytherapy, or EBRT)
  - active surveillance for low risk, small volume Gleason 6 prostate cancer
  - no difference in cure or recurrence rates between definitive treatment modalities
  - in older population: watching waiting + palliative treatment for symptomatic progression
- **T1/T2** (intermediate or high-risk)
  - definitive therapy over active surveillance
- **T3, T4**
  - EBRT + androgen deprivation therapy or RP + adjuvant EBRT
  - N >0 or M >0
  - requires hormonal therapy/palliative radiotherapy for metastases; may consider combined androgen blockade
  - bila er orchiectomy – decreases testosterone production by 90%
  - GnRH agonists (e.g. leuprolide, goserelin)
  - GnRH antagonist (e.g. degarelix)
  - estrogens (e.g. diethylstilbestrol [DES])
  - antiandrogens (e.g. bicalutamide, enzalutamide)
  - local irradiation of painful secondaries or half-body irradiation
  - hormone-refractory prostate cancer
  - chemotherapy: docetaxel, cabazitaxel, sipuleucel-T

**Prognosis**

- **T1-T2**: comparable to normal life expectancy
- **T3-T4**: 40–70% 10 yr survival
- **N**+ and/or **M**+ 4% 5 yr survival
- prognostic factors: tumour stage, tumour grade, PSA value, PSA doubling time

<td>Incontinence (10%), ED (30-50%)</td>
</tr>
</tbody>
</table>

*Other options include cryosurgery, HIFU, hormonal ablation

**Digital Rectal Exam**

- should be included as part of initial screening
- suspicious findings: abnormal feeling, nodularity, focal lesion, discrete change in texture/fullness/symmetry

**Prostate Specific Antigen**

- glycoprotein produced by epithelial cells of prostate gland
- leaks into circulation in setting of disrupted glandular architecture
- value of <4 ng/mL traditionally considered as cut-off to differentiate normal from pathologic value, but no single justifiable cutpoint
- measured serum PSA is a combination of free (15%) and bound PSA (85%)
- PSA velocity, PSA density, and free:total PSA: all intended to increase sensitivity and specificity of serum PSA values
- decreased free:total PSA, elevated PSA velocity and elevated PSA density associated with increased CaP rates

**Screening Recommendations**

- conflicting evidence regarding mortality reduction with PSA-based screening and debate regarding overdiagnosis/overtreatment

---

1. 10 Year Outcomes After Monitoring, Surgery, or Radiotherapy for Localized Prostates Cancer  
   NEJM 2016;375(15):1415-1424  
   Summary: At 10 years, prostate-cancer-specific mortality was low regardless of the treatment, with no significant difference among treatments. Surgery and radiotherapy were associated with lower incidences of disease progression and metastasis vs. active monitoring.  
   Methods: 1643 men randomized into active monitoring (45%), surgery (55%), and radiotherapy (5%)  
   - Primary outcome: prostate-cancer mortality at median 10 year follow-up.  
   - Secondary outcomes: rate of disease progression, metastases, and all-cause deaths.  
   Results: 1. Primary outcome: prostate-cancer-specific deaths overall; 8 in active-monitoring group, 5 in the surgery group, and 4 in the radiotherapy group; difference among the groups was not significant (p=0.4). No significant difference was seen among groups in numbers of deaths from any cause (189 deaths overall; p=0.87).  
   2. Secondary outcomes: metastases developed more in active monitoring group (33 men) vs. surgery group (13 men) or radiotherapy group (18 men) (overall p=0.004). Higher rates of disease progression in active-monitoring group (112 events) vs. surgery group (46 events) or radiotherapy group (46 events) (p<0.001 for the overall comparison).

---

2. Prostate Cancer Screening  
   Long-Term Follow-Up on PSA Screening  
   Lancet 2014;384(9959):2027-2035  
   Summary: With 13 yr follow-up, the mortality reduction remains unchanged (21%, and 29% after non-compliance adjustment). However, the number needed to screen to treat is decreasing, and is now below the number needed to screen observed in breast cancer trials.  
   Methods: multi-centre RCT with predefined central monitoring (545), surgery (553), and radiotherapy (545)  
   - Primary outcome: prostate-cancer mortality at 10 years follow-up in the intervention arm was compared to control arm.  
   - Secondary outcomes: rate of disease progression, metastases, and all-cause deaths.  
   Results: RR of PCa incidence between intervention and control arms was 1.91 after 9yr follow-up, 1.86 at 11yr follow-up, and 1.67 at 13yr follow-up.  
   - RR of PCa mortality was 0.85, 0.78, and 0.79, at 9, 11, 13 yr follow-up, respectively. RRR is 21%, and ARR from death is 1.28 per 1000 men.  
   - Causes of Increased PSA  
     BPH, prostatitis, prostatic ischemia/infarction, prostate biopsy/surgery, prostatic massage, acute urinary retention, urethral catheterization, cystoscopy, TRUS, strenuous exercise, perineal trauma, ejaculation, acute renal failure, coronary bypass graft, radiation therapy  
   - PSA is specific to the PROSTATE, but NOT to prostate cancer
• Long-Term Care and United States Preventative Services Task Force all recommend against PSA testing as a population wide screening tool
• however, serum PSA screening recommended in any man with >10 yr life-expectancy and any of the following
  - suspicious finding on DRE
  - moderate-severe LUTS
  - high risk individuals
  - investigating secondary carcinoma of unknown origin to rule out CaP as primary

**Canadian Urological Association Guidelines (2011) re: CaP Screening**
• harms and benefits of PSA testing must be explained to the patient and an informed, shared decision to test must be established
• initial screening should include both serum PSA and DRE
• all men should be offered screening at age 50 if >10 yr life-expectancy
• high-risk individuals (family Hx of CaP or African ancestry) should be offered screening at age 40 if >10 yr life-expectancy
• standard has been annual screening, but q2-4yr screening acceptable
• no strict cutpoint for when to biopsy; decision to biopsy should be based on more than a single PSA value
• AUA guidelines recommend against universal routine PSA screening for CaP

**Testicular Tumours**

**Etiology/Risk Factors**
• cryptorchidism, atrophy, sex hormones, HIV infection, infertility, family Hx, past Hx of testicular cancer

**Epidemiology**
• rare, but most common solid malignancy in young males 15-35 yr
• any solid testicular mass or acute hydrocoele in young patient – must rule out malignancy
• slightly more common in right testis (corresponds with slightly higher incidence of right-sided cryptorchidism)
• 2-3% bilateral (simultaneously or successively)

**Pathology**
• primary
  - 1% of all malignancies in males
  - cryptorchidism has increased risk (10-40x) of malignancy
  - 95% are germ cell tumours (all are malignant)
    - seminoma (35%) → classic, anaplastic, spermatocytic
    - NSGCT → embryonal cell carcinoma (20%), teratoma (5%), choriocarcinoma (<1%), yolk sac (<1%), mixed cell type (40%)
  - 5% are non-germ cell tumours (usually benign) → Leydig (testosterone, precocious puberty), Sertoli (gynecomastia, decreased libido)
• secondary
  - male >50 yr
  - usually lymphoma or metastases (e.g. lung, prostate, GI)

**Clinical Features**
• painless testicular enlargement (painful if intratesticular hemorrhage or infarction)
• dull, heavy ache in lower abdomen, anal area or scrotum
• associated hydrocele (10%)
• coincidental trauma (10%)
• infertility (rarely presenting complaint)
• gynecomastia due to secretory tumour effects
• supraclavicular and inguinal lymphadenopathy
• abdominal mass (retroperitoneal lymph node mets)

**Methods of Spread**
• local spread follows lymphatics
  - right → medial, paracaval, anterior and lateral nodes
  - left → left lateral and anterior paraaortic nodes
  - “cross-over” metastases from right to left are fairly common, but no reports from left to right
  - hematogenous most commonly to lung, liver, bones, and kidney

**Investigations**
• diagnosis is established by pathological evaluation of specimen obtained by radical inguinal orchidectomy
• tumour markers (β-hCG, LDH, AFP)
  - β-hCG and AFP are positive in 85% of non-seminomatous tumours
  - elevated marker levels return to normal post-operatively if no metastasis
  - β-hCG positive in 7% of pure seminomas, AFP never elevated with seminoma
Urological Neoplasms

• testicular U/S (hypoechoic area within tunica albuginea = high suspicion of testicular cancer)
• evidence of testicular microlithiasis is not a risk factor for testicular cancer
• needle aspiration contraindicated

Staging
• clinical: CXR (lung mets), markers for staging (β-hCG, AFP, LDH), CT abdomen/pelvis (retroperitoneal lymphadenopathy)
  ▪ Stage I: disease limited to testis, epididymis, or spermatic cord
  ▪ Stage II: disease limited to the retroperitoneal nodes
  ▪ Stage III: disease metastatic to supradiaphragmatic nodal or visceral sites

Table 22. 2010 TNM Classification of Testicular Carcinoma

Management
• orchiectomy through inguinal ligament for all stages
• consider sperm banking, testicular prosthesis
• adjuvant therapies (see figure 13)

Prognosis
• 99% cured with stage I and II disease
• 70-80% complete remission with advanced disease

Penile Tumours

Epidemiology
• rare (<1% of cancer in males in U.S.)
• most common in 6th decade

Benign
• cyst, hemangioma, nevus, papilloma

Pre-Malignant
• balanitis xerotica obliterans, leukoplakia, Buschke-Lowenstein tumour (large condyloma)

Pre-invasive Cancer
• carcinoma in situ
  ▪ Bowen's disease → crusted, red plaques on the shaft
  ▪ erythroplasia of Queyrat → velvet red, ulcerated plaques on the glans
  ▪ treatment options: local excision, laser, radiation, topical 5-fluorouracil

Figure 13. Adjuvant management of testicular cancer post-orchiectomy

Adapted from Dr. MAS Jewett
Malignant
• risk factors
  ▪ chronic inflammatory disease
  ▪ STI
  ▪ phimosis
  ▪ uncircumcised penis
• 2% of all urogenital cancers
• SCC (>95%), basal cell, melanoma, Paget’s disease of the penis (extremely rare)
• definitive diagnosis requires full thickness biopsy of lesion
• lymphatic spread (superficial/deep inguinal nodes → iliac nodes) >> hematogenous

Treatment
• wide surgical excision with tumour-free margins (dependent on extent and area of penile involvement)
  ± lymphadenectomy
• consider less aggressive treatment modalities in CIS (cryotherapy, laser therapy, etc.) if available

### Scrotal Masses

</tr>
<tr>
<td>Treatment</td>
<td>Conservative Surgical ligation of testicular veins Percutaneous vein occlusion (balloon, sclerosing agents) Repair may improve sperm count/motility 50-75%</td>
<td>Conservative Avoid needle aspiration as it can lead to infection, reaccumulation and spilling of irritating sperm within scrotum</td>
<td>Conservative Needle drainage Surgical</td>
<td>Emergency surgical exploration and bilateral orchiectomy Definitive diagnosis NOT necessary to take to OR Orchiectomy if poor prognosis</td>
<td>Surgical repair</td>
</tr>
</tbody>
</table>
TORSION OF TESTICULAR APPENDIX
- twisting of testicular/epididymal vestigial appendix

Signs and Symptoms
- clinically similar to testicular torsion, but vertical lie and cremaster reflex preserved
- "blue dot sign"
  - blue infarcted appendage seen through scrotal skin in children (can usually be palpated as small, tender lump)

Treatment
- analgesia – most will subside over 5-7 d
- surgical exploration and excision if refractory pain

HEMATOCELE
- trauma with bleed into tunica vaginalis
- U/S helpful to exclude fracture of testis which requires surgical repair

Treatment
- ice packs, analgesics, surgical repair

Erectile Dysfunction

Definition
- consistent (>3 mo duration) or recurrent inability to obtain or maintain an adequate erection for satisfactory sexual performance

Physiology
- erection involves the coordination of psychologic, neurologic, hemodynamic, mechanical, and endocrine components
- nerves: sympathetic (T11-L2), parasympathetic (S2-4), somatic (dorsal penile/pudendal nerves [S2-4])
- erection (“POINT”)
  - parasympathetics → NO release → increased cGMP within corpora cavernosa leading to:
    1. arteriolar dilatation
    2. sinusoidal smooth muscle relaxation → increased arterial inflow and compression of penile venous drainage (decreased venous outflow)
• emission (“SHOOT”)
  - sensory afferents from glans
  - secretions from prostate, seminal vesicles, and ejaculatory ducts enter prostatic urethra (sympathetics)
• ejaculation ("SHOOT")
  - bladder neck closure (sympathetic)
  - spasmodic contraction of bulbocavernosus and pelvic floor musculature (somatic)
• detumescence
  - sympathetic nerves, norepinephrine, endothelin-1 → arteriolar and sinusoidal constriction → penile flaccidity

*Combination can co-exist

Etiology ("IMPOTENCE")

• Iatrogenic: pelvic surgery, pelvic radiation
• Mechanical: Peyronie’s, post-priapism
• Psychological: depression, stress, anxiety, PTSD, widower syndrome
• Occlusive: arterial HTN, DM, smoking, hyperlipidemia, PVD, impaired veno-occlusion
• Trauma: penile/pelvic, bicycling
• Extra factors: renal failure, cirrhosis, COPD, sleep apnea, malnutrition
• Neurogenic: CNS (e.g. Parkinson’s, MS, spinal cord injury, spina bifida, stroke), PNS (e.g. DM, peripheral neuropathy)
• Chemical: antihypertensives, sedatives, antidepressants, anxiolytics, anticholinergics, antihistamines, anti-androgens (including 5-a reductase inhibitors), statins, GnRH agonists, illicit drugs
• Endocrine: DM, hypogonadism, hyperprolactinemia, hypo/hyperthyroid

Diagnosis

• complete Hx (include sexual, medical, and psychosocial aspects)
• self administered questionnaires (e.g. International Index of Erectile Function, Sexual Health Inventory for Men Questionnaire, ED Intensity Scale, ED Impact Scale)
• focused P/E, including vascular and neurologic examinations, secondary sexual characteristics
• lab investigations, dependent on clinical picture
  - risk factor evaluation: fasting blood glucose or HbA1c, cholesterol profile
  - optional: TSH, CBC, U/A, testosterone (free and total), prolactin, LH
• specialized testing including nocturnal penile tumescence monitoring usually unnecessary
• evaluation of penile vasculature only relevant with past history of trauma (i.e. pelvic fracture)

Treatment

• can often be managed by family doctor, see sidebar for when to refer
• must fully inform patient/partner of options, benefits and complications
• non-invasive
  - lifestyle changes (alcohol, smoking), psychological (sexual counselling and education)
  - change precipitating medications
  - treat underlying causes (DM, CVD, HTN, endocrinopathies)
• minimally invasive
  - oral medication (see Common Medications, U42)
    - sildenafil, tadalafil, vardenafil, avanafil (not available in Canada): inhibits PDE-5 to increase intracavernosal cyclic GMP levels
    - all four have similar effectiveness, difference in onset of action is not clinically significant
      - tadalafil has longer half-life, no cyanopsia, and can be taken on empty or full stomach
    - vacuum devices: draw blood into penis via negative pressure, then put ring at base of penis
    - MUSE: male urethral suppository for erection – vasoactive substance (PGE1) capsule inserted into urethra
• invasive
  - intracavernous vasodilator injection/self-injection
    - triple therapy (papaverine, phentolamine, PGE1) or PGE1 alone
    - complications: priapism (overdose), fibrosis of tunica albuginea at site of repeated injections (Peyronie's plaque) and injection site injuries (pain, hematoma, etc.)
• surgical
  - penile implant (last resort): malleable or inflatable
  - penile artery reconstruction (in young men with isolated vascular lesion – investigational)
**Trauma**

- see Emergency Medicine, ER7

---

**Renal Trauma**

**Classification According to Severity**

- minor
  - contusions and superficial lacerations/hematomas: 90% of all blunt traumas, surgical exploration seldom necessary
- major
  - laceration that extends into medulla and collecting system, major renal vascular injury, shattered kidney

**Etiology**

- 80% blunt MVC, assaults, falls) vs. 20% penetrating (stab wounds and gunshots)

**Clinical Features**

- mechanism of injury raises suspicion
- can be hemodynamically unstable secondary to renal vascular injury and/or other sustained injuries ABCs
- upper abdominal tenderness, flank tenderness, flank contusions, lower rib/vertebral transverse process fracture

**Investigations**

- U/A
  - hematuria: requires workup but degree does not correlate with the severity of injury
- imaging
  - CT (contrast, triphasic) if patient stable: look for renal laceration, extravasation of contrast, retroperitoneal hematoma, and associated intra-abdominal organ injury

**Staging (does not necessarily correlate well with clinical status)**

- I: contusion/hematoma
- II: <1 cm laceration without urinary extravasation
- III: >1 cm laceration without urinary extravasation
- IV: laceration causing urinary extravasation and/or main arterial or vein injury with contained hematoma
- V: shattered kidney or avulsion of pedicle

**Treatment**

- microscopic hematuria + isolated well-staged minor injuries → no hospitalization
- gross hematuria + contusion/minor lacerations → hospitalize, bedrest, repeat CT if bleeding persists
- surgical intervention/minimally invasive angiography and embolization
  - absolute indications
    - hemorrhage and hemodynamic instability
  - relative indications
    - non-viable tissue and major laceration
    - urinary extravasation
    - vascular injury
    - expanding or pulsating peri-renal mass
    - laparotomy for associated injury
  - follow-up with U/S or CT before discharge, and at 6 wk

**Complications**

- HTN in 5% of renal trauma

---

**Bladder Trauma**

**Classification**

- contusions: no urinary extravasation, damage to mucosa or muscularis
- intraperitoneal ruptures: often involve the bladder dome
- extraperitoneal ruptures involve anterior or lateral bladder wall in full bladder

**Etiology**

- blunt (MVC, falls, and crush injury) vs. penetrating trauma to lower abdomen, pelvis, or perineum
- blunt trauma is associated with pelvic fracture in 97% of cases
Clinical Features
- abdominal tenderness, distention, peritonitis, and inability to void
- can be hemodynamically unstable secondary to pelvic fracture, other sustained injuries: ABCs
- suprapubic pain

Investigations
- U/A: gross hematuria in 90%
- imaging (including CT cystogram and post-drainage films for extravasation)

Treatment
- penetrating trauma → surgical exploration
- contusion → urethral catheter until hematuria completely resolves
- extraperitoneal bladder perforations → typically non-operative with foley insertion, and follow with cystograms
  - surgery if: infected urine, rectal/vaginal perforation, bony spike into bladder, laparotomy for concurrent injury, bladder neck involvement, persistent urine leak and failed conservative management
- intraperitoneal rupture usually requires surgical repair and suprapubic catheterization

Complications
- complications of bladder injury itself are rare
- mortality is around 20%, and is usually due to associated injuries rather than bladder rupture

Urethral Injuries

Etiology
- posterior urethra
  - common site of injury is junction of membranous and prostatic urethra due to blunt trauma, MVCs, pelvic fracture
  - shearing force on fixed membranous and mobile prostatic urethra
- anterior urethra
  - straddle injury can crush bulbar urethra against pubic rami
- other causes
  - iatrogenic (instrumentation, prosthesis insertion), penile fracture, masturbation with urethral manipulation
- always look for associated bladder rupture

Clinical Features
- blood at urethral meatus
- high-riding prostate on DRE
- swelling and butterfly perineal hematoma
- penile and/or scrotal hematoma
- sensation of voiding without U/O
- distended bladder

Investigations
- must perform RUG or cystoscopy prior to catheterization

Treatment
- simple contusions
  - no treatment
- partial urethral disruption
  - very gentle attempt at catheterization by urologist
  - with no resistance to catheterization → Foley x 2-3 wk
  - with resistance to catheterization → suprapubic cystostomy or urethral catheter alignment
- periodic flow rates/urethromps to evaluate for stricture formation
- complete disruption
  - immediate repair if patient stable, delayed repair if unstable (suprapubic tube in interim)

Complications
- stricture
Infertility

Definition

- failure to conceive after one year of frequent, unprotected and properly timed intercourse
- incidence
  - 15% of all couples (35–40% female, 20% male, 25–30% combined)

Female Factors

- see Gynecology GY23

Male Factors

Male Reproduction

- hypothalamic-pituitary-testicular axis (HPTA)
  - pulsatile GnRH from hypothalamus acts on anterior pituitary stimulating release of LH and FSH
  - LH acts on Leydig (interstitial) cells → testosterone synthesis and secretion
  - FSH acts on Sertoli cells → structural and metabolic support to developing spermatogenic cells
  - FSH and testosterone support germ cells (responsible for spermatogenesis)
  - sperm route: epididymis → vas deferens → ejaculatory ducts → prostatic urethra

Etiology

- idiopathic (40-50% infertile males)
- testicular
  - varicocele (35-40% infertile males)
  - tumour
  - congenital (Klinefelter’s triad: small, firm testes, gynecomastia, and azoospermia)
  - post-infectious (epididymo-orchitis, STIs, mumps)
  - uncorrected torsion
  - cryptorchidism (<5% of cases)
- obstructive
  - iatrogenic (surgery; see below)
  - infectious (gonorrhea, chlamydia)
  - trauma
  - congenital (absence of vas deferens, CF)
  - bilateral ejaculatory duct obstruction, epididymal obstructions
  - Kartagener’s syndrome (autosomal recessive disorder causing defect in action of cilia)
- endocrine (see Endocrinology E45)
  - HPTA (2-3%) e.g. Kallmann’s syndrome congenital hypothalamic hypogonadism), excess prolactin, excess androgens, excess estrogens
- other
  - retrograde ejaculation secondary to surgery
  - medications
  - prior exposure to chemotherapy or pelvic radiation
  - drugs: marijuana, cocaine, tobacco, alcohol
  - increased testicular temperature (sauna, hot baths, tight pants or underwear)
  - chronic disease: e.g. liver, renal

History

- age of both partners
- medical: past illnesses, DM, trauma, CF, genetic syndromes, STIs, cryptorchidism
- surgical: vasectomy, herniorrhaphy, orchidopexy, prostate surgery
- fertility: pubertal onset, previous pregnancies, duration of infertility, treatments
- sexual: libido, erection/ejaculation, timing, frequency
- family Hx
- medications: cytotoxic agents, GnRH agonists, anabolic steroids, nitrofurantoin, cimetidine, sulfasalazine, spironolactone, α-blockers
- social Hx: alcohol, tobacco, cocaine, marijuana, school performance/learning disabilities (suggestive of Klinefelter syndrome)
- occupational exposures: radiation, heavy metals

Physical Exam

- general appearance: sexual development, gynecomastia, obesity, pubic hair
- scrotal exam: size, consistency, and nodularity of testicles; palpation of cord for presence of vas deferens; DRE; valsalva for varicocele
Investigations
- semen analysis (SA) at least 2 specimens, collected 1-2 wk apart
- hormonal evaluation
  - indicated with abnormal SA (rare to be abnormal with normal SA)
  - testosterone and FSH
- serum LH and prolactin are measured if testosterone or FSH are abnormal
- genetic evaluation
  - chromosomal studies (Klinefelter’s syndrome - XXY)
  - genetic studies (Y-chromosome microdeletion, CF gene mutation)
- immunologic studies (antisperm antibodies in ejaculate and blood)
- testicular biopsy
- scrotal U/S (varicocele, testicular size)
- vasography (assess patency of vas deferens)

Treatment
- assessment of partner
- lifestyle
  - regular exercise, healthy diet
  - eliminate alcohol, tobacco and illicit drugs
- medical
  - endocrine therapy (see Endocrinology, E)
  - treat retrograde ejaculation
  - discontinue anti-sympathomimetic agents, may start α-adrenergic stimulation (phenylpropanolamine, pseudoephedrine, or ephedrine)
  - treat underlying infections
- surgical
  - varicocelectomy (if indicated)
  - vasovasostomy (vasectomy reversal) or epididymovasostomy
  - transurethral resection of blocked ejaculatory ducts
- assisted reproductive technologies (ART)
  - refer to infertility specialist
  - sperm washing + intrauterine insemination (IUI)
  - in vitro fertilization (IVF)
  - intracytoplasmic sperm injection (ICSI) after CF screening of patient and partner in patients with congenital bilateral absence of vas deferens

Figure 15. Infertility workup
Pediatric Urology

Congenital Abnormalities

- not uncommon; 1/200 have congenital abnormalities of the GU tract
  six common presentations of congenital urological abnormalities

1. ANTENATAL HYDRONEPHROSIS

Epidemiology
- 1-5% fetal U/S, some detectable as early as first trimester
- most common urological consultation in perinatal period and one of most common U/S abnormalities of pregnancy

Differential Diagnosis
- UPJ or UVJ obstruction
- multi-cystic dysplastic kidney
- VUR
- PUVs (only in boys)
- duplication anomalies
- ureterocele
- ectopic ureter

Treatment
- antenatal in utero intervention rarely indicated unless evidence of lower urinary tract obstruction with oligohydramnios

2. POSTERIOR URETHRAL VALVES

Epidemiology
- the most common congenital obstructive urethral lesion in male infants

Pathophysiology
- abnormal mucosal folds at the distal prostatic urethra causing varying degrees of obstruction

Clinical Presentation
- dependent on age
  - antenatal: bilateral hydronephrosis, distended bladder, oligohydramnios
  - neonatal (recognized at birth): palpable abdominal mass (distended bladder, hydronephrosis), urinary ascites (transudation of retroperitoneal urine), respiratory distress (pulmonary hypoplasia from oligohydramnios), weak urinary stream
  - neonatal (not recognized at birth): within weeks present with urosepsis, dehydration, electrolyte abnormalities, failure to thrive; rule out pyloric stenosis, which may present similarly
  - toddlers: UTIs or voiding dysfunction
  - school-aged boys: voiding dysfunction → urinary incontinence
- associated findings include renal dysplasia and secondary VUR

Investigations
- most commonly recognized on prenatal U/S → bilateral hydronephrosis, thickened bladder, dilated posterior urethra ("keyhole sign"), oligohydramnios in a male fetus
- VCUG → dilated and elongated posterior urethra, trabeculated bladder, VUR

Treatment
- immediate catheterization to relieve obstruction, followed by cystoscopic resection of PUV when baby is stable
- if resection of PUV is not possible, vesicostomy is indicated

3. URETEROPELVIC JUNCTION OBSTRUCTION

Etiology
- unclear: adynamic ureteral segment, stenosis, strictures, extrinsic compression, aberrant blood vessels
- can rarely be secondary to tumour, stone, etc. in children

Epidemiology
- the most common congenital defect of the ureter
  - M:F = 2:1
  - up to 40% bilateral, which may be associated with worse prognosis
Clinical Presentation
- symptoms depend on severity and age at diagnosis (mostly asymptomatic finding on antenatal U/S)
  - infants: abdominal mass, urinary infection
  - children: pain, vomiting, failure to thrive
- some cases are diagnosed after puberty and into adulthood
- in adolescents and adults, the symptoms may be triggered by episodes of increased diuresis, such as following alcohol ingestion (Dietl's crisis)

Investigations
- antenatal: serial U/S most common, and renal scan ± furosemide

Treatment
- surgical correction (pyeloplasty), consider nephrectomy if <15% differential renal function

4. VESICOURETERAL REFLUX

Definition
- retrograde passage of urine from the bladder, through the UVJ, into the ureter

Classification
- primary reflux: incompetent or inadequate closure of UVJ
  - lateral ureteral insertion, short submucosal segment
- secondary reflux: abnormally high intravesical pressure resulting in failure of UVJ closure
  - often associated with anatomic (PUV) or functional (neuropathic) bladder dysfunction

Epidemiology
- estimated ~1% of newborns, but not well known
- incidence and clinical relevance higher in children with febrile UTIs and prenatal hydronephrosis
- risk factors: race (white > black), female gender, age (<2 yr), genetic predisposition

Investigations
- focused Hx, particularly of voiding dysfunction (frequency, urgency, diurnal enuresis, constipation, encopresis)
  - also screen for infections (UTI, pyelonephritis, urosepsis) and renal failure (uremia, HTN)
- initial evaluation of renal status, growth parameters, and blood pressure is warranted in any child with VUR due to relatively high incidence of renal scarring
  - height, weight, blood pressure
  - serum Cr
  - U/A, C&S
  - renal U/S
  - DMSA renal scan if at high risk (greater sensitivity in detecting structural defects associated with dysplasia, renal scarring or pyelonephritis; entails radiation exposure)
  - sibling family screening is controversial

Treatment
- spontaneous resolution in 60% of primary reflux
  - in lower grades (I-III), goal is to prevent infection or renal damage via medical treatment
  - medical treatment: daily ABx prophylaxis at half the treatment dose for acute infection (see Table 9, U12 - TMP/SMX, trimethoprim, amoxicillin, or nitrofurantoin)
  - surgical treatment: ureteral reimplantation ± ureteroplasty, or subureteral injection with bulking agents (Deflux® or Macroplastique®)
    - indications include failure of medical management, renal scarring (e.g. renal insufficiency, HTN), breakthrough UTIs, persistent high grade (IV or V) reflux
  - defer circumcision in patients with hypospadias

5. HYPOSPADIAS

Definition
- a condition in which the urethral meatus opens on the ventral side of the penis, proximal to the normal location in the glans penis
- depending on severity, may result in difficulty directing urinary stream, having intercourse or depositing sperm in vagina

Epidemiology
- very common; 1/300 live male births
- distal hypospadias more common than proximal
- white >> black
- may be associated with ventral penile curvature, disorders of sexual differentiation, undescended testicles or inguinal hernia
Treatment
- early surgical correction; optimal repair before 2 yr
- neonatal circumcision should be deferred because the foreskin may be utilized in the correction

6 EXSTROPHY-EPISPADIAS COMPLEX

Definition
- a spectrum of defects depending on the timing of the rupture of the cloacal membrane
- bladder exstrophy: congenital defect of a portion of lower abdominal and anterior bladder wall, with exposure of the bladder lumen
- cloacal exstrophy
  - exposed bladder and bowel with imperforate anus
  - associated with spina bifida in >50%
- epispadias (least severe)
  - urethra opens on dorsal aspect of the penis, often associated with penile curvature

Etiology
- represents failure of closure of the cloacal membrane, resulting in the bladder and urethra opening directly through the abdominal wall

Epidemiology
- rare: incidence 1/30,000, M:F = 3:1 predominance
- high morbidity → multiple reconstructive surgeries, incontinence, infertility, reflux

Treatment
- surgical correction at birth
- later corrections for incontinence, VUR, and low bladder capacity may be needed

Nephroblastoma (Wilms’ Tumour)

Etiology
- arises from abnormal proliferation of metanephric blastema

Epidemiology
- 5-5-10: 5% of all childhood cancers, 5% bilateral, 10% associated with congenital malformation syndromes
- most common primary malignant renal tumour of childhood
- average age of incidence is 3 yr

Clinical Features
- abdominal mass: large, firm, unilateral (80%)
- HTN (25%)
- flank tenderness (30-40%)
- microscopic hematuria (12-25%)
- nausea/vomiting

Treatment
- always investigate contralateral kidney and renal vein (for tumour thrombus)
- unilateral disease: radical nephrectomy ± radiation ± chemotherapy
- bilateral disease: nephron-sparing surgery following neoadjuvant chemotherapy

Prognosis
- 5 yr survival 80%

Cryptorchidism/Ectopic Testes

Definition
- abnormal location of testes somewhere along the normal path of descent (external inguinal ring > inguinal canal > abdominal)
- Denis Browne pouch (between external oblique fascia and Scarpa’s fascia) most common
- differential diagnosis:
  - retractile testes
  - atrophic testes
  - disorders of sexual differentiation (bilateral impalpable gonads)

Epidemiology
- 2.7% of full term newborns
- 0.7-0.8% at 1 yr
**Treatment**
- orchiopexy
- hormonal therapy not proven to be of benefit over standard surgical treatment

**Prognosis**
- reduction in fertility
  - untreated bilateral cryptorchidism: ~100% infertility
  - paternity rates: 53%, 90%, and 93% in formerly bilateral cryptorchid, formerly unilateral cryptorchid, and normal men, respectively
- increased malignancy risk
  - intraabdominal > inguinal
  - surgical correction facilitates testicular monitoring and may reduce malignancy risk
- increased risk of testicular torsion (reduced by surgical correction)

---

**Disorders of Sexual Differentiation**

**Definition**
- formerly known as intersex disorders: considered social emergency
- abnormal genitalia for chromosomal sex due to the undermasculinization of males or the virilization of females

**Classification**
1. 46 XY DSD
   - defect in testicular synthesis of androgens
   - androgen resistance in target tissues
   - palpable gonad
2. 46 XX DSD
   - most due to CAH (21-hydroxylase deficiency most common enzymatic defect) → shunt in steroid biosynthetic pathway leading to excess androgens
   - undiagnosed and untreated CAH can be associated with life-threatening electrolyte abnormalities in the newborn (salt-wasting CAH)
3. ovotesticular DSD
4. mixed gonadal dysgenesis (46 XY/45 XO most common karyotype)
   - presence of Y chromosome → partial testis determination to varying degrees

**Diagnosis**
- thorough family Hx noting any consanguinity
- maternal Hx, especially medication/drug use during pregnancy (maternal hyperandrogenemia)
- P/E: palpable gonad (= chromosomal male), hyperpigmentation, evidence of dehydration, HTN, stretched phallus length, position of urethral meatus
- laboratory tests
  - plasma 17-OH-progesterone (after 36 h of life) → increased in CAH
  - plasma 11-deoxycorticisol → increased in 11-β-hydroxylase deficiency
  - basal adrenal steroid levels
  - serum testosterone and DHT pre- and post-hCG stimulation (2,000 IU/d for 4 d)
  - serum electrolytes
  - chromosomal evaluation including sex karyotype
- U/S of adrenals, gonads, uterus, and fallopian tubes
- endoscopy and gen tography of urogenital sinus

**Treatment**
- steroid supplementation as indicated (e.g. CAH)
- sex assignment after extensive family consultation
  - must consider capacity for sexually functioning genitalia in adulthood, fertility potential, and psychological impact
- reconstruction of external genitalia between 6 and 12 mo
- long-term psychological guidance and support for both patient and family

---

**Enuresis**
- see Pediatrics, P9
Selected Urological Procedures

Bladder Catheterization

• catheter size measured by the French (Fr) scale – circumference in mm
  each 1 mm increase in diameter = approximately 3 Fr increase (standard size 14-18 Fr)
  should be removed as soon as possible to reduce the risk of UTI

Continuous Catheterization

• indications
  • accurate monitoring of U/O
  • relief of urinary retention due to medication, neurogenic bladder, or intravesical obstruction
  • temporary therapy for urinary incontinence
  • perineal wounds
  • clot prevention (22-24 Fr) for CBI
  • intra- and post-operative
  • comfort for end of life care

Alternatives to Continuous Catheterization

• intermittent catheterization
  • PVR measurement
  • to obtain sterile diagnostic specimens for U/A, urine C&S
  • management of neurogenic bladder or chronic urinary retention
  • condom catheter
  • suprapubic catheter

Causes of Difficult Catheterizations and Treatment

• patient discomfort → use sufficient lubrication (± xylocaine)
• collapsing catheter → lubrication as above ± firmer or larger catheter (silastic catheter)
• meatal/urethral stricture → dilate with progressively larger catheters/balloon catheter
• BPH → use coudé catheter as angled tip can help navigate around enlarged prostate
• urethral disruption/obstruction → filling of and followers or suprapubic catheterization
• anxious patient → anxiolytic medication

Complications of Catheterization

• infection: UTI, bladder fistula, bladder perforation (rare)
• meatal/urethral trauma

Contraindications

• trauma: blood at the urinary meatus, scrotal hematoma, pelvic fracture, and/or high riding prostate

Circumcision

Definition

• removal of some or all of the foreskin from the penis

Epidemiology

• 30% worldwide
• frequency varies with geography, religious affiliation, socioeconomic status

Medical Indications

• phimosis and recurrent paraphimosis
• recurrent UTIs (particularly in infants and in association with other urinary abnormalities)
• balanitis xerotica obliterans or other chronic inflammatory conditions

Contraindications

• unstable or sick infant
• congenital genital abnormalities (hypospadias)
• family Hx of bleeding disorders warrants laboratory investigation prior to circumcision

Complications

• bleeding
• infection
• preputial entrapment, skin bridges
• fistula
• glans injury
• penile sensation deficits

Figure 18. Transurethral (Foley) catheters

Main Circumcision for Prevention of Heterosexual Acquisition of HIV in Men

Purpose: To evaluate the effectiveness and safety of male circumcision for preventing acquisition of HIV in heterosexual men.

Me hods: The analyzed data is from three randomized controlled trials to assess the efficacy of male circumcision for preventing HIV acquisition in men in Africa.

Results: Medical male circumcision reduces the acquisition of HIV by heterosexual men (38-66% over 24 mo).

Circumcision Status and Risk of HIV and Sexually Transmitted Infections among Men who have Sex with Men: A Meta-Analysis

JAMA 2012;308:1680-1685

Purpose: To describe the association between male circumcision and HIV infection and other sexually transmitted infections (STIs) among men who have sex with men (MSM).

Methods: Meta-analysis of 15 studies (n=53,567)

Results: The associations between circumcision and HIV infection and STIs were not statistically significant. Male circumcision had a protective association with HIV in a subset of MSM conducted before the introduction of highly active anti-retroviral therapy.

Conclusions: There is insufficient evidence to support that male circumcision protects against HIV infection or other STIs.

Male Circumcision

Pediatrics 2012;30:756-785

Study: Guidelines by the American Academy of Pediatrics (AAP)

Recommendations: The American Academy of Pediatrics radically changed their position on male circumcision in 2012. The report from the AAP now states that the preventive health benefits outweigh the risks of the procedure and that the procedure is well-tolerated with adequate pain management and sterility. Stated benefits include the prevention of urinary tract infection, penile cancer, transmission of sexually transmitted infections, including HIV. There is believed to be no effect on penile sexual function, sensitivity or sexual satisfaction. Acute complications are rare and more common if the procedure is done by an untrained provider.

Note: The Canadian Pediatric Society (CPS) has not yet updated their position on male circumcision since 1998, which stated that the CPS is opposed to routine circumcision. A new statement is expected soon.
Cystoscopy

Objective
- endoscopic inspection of the lower urinary tract (urethra, prostate, bladder, and ureteral orifices), samples for cytology
- scopes can be flexible or rigid

Indications
- gross hematuria
- LUTS (storage or voiding)
- urethral and bladder neck strictures
- bladder stones
- bladder tumour surveillance
- evaluation of upper tracts with retrograde pyelography (ureteric stents, catheters)

Complications
- during procedure
  - bleeding
  - anesthetic related
  - perforation (rare)
- post procedure (short-term)
  - infections (antibiotic prophylaxis recommended)
  - urinary retention
  - post-procedure (long-term)
  - stricture

Radical Prostatectomy

Objective
- the removal of the entire prostate and prostatic capsule via a lower midline abdominal incision, laparoscopically or robotically
  - internal iliac and obturator vessel lymph nodes may also be dissected and sent for pathology (depend on risk: clinical stage, grade, PSA)
  - seminal vesicle vessels are also partially or completely removed

Indications
- treatment for localized prostate cancer

Complications
- immediate (intraoperative)
  - blood loss
  - rectal injury (extremely rare)
  - ureteral injury (extremely rare)
- perioperative
  - lymphocele formation if concurrent pelvic lymphadenectomy performed
- late
  - moderate to severe urinary incontinence (3-10%)
  - mild urinary incontinence (20%)
  - ED (~50%, depending on whether one, both, or neither of the neurovascular bundles are involved in extracapsular extension of tumour)

Transurethral Resection of the Prostate (TURP)

Objective
- to partially resect the periurethral portion of the prostate (transition zone) to decrease symptoms of urinary tract obstruction
- accomplished via a transurethral (cystoscopic) approach using an electrocautery loop, irrigation (glycine), and illumination

Indications
- obstructive uropathy (large bladder diverticula, renal insufficiency)
- refractory urinary retention
- recurrent UTIs
- recurrent gross hematuria
- bladder stones
- intolerance/failure of medical therapy
Complications

- acute
  - intra- or extraperitoneal rupture of the bladder
  - rectal perforation
  - incontinence
  - incision of the ureteral orifice (with subsequent reflux or ureteral stricture)
  - hemorrhage
  - epididymitis
  - sepsis
  - transurethral resection syndrome (also called “post-TURP syndrome”)
    - caused by absorption of a large volume of the hypotonic irrigation solution used, usually through perforated venous sinuses, leading to a hypervolemic hyponatremic state
    - characterized by dilutional hyponatremia, confusion, nausea, vomiting, HTN, bradycardia, visual disturbances, CHF, and pulmonary edema
    - treat with diuresis and (if severe) hypertonic saline administration
- chronic
  - retrograde ejaculation (>75%)
  - ED (5-10% risk increases with increasing use of cautery)
  - incontinence (<1%)
  - urethral stricture
  - bladder neck contracture

Extracorporeal Shock Wave Lithotripsy

Objective

- to treat renal and ureteral calculi (proximal, middle or distal) which cannot pass through the urinary tract naturally
- shockwaves focused onto stone → fragmentation, allowing stone fragments to pass spontaneously and less painfully

Indications

- potential first-line therapy for renal and ureteral calculi <2.5 cm
- individuals with calculi in solitary kidney
- individuals with HTN, DM or renal insufficiency
*patient preference and wait-times play a large role in stone management

Contraindications

- acute UTI or urosepsis
- bleeding disorder or coagulopathy
- pregnancy
- obstruction distal to stone (ESWL can be used after stent or nephrostomy inserted)

Complications

- bacteriuria
- bacteremia
- post-procedure hematuria
- ureteric obstruction (by stone fragments)
- peri-nephric hematoma

<td>Urinary retention, UTI</td>
</tr>
</tbody>
</table>

Note: All anti-cholinergics are equally effective and long-acting formulations are better tolerated. Newer muscarinic M3 receptor specific agents (solifenacin, darifenacin) are equally efficacious as older drugs, however, RCTs based on head-to-head comparison to long-acting formulations are lacking.

Peripheral Arterial Disease (PAD)

Acute Arterial Ischemia

**Definition**
- acute occlusion of a peripheral artery, usually without a history of claudication
- urgent management required
  - skeletal muscle can tolerate 6 h of ischemia before irreversible damage and myonecrosis; exception is in acute-on-chronic occlusion, where previously developed collaterals allow more time
  - tends to be lower extremity > upper extremity; femoropopliteal > aortoiliac
  - paralysis and neuromuscular compromise are signs of late ischemia

**Etiology and Risk Factors**
- embolism vs. thrombosis
  - examples of conditions that predispose to embolism are: arrhythmias, endocarditis, and arterial aneurysms
  - existing atherosclerotic plaques (i.e. chronic PAD) can rupture causing thrombosis
  - previous vascular grafts/reconstructions can fail and thrombose leading to acute presentation
  - hypercoagulable states can contribute to arterial thrombosis

**Clinical Features**

**Table 1. Arterial Embolism vs. Thrombosis**

<table>

<td>Decreased or absent</td>
</tr>
</tbody>
</table>

**Investigations**
- history and physical exam are essential: depending on degree of ischemia one may have to forego investigations and go straight to the operating room
- ABI: extension of physical exam, easily performed at bedside
- ECG: troponin: rule out recent MI or arrhythmia
- CBC: ruled out leukocytosis, thrombocytosis or recent drop in platelets in patients receiving heparin (may suggest HIT/S)
- PT/INR, PTT: patient anticoagulated/sub-therapeutic INR
- Echo: identify wall motion abnormalities, intracardiac thrombus, valvular disease, aortic dissection (Type A)
- CT angiogram: underlying atherosclerosis, aneurysm, aortic dissection
- conventional catheter based angiography: can be obtained in OR; prelude to thrombolytics, as part of endovascular intervention or for planning treatment

**Treatment**
- immediate heparinization with 5000 IU bolus (80 Units/kg) and continuous infusion to titrate PTT to 70-90 s
- if impa red neurovascular status: emergent revascularization
- if intact neurovascular status: time for workup (including angiogram-CTA)
- definitive treatment
Peripheral Arterial Disease (PAD)

Reperfusion Complications
- compartment syndrome (see Orthopedic Surgery, OR9) with prolonged ischemia; requires 4-compartment (anterior/lateral/superficial and deep posterior) fasciotomy
- risk of arrhythmia and death with reperfusion injury
- renal failure and multi-organ failure due to toxic metabolites from ischemic muscle

Prognosis
- 12-15% mortality rate
- 5-40% morbidity rate (amputation)

Chronic Arterial Occlusion/Insufficiency

Definition
- chronic ischemia due to inadequate arterial supply to meet cellular metabolic demands (during walking (Claudication) or at rest (limb threat/critical limb ischemia))

Etiology and Risk Factors
- predominantly due to atherosclerosis (for pathogenesis, see Cardiology and Cardiac Surgery, C26); primarily occurs in the lower extremities
- major risk factors: smoking, DM older age
- minor risk factors: HTN, hyperlipidemia, obesity, sedentary lifestyle, PMHx or FMHx CAD/CVD

Clinical Features
- claudication: must differentiate vascular from neurogenic claudication or MSK
  1. pain with exertion: usually in calves or any exercising muscle group
  2. relieved by short rest: 2-5 min, and no postural changes necessary
  3. reproducible: same distance or time to elicit pain, same location of pain, same amount of rest to relieve pain
- critical limb ischemia (CLI)
  1. includes rest pain, night pain, tissue loss (ulceration or gangrene)
  2. pain most commonly over the forefoot, waking person from sleep, and often relieved by hanging foot off bed
  3. ankle pressure <40 mmHg, toe pressure <30 mmHg, ABI <0.40
    - pulses may be absent at some locations, bruits may be present
    - signs of poor perfusion: hair loss, hypertrophic nails, atrophic muscle, ulcerations and infections, slow capillary refill, prolonged pallor on dependency, venous through (collapse of superficial veins of foot)

Investigations
- non-invasive
- routine blood work fasting metabolic profile
- ABI: take highest brachial and highest ankle (dorsalis pedis artery or posterior tibial artery) pressures for each side generally (see Table 2) (may be falsely normal or elevated in those with calcified vessels e.g. diabetics)
- CTA and MRA
  - excellent for large arteries (aorta, iliac, femoral, popliteal) but may have difficulty with tibial arteries (especially in the presence of disease)
  - require IV injection of nephrotoxic contrast (iodinated contrast for CT, gadolinium for MR)
  - used primarily for planning interventions
- invasive
  - arteriography: superior resolution to CTA/MRA, better for tibial arteries, can be done intraoperatively or as part of endovascular intervention

Aortic Disease

Treatment
• conservative
  ▪ risk factor modification (smoking cessation, HbA1c control, treatment of HTN, hyperlipidemia (sta in), antiplatelet therapy [ECASA])
  ▪ exercise program (30 min 3x/wk): improves collateral circulation and oxygen extraction at the muscle level
  ▪ foot care (especially in DM): keep wounds clean/dry, avoid trauma and pressure on wounds
• pharmacotherapy
  ▪ antiplatelet agents (e.g. ECASA, clopidogrel)
  ▪ cilostazol (cAMP-phosphodiesterase inhibitor with antiplatelet and vasodilatory effects): improves walking distance for some patients with claudication (not available in Canada)
• surgical/endovascular
  ▪ indications: severe lifestyle impairment, vocational impairment, critical ischemia
  ▪ endovascular (angioplasty ± stenting)
  ▪ endarterectomy: removal of plaque and repair with patch (usually distal aorta or common/ profunda femoral)
  ▪ bypass graft sites: aortofemoral, axillofemoral, femoropopliteal, distal arterial – graft choices: vein graft (reversed or in situ), synthetic (polytetrafluoroethylene graft (e.g. Gore-Tex®) or Dacron®)
  ▪ amputation: if not suitable for revascularization, persistent serious infections/gangrene, unremitted rest pain poorly controlled with analgesics

Prognosis
• claudication: conservative therapy: 60-80% improve, 20-30% stay the same, 5-10% deteriorate, 5% will require intervention within 5 yr, <4% will require amputation
• for patients with CLI, at 2 yr: 25% risk of mortality, 25% risk of bilateral limb amputation, 25% risk of unilateral limb amputation, 25% without complications. 33% 5 yr survival rate

Aortic Disease

Aortic Dissection

Definition
• tear in aortic intima allowing blood to dissect into the media
• Stanford classification: Type A (involve the ascending aorta) vs. Type B (do not)
• acute <2 wk (initial mortality 1% per hr for Type A dissections)
• chronic >2 wk

Etiology
• most common: HTN
• other: connective tissue disease (e.g. Marfans, Ehlers-Danlos), cystic medial necrosis, atherosclerosis, congenital conditions (e.g. coarctation of aorta, bicuspid aortic valves, patent ductus arteriosus), infection (e.g. syphilis), trauma, arteritis (e.g. Takayasus)

Epidemiology
• M:F = 3:1
• small increased incidence in African-Canadians (related to higher incidence of HTN); lowest incidence in Asians
• peak incidence 50-65 yr old; 20-40 yr old with connective tissue diseases

Clinical Features
• sudden onset tearing chest pain that radiates to back with:
  ▪ hypertension with asymmetric BPs and pulses between arms (>30 mmHg difference indicates poor prognosis)
  ▪ ischemic syndromes due to occlusion of aortic branches: coronary (MI), carotids (ischemic stroke, Horner’s syndrome), splanchic (mesenteric ischemia), renal (AKI), peripheral (ischemic leg), intercostal vessels (spinal cord ischemia)
  ▪ “unseating” of aortic valve cusps (new diastolic murmur in 20-30%) in Type A dissection
  ▪ rupture into pleura (dyspnea, hemoptysis) or retroperitoneum (hypotension, shock) or pericardium (cardiac tamponade)
  ▪ syncope
• aortic dissection is considered a ‘great imitator’ of other conditions, thus increased risk to patient and MD (medicolegal)

Investigations
• CTA is the mainstay of both diagnosis and determining the extent of dissection
• ECG and troponin to rule out other causes: (LVH ± ischemic changes, pericarditis, heart block)
• CXR: pleural cap (pleural effusion in lung apices), widened mediastinum, left pleural effusion with extravasation of blood
• TEE: can visualize aortic valve and thoracic aorta but not abdominal aorta
• consider: lactate (elevated in ischemic gut, shock), amylase (rule out pancreatitis), troponin (rule out MI)
Aortic Disease

Treatment

- Type A dissection needs referral to cardiac surgeon for urgent repair
  - resection of segment with intimal tear; reconstitution of flow through true lumen; replacement of the affected aorta with prosthetic graft
  - post-operative complications: renal failure, intestinal ischemia, stroke, paraplegia, persistent leg ischemia, death
  - 2/3 of patients die of operative or post-operative complications
  - initial mortality rate without surgery is 3% per hr for first 24 h, 30% 1 wk, 80% 2 wk

- Type B dissection is managed medically
  - acute therapy is typically with intravenous antihypertensives titrated to BP measured by arterial line in critical care setting
  - may transition to oral meds after initial control
  - β-blocker to lower BP and decrease cardiac contractility (nondihydropyridine CCB if clear contraindications to β-blockers)
  - ACEI and/or other vasodilators if insufficient BP or HR control
  - selective intervention (endovascular or surgical) for complications or refractory symptoms/progression despite medical therapy
  - may be a subset of patients who could be well treated with early aortic stent-grafting after initial medical stabilization – evolving area of the literature

Aortic Aneurysm

Definition

- localized dilatation of an artery having a diameter at least 1.5x that of the expected normal diameter
  - true aneurysm: involving all vessel wall layers (intima, media, adventitia)
  - false aneurysm (also known as pseudo-aneurysm): disruption of the aortic wall or the anastomotic site between vessel and graft with containment of blood by a fibrous capsule made of surrounding tissue
  - aneurysms can rupture, thrombose, embolize, erode, and fistulize

Classification

- thoracic aortic aneurysm (TAA): ascending, transverse arch, descending
- abdominal aortic aneurysm (AAA): 90-98% are infrarenal
- suprarenal: involves one or more visceral arteries, but does not involve the chest
- pararenal: renal arteries arise from aneurysmal aorta, but the SMA origin is not aneurysmal
- juxtarenal: the renal arteries originate from normal aorta, but are immediately adjacent to aneurysmal aorta (there is no nonaneurysmal aorta distal to the origin of the renal arteries)
- infrarenal: the aneurysm originates distal to the renal arteries (there is nonaneurysmal aorta distal to the origins of the renal arteries)

Etiology and Risk Factors

- risk factors: smoking, HTN, PVD, CAD, CVD, age >70, family history
- degenerative
- traumatic
- mycotic (Salmonella, Staphylococcus, usually suprarenal aneurysms)
- connective tissue disorder (Marfan syndrome, Loeys-Dietz Syndrome, Ehlers Danlos syndrome)
- vasculitis
- infectious (syphilis, fungal)
- ascending thoracic aneurysms are associated with bicuspid aortic valve

Clinical Features

- 75% asymptomatic
- most commonly in the abdominal aorta
- common presentation: due to acute expansion or rupture
  - syncope
  - pain (chest, abdominal, flank, back)
  - hypotension
  - palpable pulsatile mass above the umbilicus
  - airway or esophageal obstruction, hoarseness (left recurrent laryngeal nerve paralysis), hemoptysis, or hematemesis (indicates thoracic or thoracoabdominal aortic aneurysm)
  - distal pulses may be intact

Investigations

- blood work: CBC, electrolytes, urea, creatinine, PTT, INR, type and cross
- abdominal U/S (approaching 100% sensitivity, up to ±0.6 cm accuracy in size determination) – useful for screening and surveillance
- CT with contrast (accurate visualization, size determination, EVAR planning)
- peripheral arterial Doppler/duplex (rule out aneurysms elsewhere, e.g. popliteal)

ACC/AHA 2005 Guidelines define an AAA when the minimum AP diameter of abdominal aorta ≥3.0 cm

True Aneurysm

- Saccular
- Fusiform

Pseudo-Aneurysm

Classic Triad of Ruptured AAA

- Hypotension/collapse
- Back/abdominal pain
- Palpable, pulsatile abdominal mass (caution in patients with raised BMI)

CCS PAD Guidelines 2006 Recommend AAA Screening Among:

- Men aged 65-74 yr
- Women aged 65 yr with cardiovascular disease and positive family history of AAA
- Men aged 50 yr and above with a positive family history
Treatment
- conservative (for asymptomatic aneurysms that do not meet the size threshold for repair)
  - cardiovascular risk factor reduction: smoking cessation; control of HTN, DM, hyperlipidemia, regular exercise, watchful waiting, U/S surveillance with frequency depending on size and location
- surgical
  - indications
    - ruptured
    - symptomatic
    - size >5-5.9 cm
    - ascending thoracic aortic aneurysms
      - symptomatic, enlarging, diameter >6 cm or >2x normal lumen size, >4.5 cm and aortic regurgitation (annuloaortic ectasia); >4.5-5 cm in Marfan syndrome
  - risk of rupture depends on: size, family history of rupture, rate of enlargement (>1 cm/yr in diameter), symptoms, and comorbidities (HTN, COPD, dissection), smoking
  - elective AAA repair mortality 2-5% for open repair (1-2% for EVAR); elective TAA repair mortality <10% (highest with proximal aortic and thoracoabdominal repairs)
- surgical options
  - open surgery (laparotomy or retroperitoneal) with graft replacement
    - complications
      - early: renal failure, spinal cord injury (paraparesis or paraplegia), impotence, arterial thrombosis, anastomotic rupture or bleeding, peripheral emboli
      - late: graft infection/thrombosis, aortoenteric fistula, anastomotic (pseudo) aneurysm
  - endovascular aneurysm repair (EVAR)
    - newer procedure; high success rates in patients with suitable anatomy
    - advantages: preferred to open surgery in ruptured AAA for patients with suitable anatomy, decreased morbidity and mortality, procedure time, need for transfusion, ICU admissions, length of hospitalization, and recovery time
    - disadvantages: endoleak rates as high as 20-30%, device failure increasing as longer follow-up periods are achieved, re-intervention rates 10-30%, cost-effectiveness is an issue, radiation exposure (especially in younger patients due to need for life-long follow-up)
    - complications
      - early: immediate conversion to open repair (<1%), groin hematoma, arterial thrombosis, iliac artery rupture, and thromboemboli
      - late: endoleak, graft kinking, migration, thrombosis, rupture of aneurysm

Carotid Stenosis

Definition
- narrowing of the internal carotid artery lumen due to atherosclerotic plaque formation, usually near common carotid bifurcation into internal and external carotids

Risk Factors
- for atherosclerosis: HTN, smoking, DM, CVD or CAD, dyslipidemia, older age

Clinical Features
- may be asymptomatic
- if symptomatic – hemispheric or ocular presentation

Investigations
- CBC, PT/INR, PTT (hypercoagulable states)
- fundoscopy: cholesterol emboli in retinal vessels (Hollenhorst plaques)
- auscultation over carotid bifurcation for bruits (do not correlate with degree of stenosis)
- carotid duplex: determines severity of disease (mild/moderate/severe stenosis or occlusion) ± cross sectional imaging with CT or MR

Treatment
- risk factor modification for all patients to control HTN, lipids, DM
- pharmacological - antiplatelet agents (ASA ± dipyridamole, clopidogrel) ~25% relative risk reduction
- surgical - carotid endarterectomy (generally if symptomatic and >70% stenosis) or endovascular angioplasty ± stenting

Prevention of Disability and Fatal Strokes by Successful Carotid Endarterectomy in Patients Without Recent Neurological Symptoms: Randomized Controlled Trial
Lancet 2004;363:1491-1502
Study: Asymptomatic Carotid Surgery Trial (ACST), a RCT with follow-up at 5 yr.
Patients: 3,120 asymptomatic patients with significant carotid artery stenosis were randomized equally between immediate carotid endarterectomy (CEA) and indefinite deferral of CEA and were followed for up to 5 yr (mean 3.4 yr).
Main Outcome: Any stroke (including fatal or disabling).
Conclusions: In asymptomatic patients with significant carotid artery stenosis, immediate CEA reduced the net 5-yr stroke risk from about 12% to about 8%. Half of this 5-yr benefit involved disabling or fatal strokes.
Peripheral Venous Disease

Deep Venous Thromboembolism

• see Hematology, H35

Varicose Veins

Definition
• distention of tortuous superficial veins resulting from incompetent valves in the deep, superficial, or perforator systems

Etiology
• primary (99% of cases) varicosities: venous valve incompetence or obstruction
  ■ contributing factors: increasing age, systemic hormonal contraceptive use, prolonged standing, pregnancy, obesity
• secondary varicosities: DVT, malignant pelvic tumours with venous compression, congenital anomalies, arteriovenous fistulae, trauma

Epidemiology
• primary varicose veins are the most common form of venous disorder of lower extremity
  65% of north American adult population gets some degree of venous insufficiency

Clinical Features (often the degree of symptoms do not correlate with the clinical findings)
• diffuse aching, fullness/tightness, nocturnal cramping
  ■ aggravated by prolonged standing (end of day), premenstrual
• visible long, dilated and tortuous superficial veins along thigh and leg (great or small saphenous veins and tributaries)
• ulceration, hyperpigmentation, and induration (i.e. lipodermatosclerosis)

Complications
• recurrent superficial thrombophlebitis/superficial vein thrombosis
• features of chronic venous insufficiency: ulceration, eczema, lipodermatosclerosis, stasis dermatitis and hyperpigmentation
• bleeding or hematoma secondary to trauma

Treatment
• largely a cosmetic problem
• conservative: elastic compression stockings
• indications for surgery: failure of conservative treatment, symptomatic varix (pain, bleeding, recurrent thrombophlebitis), tissue changes (hyperpigmentation, ulceration), cosmetic
• surgical: high ligation and stripping of the long saphenous vein and its tributaries, ultrasound-guided foam sclerotherapy, endovenous laser therapy
• 10 year post-operative recurrence of 20%

Chronic Venous Insufficiency

Definition
• venous insufficiency and skin damage

Etiology
• calf muscle pump dysfunction and valvular incompetence (reflux) due to phlebitis, varicosities, or DVT
• venous obstruction

Clinical Features
• pain (most common), ankle and calf edema – relieved by foot elevation
• pruritus, brownish hyperpigmentation (hemosiderin deposits)
• stasis dermatitis, subcutaneous fibrosis if chronic (lipodermatosclerosis)
• ulceration: shallow, above medial malleolus, weeping (wet), painless, irregular outline
• signs of DVT/varicose veins/thrombophlebitis

Investigations
• not required if conservative treatment only
• Doppler U/S (most commonly used in pre-operative assessment)
Lymphedema

Treatment
- conservative
  - elastic compression stockings, ambulation, periodic rest elevation, avoid prolonged standing
  - ulcers: multilayer compression bandage, antibiotics prn
- surgical
  - if conservative measures fail, or if recurrent/large ulcers to reduce the risk of recurrence
  - surgical ligation of perforators in region of ulcer (GSV/LSV ligation and stripping)
  - endovenous: laser or radiofrequency ablation or foam sclerotherapy

Definition
- obstruction of lymphatic drainage resulting in edema with high protein content

Etiology
- primary
  - Milroy’s syndrome: congenital hereditary lymphedema
  - lymphedema praecox (75% of cases): starts in adolescence
  - lymphedema tarda: starts >35 yr
- secondary
  - infection: filariasis (#1 cause worldwide)
  - malignant infiltration: axillary, groin or intrapelvic
  - radiation/surgery (axillary, groin lymph node removal): #1 cause in North America

Clinical Features
- classically non-pitting edema
- impaired limb mobility, discomfort/pain, psychological distress

Treatment
- avoid limb injury (can precipitate or worsen lymphedema)
- cellulitis: treat early to avoid further lymphatic damage
- skin hygiene
  - daily skin care with moisturizers
  - early medical assessment and treatment for infection (topical for fungal infection; systemic for bacterial infection)
- external support
  - intensive: compression bandages
  - maintenance: compression garment
- exercise
  - gentle daily exercise of affected limb, gradually increasing ROM
  - must wear a compression sleeve/bandages when doing exercises
- massage: manual lymph drainage therapy

For 34 years, Toronto Notes has been a premier study resource for the Canadian MCCQE and USMLE Step II medical licensing exams. This edition provides concise and comprehensive information on the objectives covered by these exams, including the most recent best practice guidelines and up-to-date trials for clinical practice. Toronto Notes is an excellent resource for clinical rotations and this text contains 31 subject-specific chapters:

- Anesthesia and Perioperative Medicine
- Cardiology and Cardiac Surgery
- Clinical Pharmacology
- Dermatology
- Emergency Medicine
- Endocrinology
- Ethical, Legal, and Organizational Medicine
- Family Medicine
- Gastroenterology
- General Surgery and Thoracic Surgery
- Geriatric Medicine
- Gynecology
- Hematology
- Infectious Diseases
- Medical Genetics
- Medical Imaging
- Nephrology
- Neurology
- Neurosurgery
- Obstetrics
- Ophthalmology
- Orthopedics
- Otolaryngology
- Pediatrics
- Plastic Surgery
- Population Health and Epidemiology
- Psychiatry
- Respirology
- Rheumatology
- Urology
- Vascular Surgery
